becomes necessary when the Scott's flashing shutter is either put on or taken off from the front. The projector is fitted with what is termed slow gear for both vertical and horizontal

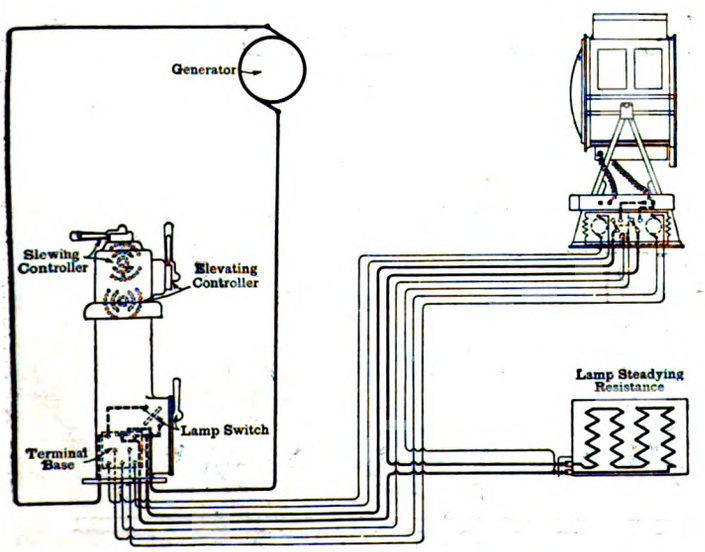

FIG. 7.—DIAGRAM OF CONNECTIONS FOR ELECTRICALLY-CONTROLLED PROJECTOR.

training, each being fitted with throw-out handles so that the movements can be thrown out quickly by hand. A training arc with degree strip is placed round the top of the base, the

Fig. 2 shows a 36 in. projector of the electrically controlled type. A base of a 36 in. projector is shown in Fig. 1. If electrically controlled, there are two motors placed within the base of the watertight type and operated by means of the controller which is shown diagrammatically in Fig. 7. This controller can be placed at any convenient distance away from the projector, and is fitted with a single-pole switch on the base, and has two operating handles at the top, one for elevating and one for training. In this way a large range and variation of speed in the vertical and horizontal planes can be obtained, and both operations can be carried out at one time. The speeds can be varied, say, from one revolution in about 20 minutes up to one revolution in, say, 25 seconds. The 36 in. hand or automatic projector lamp is also fitted with an arc deflector fitted in the centre, which keeps the arc steady during the time the lamp is burning.

Fig. 6 shows Crompton searchlights in action. Our London readers will not have forgotten the display of Britain's naval power at Southend last year, and the illustration indicates that Crompton searchlights were well to the fore on that occasion.

The whole question of searchlight design is a subject on which much unobtrusive and necessarily secret work is being done. Experiments are being made on the carrying power of various types of mirrors and the suitability of new details which it is proposed shall be used in the lamps. A sort of searchlight drill is being got out which enables the fire commander to employ his light to the best possible advantage, a great advance which has been much helped by electrical systems of operation. The searchlights on board ship are now practically one sub-divided unit. They can be either worked as a whole or separately as desired.

J. & P. Searchlight Projectors

As considerable experience is required for the production of an efficient searchlight, and as until the last few years the demand for this apparatus has been very limited, it is not surprising that the manufacture of searchlights has been confined to only a few firms. Among these must be included Messrs. Johnson & Phillips.

The illustration herewith shows the yacht pattern of searchlight manufactured at the Victoria Works, Charlton, of this firm. It will be noticed that the projector consists mainly of the usual two parts—the projector body and the supporting pedestal, the latter, which is either a casting or a wrought-iron sheet of conical shape, being suitably arranged to hold the projector in any direction in which the beam of light is required to be thrown. For this purpose the supporting side arms carrying the body trunnions are fixed to a revolving turntable which is mounted on ball bearings. As to the projector body itself, this is of stout sheet steel, suitably strengthened at the ends by wrought-iron rings. A lamp "well" is riveted underneath and fitted with a focussing screw, whilst ample ventilation is also provided. The mirror is of silvered glass and is parabolic, being mounted in a suitable frame.

Next to the mirror, the lamp is probably of most importance. The J. & P. lamp is of the horizontal type and is arranged for combined automatic and hand feed, being also provided with a magnetic arc centerer. Flexible cables run from the lamp through a bushed hole in the top of the pedestal, on which the terminals for connecting up the supply cables are fitted. For viewing the arc, observation windows are inserted in the sides of the projector body, whilst the front of the projector body is closed by means of a glass door, built up of a plate-glass circle, or set of strips, mounted in a metal ring attached to the body. It will be evident from the illustration herewith

THE "PARSONS-SLOPER"

SECRET

TELEPHONE SYSTEM

is recognised to be the MOST SIMPLE yet MOST PERFECT system on the market and is admirably suited to meet all the requirements of MODERN SHIP-BUILDERS. The fact that

PARSONS-SLOPER SECRET INTERCOMMUNICATION TELEPHONES

are installed on the

"MAURETANIA" and "LUSITANIA"

speaks volumes for its wonderful EFFICIENCY AND RELIABILITY.
Chief amongst the *many* advantages of this system may be mentioned that,

By means of a tatler, WHILST RINGING and BEFORE SPEAKING, you are informed whether the distant instrument is "ENGAGED," "AT LIBERTY" or "UNATTENDED."

Overhearing or Cross Talk is AN ABSOLUTE IMPOSSIBILITY.

These instruments are of BRITISH MANUFACTURE throughout and the greatest care is devoted to the smallest details to ensure absolute perfection when in use.
Full particulars and descriptive literature will be forwarded post free on application.

Ships' Telephones.

BY H. S. THOMPSON.

(Of the National Telephone Co.)

Summary.—After describing the general scheme adopted on board a ship, which, from the telephone point of view, may be looked upon as a large hotel, the instruments and other details, such as wiring and protection from stray currents, are considered. Owing to the special conditions at sea, such installations differ materially from those on land. For connecting a ship to a shore exchange a special flexible cable, with connecting boxes, is used.

Within the last few years a new branch of telephony has been opened up by the adoption of the private branch exchange service on some of the larger ocean-going liners.

When it is remembered that such vessels are in reality huge floating hotels, the number of whose guests often reach well into four figures, it will readily be seen that a very wide field here exists for an efficient and time-saving telephone service, affording instant communication between the various officials, between the passengers and the small army of stewards and others who attend to their wants, between the passengers themselves, and with the local and trunk telephone service when the ship is in port. Installations affording in some measure all these facilities are already in use on certain of our larger liners, and the purpose of this article is to give some idea of the methods which have been adopted and the apparatus used. These installations are worked on the central battery system, and the equipment provided is similar in many respects to that used in connection with the ordinary private branch exchange installations which are now such an essential feature of all large business establishments.

In considering such a scheme the first essential is to determine the position of the room in which the switchboard and its associated apparatus is to be located. In order to economise in wiring it is important that this room be as nearly central in regard to the telephones to be served, as is practicable. It should be in a sheltered portion of the ship, so as not to be exposed to the weather, and should preferably be one in which artificial lighting is unnecessary during daylight hours. Its size will, of course, depend upon the number of telephones to be served, but it is very desirable that reasonable space be left for the operator and that the apparatus be not unnecessarily cramped.

Having decided upon the switchroom, plans of the various decks are prepared and the positions of the different telephones marked thereon. Working on these plans the number, size, and positions of the distributing boxes are fixed and the wiring scheme is planned out. Between the switchroom and the distributing boxes the wires are run in cables. These are made up in various sizes. The conductors used are of tinned copper, No. 20 S.W.G., insulated with vulcanised indiarubber, which brings the external diameter up to No. 12 S.W.G. These are laid up in twisted pairs and the whole cable is encased in lead sheathing. The cables are generally run along the main corridors and are fixed in position before the wood panelling is fitted. Where this is not possible it is usual to employ wooden casing, or to cleat the cable to the bulkheads without any covering. One or more main cables are run from the switchroom according to the size of the system and the location of the telephones. At convenient points en route branches are taken out from the main cable and run to the various distributing points, a corresponding reduction being made in the number of wires in the main cable after each branch. When deciding upon the number of wires in these cables it is necessary to keep in view what the ultimate requirements will be and to make provision for any additional telephones which may subsequently be required, otherwise their installation at a later date becomes a matter of considerable expense and often of great difficulty.

In installing and jointing these cables all the usual precautions in regard to preserving the proper twists in each pair of wires must be taken. Plumbers' joints are made in the lead sheathing over all joints, and the ends of the cables are sealed with compound to prevent the entrance of moisture.

Between the distributing boxes and the instruments, V.I.R. wires, similar to those in the cables, are run in wooden casing or steel conduit according to the surroundings. In the cabins and staterooms it is usual to employ wooden casing, which is either an actual part of, or is made to harmonise with, the panellings and decorations. The wires are led from the casings to the instruments behind the bulkhead panelling and are brought out immediately behind the instrument or terminal block so as to be completely concealed.

FIG. 1.—TYPICAL INSTRUMENT.

When the installation of the wiring is completed very careful tests are made for insulation and for cross talk to ensure that there are no crosses between pairs and that the proper twists have been maintained throughout.

The instruments used are of the central battery type, similar in all essentials to those used on shore in connection with central battery exchanges, but somewhat different in appearance and details. The wall set illustrated in Fig. 1 is the instrument most generally used. This instrument is of the Western Electric Co.'s manufacture and has a special gimbal device fitted on the switch hook to prevent its action being interfered with by the rolling of the ship. This device is clearly shown in Fig. 1, and consists of a spring clip pivoted horizontally so that the receiver may swing and retain a vertical position when the ship rolls. Without this arrangement there

Digitized by Google

would be a danger of the switch hook lifting when the ship rolled, owing to the shortening of the horizontal distance between the centre of gravity of the receiver and the fulcrum of the lever. Allowance is made for a movement through 30 deg. in either direction. The spring clip is a safeguard against the receiver being dislodged altogether, and also prevents the rattling which might otherwise be set up by the vibration from the engines.

All the external metal work of this set is gilded or silvered to match the fittings in the cabins, and the plating is specially heavy as a precaution against corrosion. The internal parts are specially lacquered for the same reason, and all contacts are of platinum. The rosette below the instrument is provided for making connection with the line wires and the wires to the bell, induction coil and condenser. These latter are fitted together in a metal box, which is enamelled to match

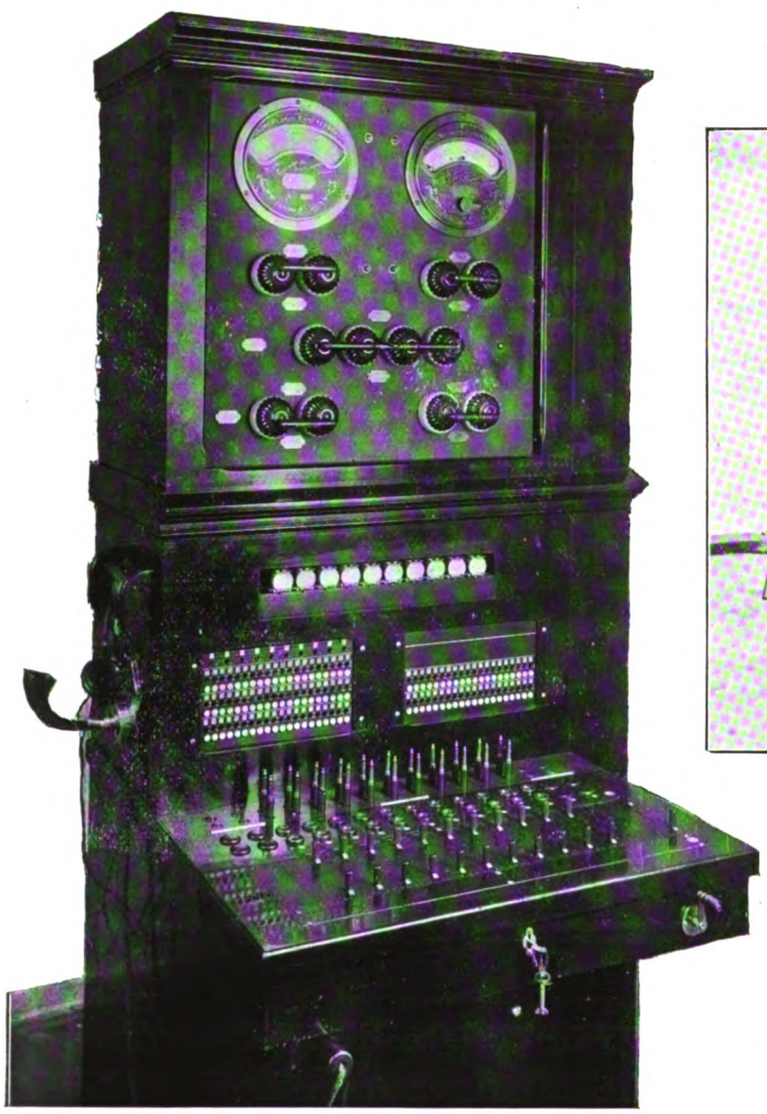

FIG. 2.—TELEPHONE SWITCHBOARD.

its surroundings, and can be fitted in any convenient position, the wiring being carried to it behind the bulkhead panelling. The connections of this instrument are shown in Fig. 4.

From the end of the main cables in the switchroom the V.I.R. wires are taken in wooden casing to a distributing frame. This is a simple construction of bar iron consisting of vertical supports fixed to the wall and standing out therefrom some 6½ in. and horizontal bars fixed across the vertical supports. The V.I.R. wires are terminated on strips of fuses mounted vertically in pairs between the horizontal bars in the upper portion of the frame. These strips usually contain 60 single fuses each, so that two adjacent strips serve 60 lines. The fuses are similar to those fitted on the main distributing frames in central battery exchanges; they carry 2½ amperes, but will operate if the current be increased beyond 3·75 amperes. Between the lower horizontal bars, heat coils and carbon arresters are fitted. These are in strips of 60 pairs each, and are of the standard central battery type; the heat coils will carry a current of 0·35 ampere but are actuated by a current of 0·5 ampere. The cables from the switchboard are terminated on these arresters. The connections between the fuses in the upper portion of the frame and the arresters in the lower portion—*i.e.*, between the line wires and the switchboard cables, are made by means of twin flame-proof cross-connecting wires run in the space between the apparatus and the wall and held in position by means of bridle rings fixed to the iron framework.

It is usual to arrange these cross-connections so that the switchboard numbers will correspond with the numbers of the cabins in which the telephones are located. The whole frame is enclosed in a glazed mahogany cabinet.

It will be seen from the foregoing that each line circuit is protected by a double pole fuse, a carbon arrester and a pair

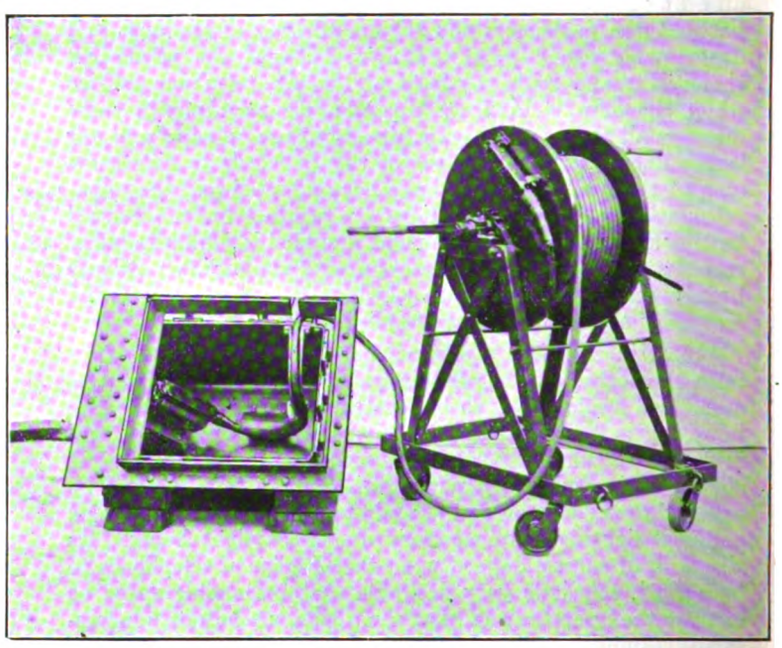

FIG. 3.—CABLE DRUM AND SUNK TERMINAL BOX.

of heat coils. The object of this protective apparatus is to prevent injury to the switchboard apparatus and wiring in the event of any of the line circuits getting in contact with the lighting or power circuits on the ship, or of any stray currents coming in over the shore lines when the ship's installation is connected up to the land system.

The heat coils afford protection against smaller currents which, while insufficient to blow the fuses are of sufficient magnitude to damage the apparatus if allowed to continue for any length of time. The heat coils do not act immediately, so that they are not affected by such currents when only of short duration.

Between the distributing frame and the switchboard, cables insulated with silk and wool and enclosed in lead sheathing are used.

A typical switchboard used on one of these installations is illustrated in Fig. 2. It is very similar in external appearance to an ordinary private branch exchange switchboard, excepting that for the sake of economy in space the switchboard controlling the battery circuits and ringing machines is fitted on the top. Lamp signalling is employed, and the lamps and line jacks are fitted in the two panels immediately in front of the operator. The 10-drop indicators above the jack panels are wired to the top strip of jacks in the left-hand panel and are used in connection with the lines to the shore system when the ship is in port. The keyshelf is equipped with connecting cords in pairs, each having two supervisory signals and the

Digitized by Google

usual listening and ringing keys. The switchboard illustrated has a capacity for 200 lines. The cables from the distributing frame enter the switchboard in a casing at the side and are connected to terminals on a connecting rack at the rear.

Current for operating the system is supplied from a battery of 13 secondary cells. In order to prevent loss of electrolyte from splashing caused by the motion of the ship, cells of the portable type are employed. It is usual to charge these direct from the ship's lighting mains, series resistance lamps being inserted to bring the voltage down to the proper figure. Duplicate batteries are provided, and one is charged while the other is discharging. This arrangement avoids any disturbance from the lighting mains being introduced on the telephone circuits.

Alternating current for ringing at 75 volts 16 ~ is supplied from dynamotors running direct off the lighting mains. These also are provided in duplicate and used alternately, change-over switches being fitted on the power board for effecting the necessary alterations in connections. It is usual to instal the ringing machines in the switchroom in a specially designed sound-proof case.

The batteries are installed as near to the switchroom as possible, in a position easy of access and permitting of efficient ventilation. The main discharge leads from the batteries are taken to the switchboard at the rear of which a slate panel carrying the distribution fuses, is fixed. Alarm type fuses, rated to carry 1½ amperes, are used.

In designing circuits for a ship's installation it is necessary in view of the unstable conditions which prevail when the ship is at sea, to give careful consideration to the type of signal employed. For example, it is obvious that an indicator of the falling shutter type would be quite unsuitable. (The self-restoring indicators on the switchboard illustrated in Fig. 2 are only used in connection with the shore lines when the ship is in port. A switch is provided to cut these off the alarm bell, when the ship is at sea.) Lamp signals are, of course, ideal, in that they are unaffected by the motion of the ship, but the knife edge type of relay by which these are usually controlled cannot be relied upon to operate satisfactorily in rough weather. The line circuits on a ship, however, are always short and the variations in their resistances are small. It is, therefore, possible, by using a 26-volt battery in place of the usual 22 volts, to work the lamps in series with the lines and dispense with line relays altogether.

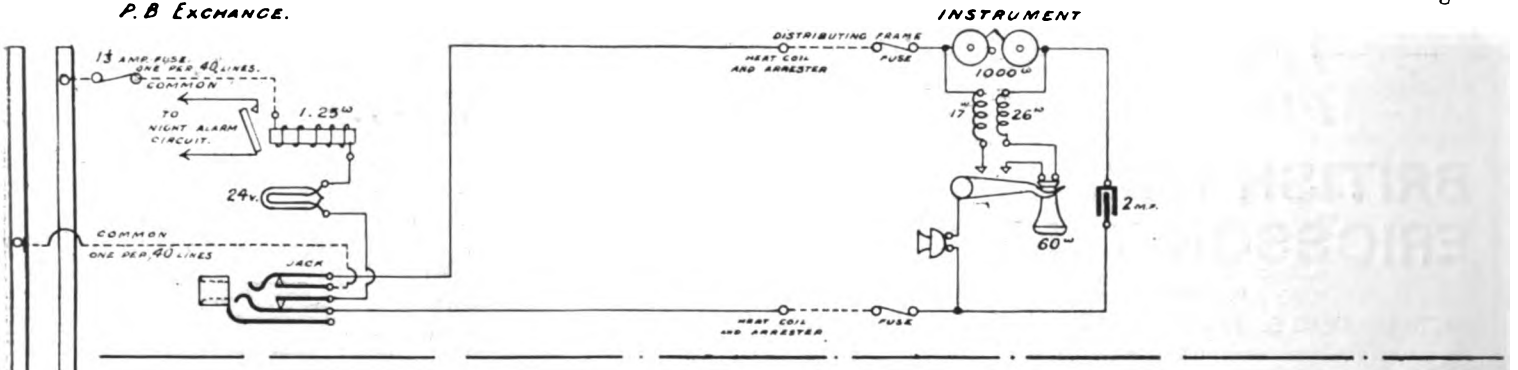

FIG. 4.—EXTENSION LINE.

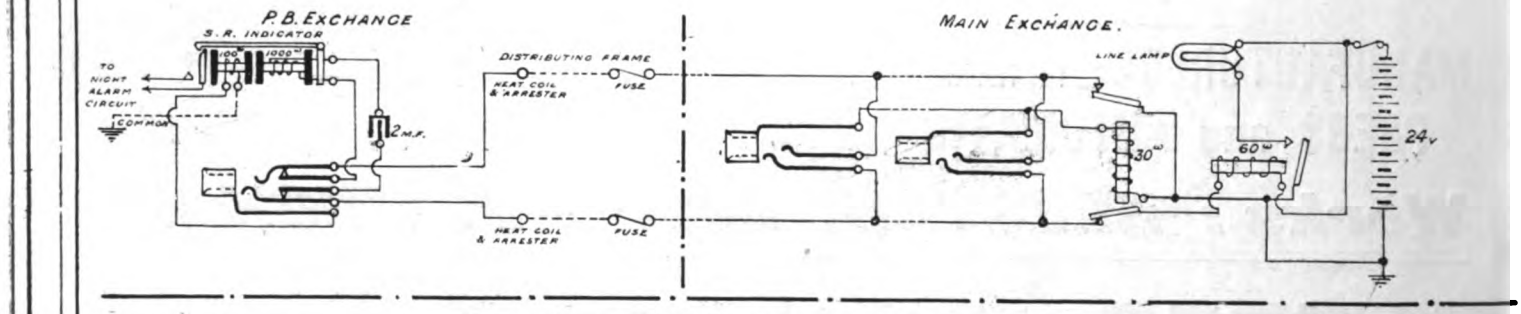

FIG. 5.—EXCHANGE LINE TO CENTRAL BATTERY EXCHANGE.

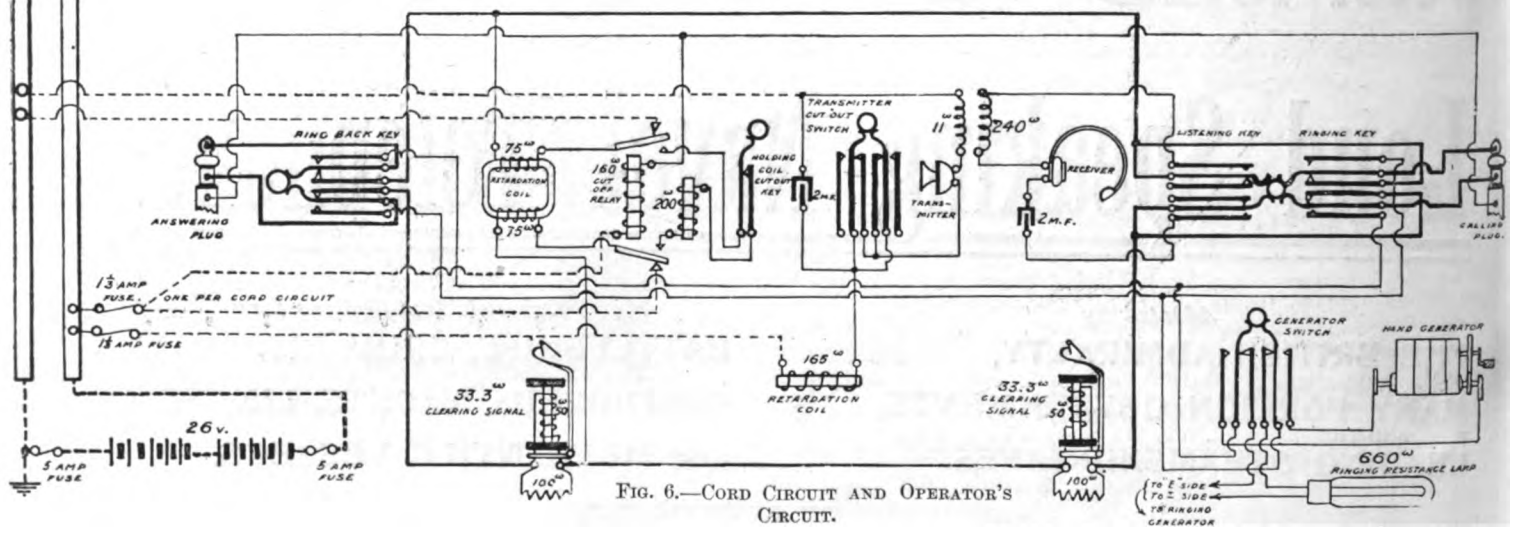

FIG. 6.—CORD CIRCUIT AND OPERATOR'S CIRCUIT.

Digitized by Google

On referring to Fig. 4, which illustrates the line circuit used, it will be seen that when the receiver is removed from the switch hook, current flows from the battery through the common night alarm relay, through the individual calling lamp and out to the A line, passing back to the B line and earth, via the 17 ohm winding of the induction coil and the transmitter. An ordinary 24-volt lamp is used, and this current is of sufficient magnitude to light it. The common night alarm relay, which is the only knife edge relay used, has a spring controlled armature and is unaffected by the motion of the ship.

The cord circuit, illustrated in Fig. 6, is identical with the circuit ordinarily used on private branch exchange switch-

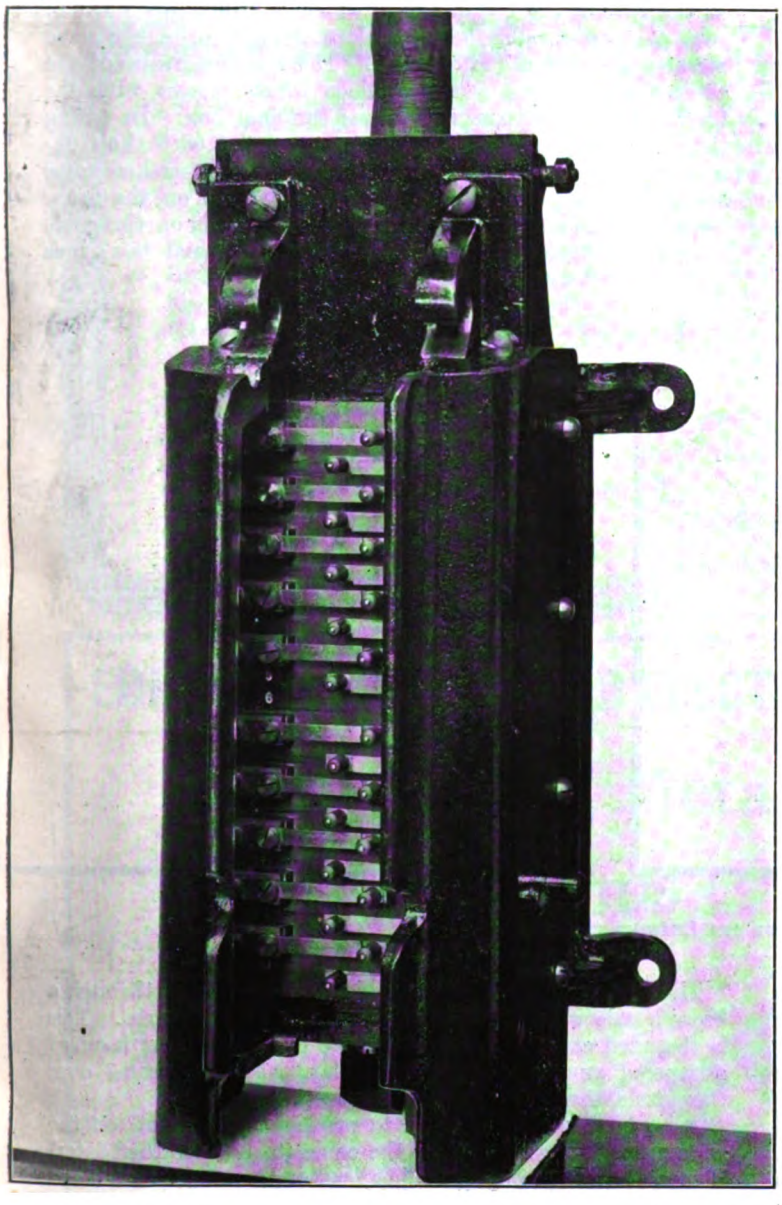

FIG. 7.—CABLE BOX WITH COVER REMOVED, SHOWING THE PLATINUM-TIPPED SPRINGS.

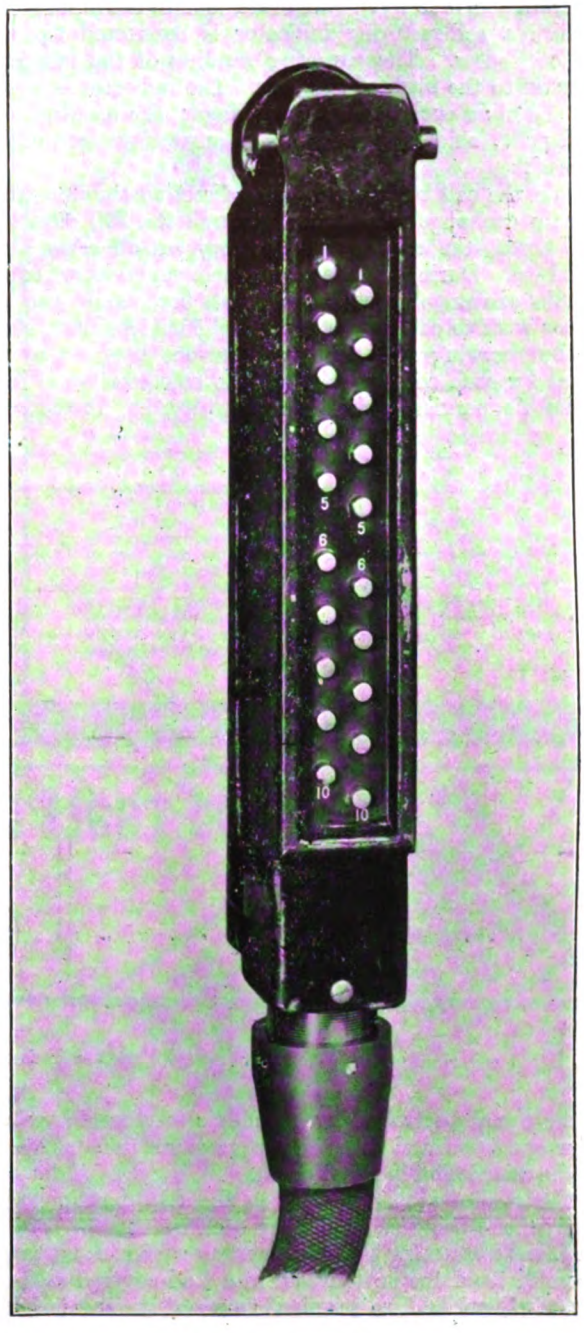

FIG. 8.—CABLE HEAD.

boards. There are two supervisory signals fitted in connection with each pair of cords. These signals are of the disc type, and are mounted vertically in the keyboard. When actuated, a white disc about the size of a sixpence is displayed; when not actuated, this disc hangs down out of sight and the aperture in the keyshelf is dark. The operating coil of the signal is wound to a resistance of 50 ohms; superimposed on this winding, and joined in parallel with it, is a non-inductive winding of 100 ohms. This provides an alternative path for the speech currents which would otherwise be considerably reduced by the impedance of the inductive winding, as the signal is connected in series with the talking circuit. Battery current for operating the transmitters and signals is fed on to each cord circuit through an individual retardation coil having two windings each of 75 ohms. The object of this coil is to prevent any overhearing which might otherwise be introduced from the common wiring between the fuses and the battery.

In order to obtain the best results in transmission when speaking over the shore lines it is necessary that the current for the transmitters be drawn from the battery at the main exchange. To effect this a cut-off relay is connected to the sleeve connections of each cord circuit. This relay is only operated when a plug is inserted into an exchange line jack, and, as will be seen from the diagram, it is arranged to disconnect the double 75 ohm retardation coil from the ship's battery and join the two windings together through a 200 ohm retardation coil. This leaves a 350 ohm bridge across the line which serves to hold the line at the main exchange.

The exchange lines are connected, as shown in Fig. 5. This diagram shows the circuits used in connection with a central

Digitized by Google

battery exchange. Should the exchange on shore be worked on the magneto system, special arrangements are made at the exchange end of the line to enable the ship's central battery circuits to work in connection with the magneto shore system. This obviates the necessity of having special circuits on the ship should the exchanges at the ports between which she plies be worked on different systems. The circuit shown at the main exchange in the diagram is the standard central battery subscribers' line circuit. On the ship the exchange line terminates on a five-point break jack to the inner contacts of which a self-restoring indicator is connected through a series condenser. The restoring winding of the indicator is connected to the bush of the jack. The indicator is operated when the main exchange operator rings; the insertion of the plug by the ship's operator when answering automatically restores it.

Should the call be in the reverse direction the line relay at the main exchange is actuated through the 350 ohm bridge joined across the cord by the battery cut-off relay already referred to. During conversation the supervisory relay at the main exchange remains operated, but should the ship's operator wish to call in the main exchange operator, she can do so by throwing the holding coil cut-out key, one of which is fitted for each cord circuit. While conversation is in progress both supervisory signals are displayed. At the conclusion the signal controlled by the ship's telephone is released, but the one associated with the exchange line remains operated until the connection is taken down.

In the case of a call confined to the ship, both signals are operative, one being controlled by each instrument.

The lines connecting the ship's system with the shore system are carried from the switchroom in a lead-covered cable such as already described, to terminal boxes of special design, one of which is fitted in a convenient position on either side of the ship. These boxes are provided in duplicate in order that the shore connections may be made with equal facility whichever way the ship is berthed.

One of these terminal boxes is illustrated in Fig. 7. This particular one has capacity for 10 circuits. The lines are connected to flat bronze springs seen in the front of the box. These springs carry at their extremities small studs tipped with platinum. They are mounted on an ebonite slab and the whole is enclosed in a gun-metal casting. Behind the slab is a space in which the connections with the line wires are made. The cable is brought into this space through a brass nozzle, which can be fitted at the top or bottom as desired. A plumber's joint is made between the lead sheathing of the cable and the brass nozzle. When the line wires are all connected up the whole of the rear space is filled solid with compound and the back screwed tightly on, red lead being used to ensure a watertight joint.

The terminal boxes are fitted in positions adjacent to port holes through which the shore cable can be brought. Each end of this cable is terminated in a cable head designed to fit in the terminal box and effect connection with the contact springs therein. The cable head illustrated in Fig. 8 is the companion one to the terminal box just described. It consists of a gun-metal casting fitted with an ebonite slab in a similar manner to the terminal box. Fixed on this slab at centres to correspond with the contact springs in the terminal box are solid gun-metal studs tipped with platinum.

The connections to the contact studs are made in a space at the rear of the ebonite slab, which is afterwards filled in with compound, and the back plate screwed on in the same manner as with the ship's box. The upper portion of the cable head is fitted with trunnions which engage with the trunnion plates on the top of the terminal box. In fitting the cable head into the box, the upper portion with the trunnions is placed in position first: the head is then pushed home and is held in position by a spring catch fixed on the lower portion of the box. When in position, the studs on the cable head press on the contact springs in the terminal box, thus completing the connections.

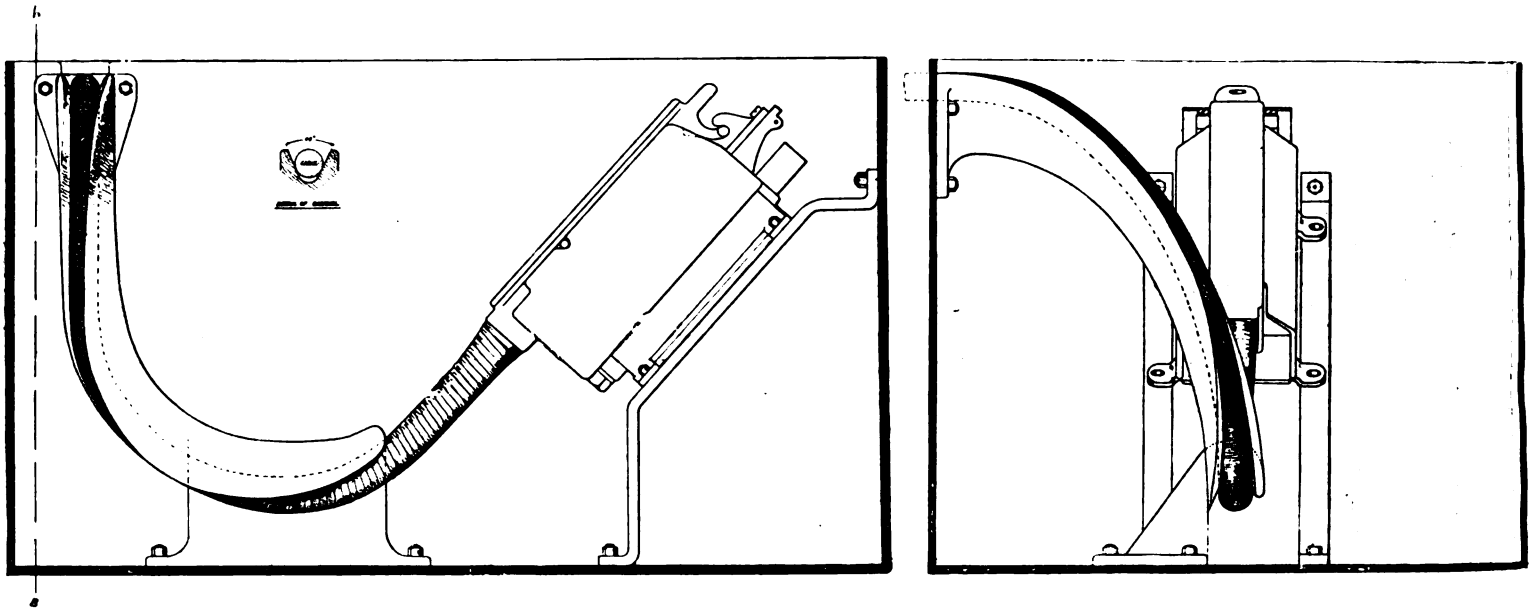

FIG. 9.—ARRANGEMENT FOR LEADING IN CABLES.

The cable enters the cable head at the lower end through a brass nozzle which is made in the form of a split grip. This is threaded externally, and after the cable has been inserted a tapered gun-metal clamping collar is screwed home over the nozzle, thus ensuring a tight grip on the cable.

As a further security, and to prevent any tension on the conductors, the steel core of the cable (to be described later) is carried through into the cable head and made off on a stout screw fixed in the casting. Before being inserted in the nozzle the end of the cable is saturated with a mixture of compound and beeswax in order to render it moisture proof, and is then served with a wrapping of waterproof tape. After the cable is inserted a helix of steel wire is fixed over the nozzle and cable for a distance of about 12 in. in order to prevent any sharp bending of the cable at the point where it enters the nozzle. The steel helix is protected by a final wrapping of waterproof tape.

Very great care has to be taken in all these operations, as it is of vital importance that the cable head and the joint should be absolutely waterproof.

The flexible cable used for completing the connection between the ship and the shore has to withstand very severe conditions, such as are seldom met with in telephone work.

Electrical Distributing Networks and Transmission Lines.

The author's aim is to provide the reader with a simple and concise account of the theoretical and practical aspects of a subject of great importance to every electrical engineer, but one which has not, perhaps, received as much attention as it deserves.

The theoretical portions of the book are sufficiently simple to appeal to those whose duty it is to maintain conducting networks in efficient working condition, and the book is characterised throughout by the greatest possible simplicity of treatment.

BY
Professor Alfred Hay, D.Sc., M.I.E.E.

LIST OF CHAPTERS
Showing the Scope of the Work.

Systems of Distribution. Comparison of Different Systems. Types of Cables. Insulation of Cables. Capacity of Self-Inductance of Conductors. Voltage Drop and Current Distribution in Network. Determination of Cross-Sections of Conductors. Insulation Resistance of Network. Potentials and Fault Resistances of Mains. Alternating-Current Networks. Localisation of Faults. Electrical Resonance and Surges. Overhead Lines. Methods of Laying Underground Mains. Joints and Joint-Boxes. Protective Devices. Exhaustive Index.

The Work contains over 100 Diagrams and Illustrations.

Demy 8vo, cloth, gilt, 10/6 *net.*

Prospectuses free from Cassell & Co., LTD., La Belle Sauvage, London, E.C.

SOME EARLY OPINIONS OF THE PRESS.

"Professor Hay's skilful and clearly-expounded treatise will accordingly be the more welcome because it breaks new ground in this field of instruction. A well systematised and lucid treatise, plentifully equipped with illustrative diagrams, it forms a valuable addition to the technical literature of electrical engineering."—*The Scotsman.*

"Professor Alfred Hay has already proved that he possesses an attribute somewhat rare among engineers—the knack of making complicated technical matter enjoyable reading. The 108 diagrams are of great assistance to the reader; they have been well selected."—*The Birmingham Post.*

"The book covers the ground very completely, beginning with systems of distribution, and passing on to deal with cables, conductors, voltage, insulation, and a large number of other topics comprised within the scope of the title, concluding with 'Protective Devices.' There are many diagrams, the book is well indexed, and the author has achieved, in dealing with his subject, what seems to be the greatest possible simplicity of treatment."—*The Glasgow Herald.*

When not in use it is kept coiled up on a portable drum, and in order that the process of coiling and uncoiling may be rapidly and easily carried out extreme flexibility is required. During the time the cable is in use a long bight swings unsupported from the ship, and it is therefore necessary that the cable should have sufficient strength to support its own weight. The insulation must be such as to suffer no deterioration from immersion in sea water.

The cable used has conductors each consisting of 23 strands of No. 36 S.W.G. tinned copper. The dielectric consists of three concentric layers of indiarubber, the first pure rubber and the second and third vulcanised rubber. Over this is a wrapping of waterproof tape. The conductors so insulated are laid up evenly in pairs with 7 in. right-hand lay. These pairs are then laid up around a stranded galvanised-steel suspender covered with ozokerite braiding. For a 10-pair cable this suspender is made up of five strands of galvanised steel, each strand consisting of seven No. 35 S.W.G. wires. It will carry, without breaking, a load of 400 lb. The whole cable so made up is wrapped with a serving of waterproof tape and finally with two flaxen braidings saturated with ozokerite. The 10 pair cable mentioned above is approximately 1 in. in diameter and weighs 6 oz. per foot.

On the landing stage or dock side, as the case may be, terminal boxes of similar design to those used on the ship, are fitted. These are installed in sunken chambers with flush covers. A sufficient number are provided to ensure one always being in reach wherever the ship is berthed. The boxes are connected in parallel and joined to the lines running away to the main exchange. In order to prevent any strains being transmitted to the cable head, a heavy casting with a curved V-shaped groove is fixed in each chamber, and the flexible cable is laid round this groove before it is taken to the terminal box.

A sketch of this arrangement is given in Fig. 9. It will be noticed that the curved groove is approximately in the form of two quadrants at right angles. The sides of the groove are inclined at an angle of 45 deg., this being the angle which provides the most effective grip. A similar device is fitted where the cable enters the ship. Fig. 3 is a photograph of one of these chambers ready for installation in the deck of a landing stage, with the cable head and flexible cable in position. It also shows the portable drum carriage on which the cable is stored when not in use, and from which the cable is paid out to the ship.

When the shipping company has a private branch exchange working in its offices at the docks the terminal boxes on the dock side can be connected to this private branch exchange instead of to the main exchange. As during the time the ship is in dock most of the calls will be between the various officials of the shipping company and the ship this is a more convenient arrangement. It does not preclude exchange calls from the ship as these can still be put through when required via the shipping company's exchange lines.

In the case of those passenger vessels on which the owners are unwilling to instal the private branch exchange system in its entirety, a system has been devised which gives all the advantages of the shore connections when the ship is in port, but is not in operation when she is at sea.

In such cases one or more telephones, preferably of the type already described, but in some instances of the magneto local battery type, are installed in certain cabins on the ship.

When the number of circuits warrants it terminal boxes of the type just described, but of smaller capacity, are fitted, and the shore connections are effected in the same way as with the larger equipments. Where only one line is required a watertight plug and socket similar to those used in electric light work is fitted on the ship, and the connection is completed by means of an armoured flexible cable. The exchange lines in these cases can either be run overhead and terminated on a pole at the dock side, or, where this method is not practicable, run underground and terminated in a watertight socket fitted in a suitable position. When the shipping company has offices close at hand it is generally found most convenient to connect the line on the switchboard at these offices and work the ship's telephone as an ordinary extension station. Where this condition does not obtain, the line is run direct to the public exchange.

When the shore exchange is worked on the central battery system no special arrangements are necessary, but where the magneto system is in use special circuits are arranged to feed battery current out to the ship's telephone so that its signalling is entirely automatic and no local batteries for speaking are required.

The writer is indebted to the Editing Committee of the "National Telephone Journal" for the use of the blocks illustrating this article.

The Telephone on Board Ship.

The conditions of working of a telephone service on board ship are so materially different from those met with in land installations that a brief description of the systems generally used will be of interest.

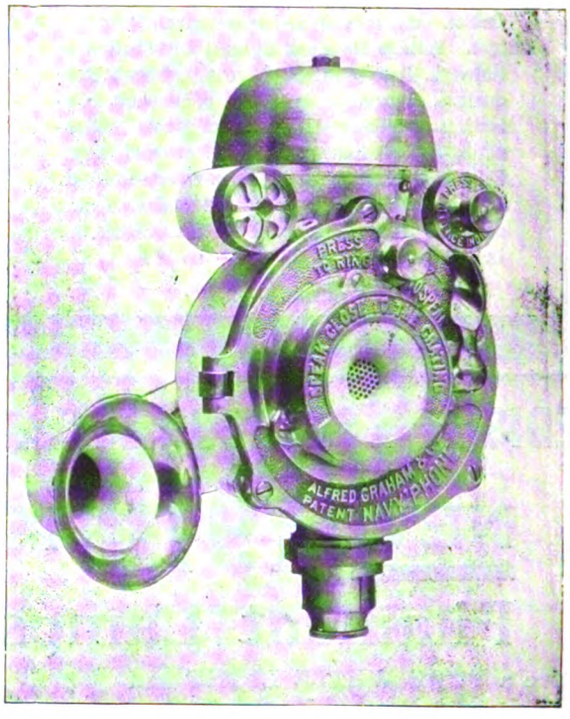

FIG. 1.—GRAHAM & CO.'S LOUD-SPEAKING TELEPHONE, AS FITTED ON THE BRIDGES.

Previous to the introduction of special types of loud-speaking apparatus the communications provided on war vessels were by the medium of voice pipes with electric bells and indicators for signalling purposes. By the employment of voice pipes of large diameter, and by carefully insulating the tubes from the hull of the ship, a certain degree of efficiency was attained; but with the increase in dimensions of ships, necessitating the use of longer lengths of piping, this method of communication was gradually superseded by the telephone. At first the application was restricted to circuits between positions some distance apart, but as the reliability and increased efficiency of the telephone apparatus have been established, the voice pipe has gradually disappeared and the use of the telephone has become general.

The requirements of the naval service are such as to call for apparatus of a totally different character from those familiar in the ordinary exchange or in domestic telephony; indeed, only the fundamental telephonic principles are in common. The characteristics of the naval telephone are particularly loud and distinct reproduction of speech, mechanical strength and

Digitized by Google

watertight construction, and with these leading features many electrical and mechanical details have been embodied, resulting in the production of apparatus of the most reliable and efficient character.

The loud-speaking naval telephones, generally referred to as "Navy 'phones," manufactured by Messrs. Alfred Graham & Co., of Crofton Park, London, are well known, being not only adopted by the British Admiralty, but by many foreign Governments and the leading steamship lines throughout the world. The types of telephones generally used are illustrated. Fig. 1 shows a loud-speaking instrument as fitted on bridges, in conning towers and many other positions; Fig. 2, shows a loud-speaking telephone with side hearing tubes and pneumatic ear-pads for use in engine rooms, boiler rooms and at stations where there is a great deal of noise. In officers' cabins a special form of hand telephone set is provided and arranged for use in combination with the various types of apparatus. An installation of telephones for a war ship is usually arranged in three groups. Firstly, a system of communication between the bridges, conning towers, engine rooms, boiler rooms and the more important positions, with instruments connected independently; and switches with indicating devices are frequently used enabling one station to communicate with several others simultaneously. The second group comprises a number of circuits similarly arranged, but in connection with the gun and fire control positions, magazines, &c.; and the third section, which links up the officers' cabins, auxiliary machinery rooms and stations of secondary importance, is connected on a central exchange system. The current for operating the telephone system is, as a rule, on the central energy plan, employing specially constructed motor-generators for the purpose of supplying current at a voltage suitable for telephonic working. The arrangement of wiring adopted on war vessels provides for the utmost protection of the cables, which are carried, as far as possible, below armour, and the feeders for each group of telephones are in many cases duplicated, and every precaution is taken to ensure the communications remaining intact during a naval action.

On board vessels of the mercantile marine, loud-speaking telephones are generally employed for communication between the navigating bridge, forecastle, docking bridge, crow's nest and engine room; also between the engine room and stokeholds. On bridges the watertight pillar instrument, shown in Fig. 3, is commonly installed. This convenient form of apparatus is also provided with a switch for communicating with several distant stations. The modern ocean liner is also provided with a cabin telephone system on intercommunication lines for the officers' quarters, and circuits from the state rooms to the respective stewards are installed for the convenience of the passengers. A form of cabin telephone, manufactured by Messrs. Graham and used extensively, is shown in Fig. 4.

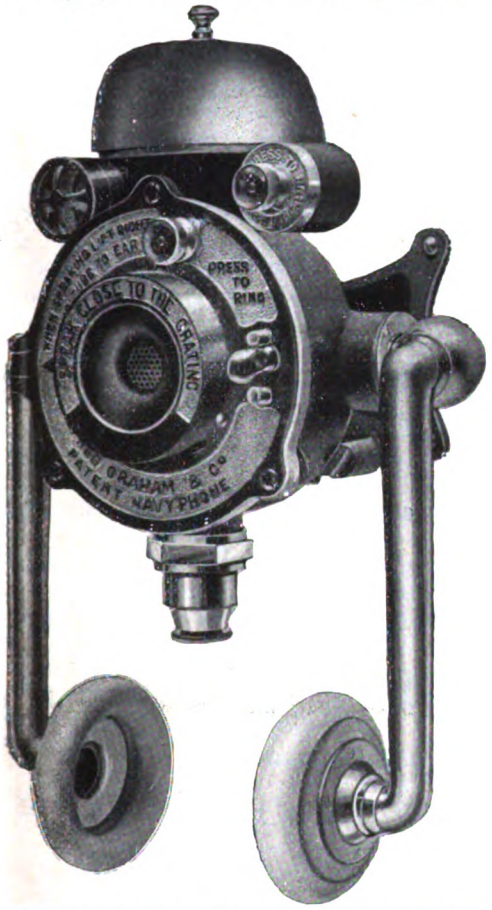

FIG. 2.—LOUD-SPEAKING TELEPHONE FOR USE IN ENGINE ROOMS, &C.

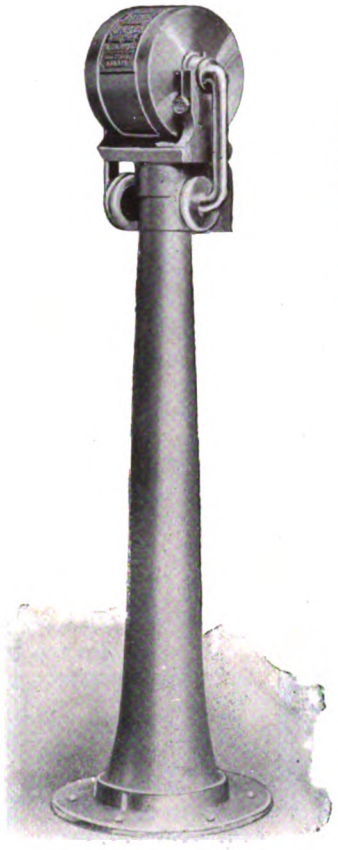

FIG. 3.—WATERTIGHT PILLAR TYPE OF TELEPHONE FOR THE BRIDGE.

FIG. 4.—CABIN TELEPHONE

Battleship Telephones.

The loud-speaking telephone has been specially developed for battleship service during the past few years, and a type of instrument is now in use which embodies the results of a large number of exhaustive experiments. For service of this kind it is essential that the instrument should be protected as much as possible, and that the system of signalling should be both simple and effective. The Ericsson Co. have completed a number of important installations of their loud-speaking telephone on several Swedish battleships, and a brief description of the system adopted will be of interest. The equipment generally consists of a nine-line switchboard on the fire-control platform, an 11-line switchboard in the conning tower and 11 telephone instruments in different parts of the ship—namely, eight for the guns and one each for the fore bridge, aft bridge and fore-and aft-bridge. An accumulator of 180 ampere-hour capacity at 4 volts completes the equipment. Fig. 1 illustrates the switchboard in use on the fire-control platform.

Digitized by Google

The whole board is enclosed in a special containing box made of zinc and brass with a watertight lid, having special tightening screws and a padlock. The switchboard is also enclosed in a metal frame which is arranged for ready removal so as to expose the connections. Within the box are a hand

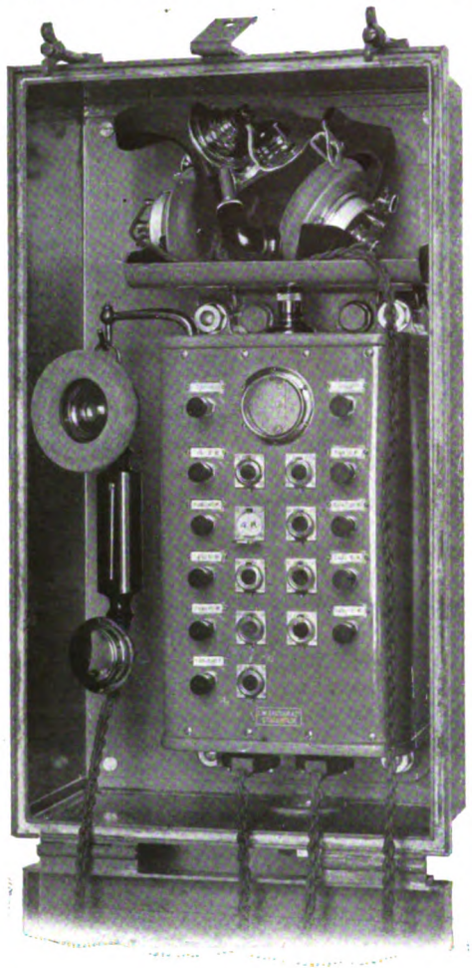

FIG. 1.—TELEPHONE SWITCHBOARD ON FIRE-CONTROL PLATFORM.

set with cord and plug, a breast transmitter with cord and plug and a headgear receiver with cap. In the illustration the latter may be seen on the shelf at the top of the box immediately above the switchboard. On the switchboard itself

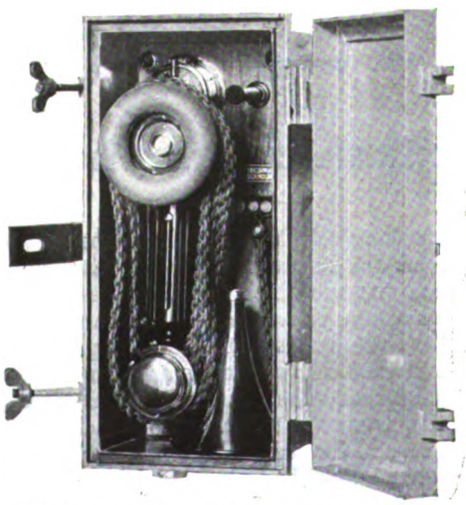

FIG. 2.—GUN TOWER TELEPHONE OUT OF USE.

are drop indicators with buzzer contacts, speaking switches, buzzer, buzzer switch, signal switch and switch-hook for hand set. At the back of the board are 32 line terminals with contact springs in groups of four terminals each. These are carefully marked to indicate the nature of each particular circuit.

The switchboard in the conning tower is similar to that illustrated for the fire-control platform, the principal point of difference being an additional number of keys and drops. There is also only a hand set for listening and speaking.

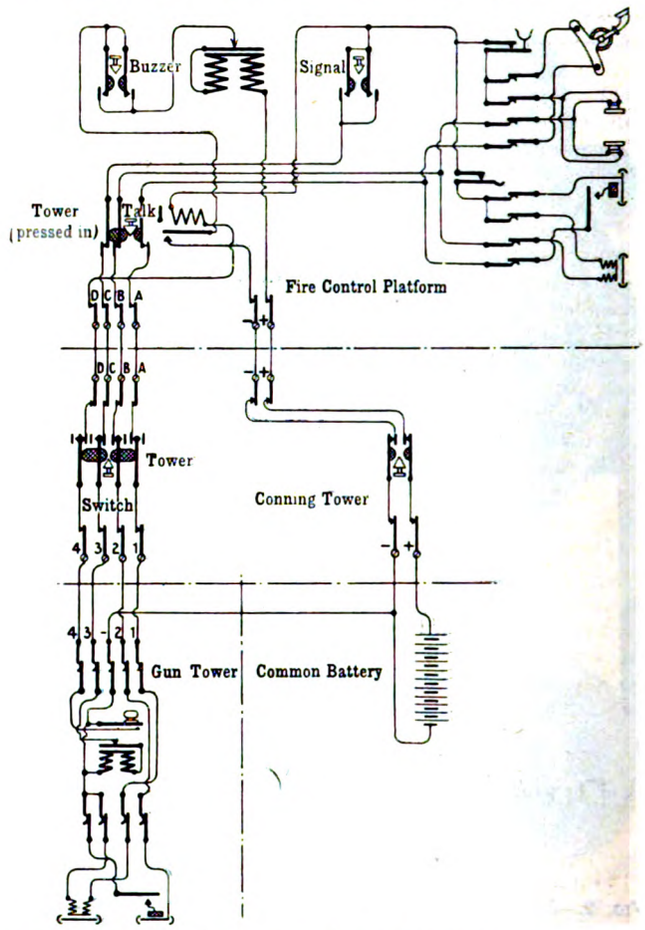

FIG. 3.—CONNECTION DIAGRAM FOR SPEAKING BETWEEN FIRE CONTROL PLATFORM AND GUN TOWERS.

The type of telephone instrument used in the gun towers is shown in Figs. 2 and 4. This comprises a hand set with cord and plug, a buzzer, a push for signalling to the conning tower

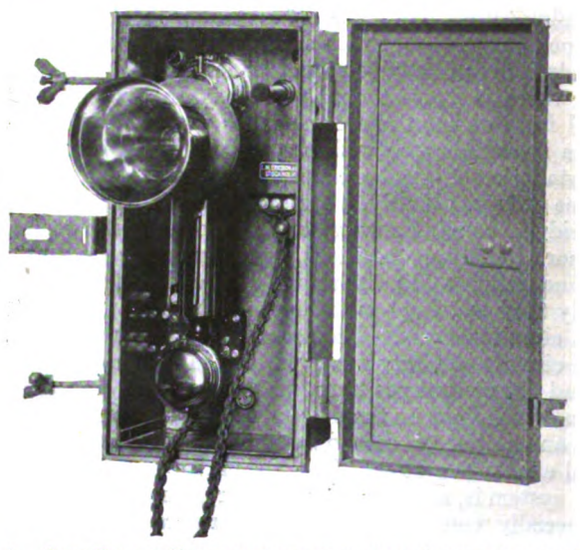

FIG. 4.—GUN TOWER TELEPHONE IN USE, WITH LOUD-SPEAKING HORN IN POSITION.

switchboard or the fire-control platform, and four-point jack and a loud speaking horn, which can be fitted into the centre of the receiver. The whole fitment is enclosed in a zinc and

Digitized by Google

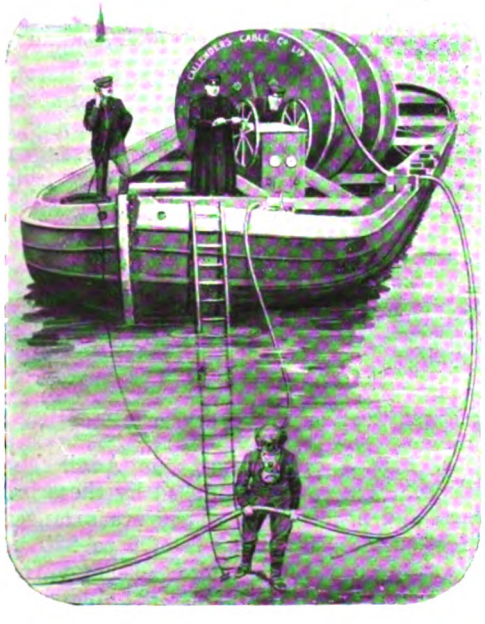
iron box, which can be made watertight by thumb screws. Fig. 2 shows the hand set and horn placed in the box when not in use, and Fig. 4 illustrates the apparatus as hung up for use.

In Fig. 3 a diagram is given of the speaking connections between the fire-control platform and the gun towers, and indicates how the various circuits are arranged for this particular communication. When calling up the gun tower from the switchboard on the control platform the speaking switch and the key of the number wanted are pressed down and a signal is given by pushing the switch marked "Signal." The answer from the gun tower is taken through the headgear receiver. When finished, the speaking key is placed in the normal position. In the gun tower itself the signal above mentioned starts a buzzer, the hand set is taken off the hook and placed in the usual position, and the listening key is pressed down. When it is only required to listen to the fire-control platform the horn is placed in the receiver and the hand set is left on the hook (*see* Fig. 4). The operations in the reverse direction—that is, the speaking between the gun tower and the fire-control platform—are equally simple. A signal is given from the gun tower and the answer is taken on the fire-control platform through the hand set. This signal is noticed on the fire-con trol platform by the fall of an indicator shutter. The buzzer circuit is closed and remains so until the shutter is raised. The speaking switch corresponding to the indicator is then pressed down and conversation commences. When finished, the speaking switch is returned to the normal position. It is also possible to communicate in both directions between the fire-control platform and the conning tower, and the conning tower can communicate with the other 11 telephone instruments when the switchboard on the fire-control platform is cut out. We are indebted to the British L. M. Ericsson Co. for the above details and illustrations.

A Diver's Electrical Life-Line.

An important part of every diver's equipment is the system of life-lines whereby communication can be effected from the bottom of the sea to the attendant boat. It is not surprising to find that the telephone has been largely used for this purpose. In the past this telephone communication with the diver has been established by means of wires laid up in the rubber air tube or by means of wires laid up in the hauling rope or life-line attached to the diver. In the former case, any fracture of the wires in the air tubes necessitated the purchase of new tubes, which was an expensive matter; in the case of the old life-lines, an extension of these, due to expansion or strain, resulted in the fracture of the telephone wires.

To combat these difficulties Callender's Cable & Construction Co. have designed a special diver's life-line, in which the telephone conductors consist of a number of small wires, giving great flexibility, and these are laid up on a central rubber core and insulated with high-class rubber. These insulated telephone conductors then form the centres of the strands of the manila life-line, with the result that such life-line can be stretched to breaking point before there is any fracture of the telephone wires. The ordinary standard rope supplied is tested to carry 1 ton.



MESSRS. CALLENDER'S CABLE & CONSTRUCTION CO.'S DIVER'S LIFE-LINE.

Marine Type Telephones.

It is not surprising to find that the telephone is just as useful on board ship as it is on land, though, owing to the much smaller space covered and the essentially different conditions in which the instruments work, it must, of course, vary in constructive details. Messrs. Gent & Co., of Leicester, have long paid a great deal of attention to this class of work, and in Fig. 1 we illustrate an instrument which is designed by them specially for ship use. It works on the central battery system with a lamp signal annunciator. By these instruments state rooms and saloons can be put into communication with the service departments of the vessel. The instruments consist of a combined transmitter and receiver of the Post Office type, contained in a polished teak case, along with the relay, press button and fixed cradle support. To call up, the button is pressed and lights a lamp signal on the exchange board. Direct the button is released the bell ceases to ring, but, on the other hand, the lamp remains alight until the plug is inserted into the jack by the exchange operator. Special features of this system as regards the exchange working are that there are no moving parts, while it is claimed that the

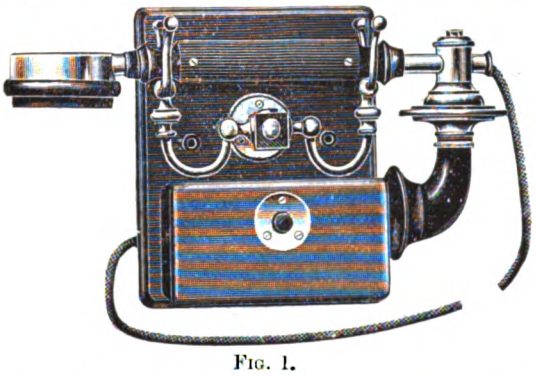


FIG. 1.

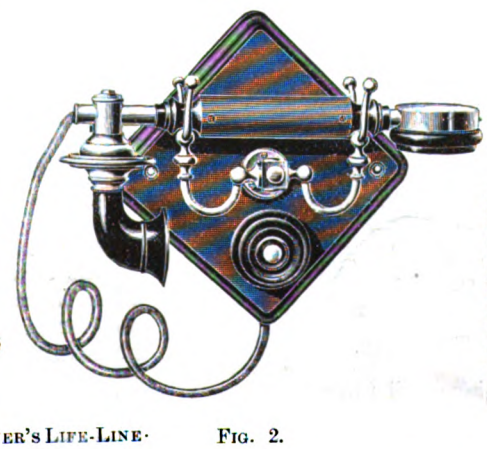

FIG. 2.

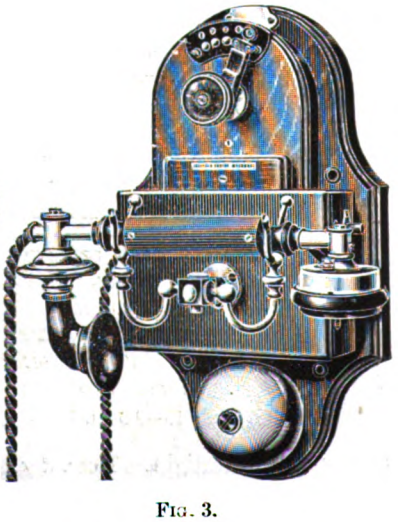

FIG. 3.

Digitized by Google

apparatus is simple and reliable. The annunciator consists of a polished solid teak case, fitted with lamp signals for working on a 4-volt circuit, together with jacks, plug and board, as well as a call bell and the operators' combined instrument.

Another system, which has been designed by Messrs. Gent & Co., is one by which the ordinary bell indicator is used as an annunciator. Separate telephones, like the one shown in Fig. 2, are placed in the various state rooms and communicate direct with the indicator. This system has been recently installed on the ss. "Eskimo," recently built by Messrs. Thos. Wilson, Sons & Co. The advantage of the instrument is that the cradle carrying the combined instrument is fixed and is not of the rocking type, while the lines can be used for bell ringing without interfering with the telephone apparatus.

Another interesting telephone apparatus made by this firm is the Parsons-Sloper *secret* intercommunication telephone, Fig. 3. With these instruments conversation can be effected by direct calling without the delay of passing through an exchange. At the same time, it is claimed, there is no cross-talk when several couples are speaking, conversation being secret. A feature of this system, which should be found as useful on board ship as on land, is that immediately on ringing up and before speaking takes place the calling operator knows if the instrument is already engaged, if the attendant at the instrument is absent, and the moment the latter comes to speak.

Telephones in watertight metal cases are made for use on bridge or other exposed positions,

Adnil Ships' Telephones and Hooters.

In designing a telephone for use on board ship care must be taken so to arrange the apparatus that it suffers the minimum of damage from the constant vibration. It must also be

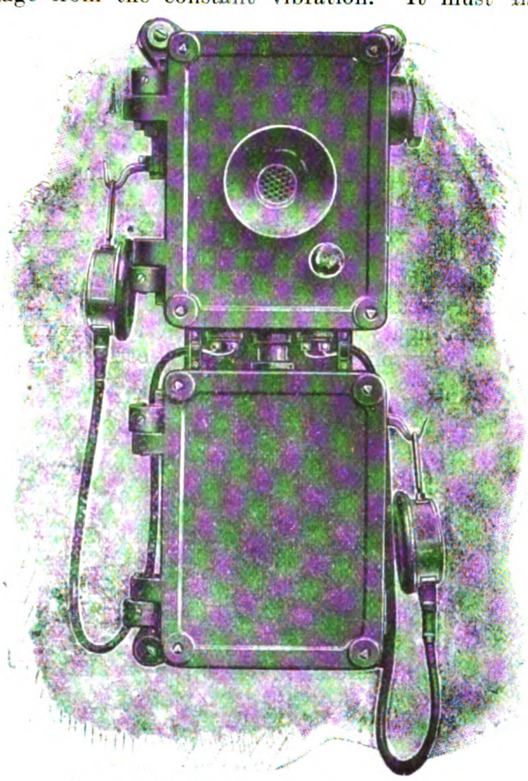

FIG. 1.—ADNIL CALLING TELEPHONE.

strong and watertight. Recently the Adnil Electric Co. have been considering these problems, with the result that they have produced an interesting instrument for telephonic purposes on board ship.

A high-frequency converter is used, consisting of a combined pole charger and transformer. This arrangement, which takes up very little room, is enclosed in the case of the calling telephone (Fig. 1) and serves the double purpose of calling generator and induction coil. A battery of two ordinary dry cells is contained in the lower part of the telephone. Pressing the calling push connects the primary side of the vibratory converter to the two-cell battery. The converter transforms this direct-current supply of about 3 volts into an alternating current of 35-40 volts which is sent out to line. The alternating current being of a very high frequency causes the receiver of the "called" instrument to emit a loud hoot or blast. This is sufficient to attract the attention of the wanted party, who then merely waits for the

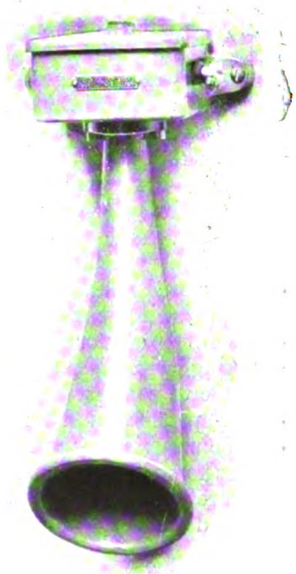

FIG. 2.—ADNIL RECEIVING TELEPHONE. FIG. 3.—ADNIL ELECTRIC HOOTER.

message. It is not necessary for him to go nearer than two or three yards from his telephone, as the words spoken into the transmitter of the "calling" telephone are loudly reproduced by the receiver of the "called" telephone, whilst any words spoken by the "called" party within a distance of a few yards of his transmitter are clearly audible in the receiver of the "calling" instrument. The "called" or "receiving" telephone shown in Fig. 2 is mounted on a cast-iron pedestal, the top aperture being the combined hooter and loud-speaking receiver, and the lower one the transmitter. In this way, loud speaking is obtained with a small current, an arrangement which possesses the advantage that "caking" or "frying" in the transmitter is avoided.

FIG. 4.—ANOTHER TYPE OF ADNIL ELECTRIC HOOTER.

The illustrations, Figs. 3 and 4 show the Adnil electric hooters for ships' use. The sound produced by these instruments is very loud and penetrating. They are arranged to work from a direct-current supply of from 3 to 220 volts. These instruments are actuated by a high-frequency vibratory generator somewhat similar to that used in the loud-speaking telephones. From a supply of anything between 24 and 220 volts, one vibratory generator is capable of actuating simultaneously as many as eight large cast-iron hooters installed in different parts of the ship. The hooters are all connected up in series with the secondary terminals of the generator, and are actuated by one press button or switch fitted in any convenient place in the ship or on the navigating bridge, and subject to the control of the officer in charge.

Ships' Telegraphs.

To take the place of the mechanically connected instruments at present in use, an electric engine-room telegraph has been placed on the market by Messrs. Siemens Bros. & Co., who claim that this apparatus embodies several advantages over the mechanical type of apparatus.

Any number of order-giving instruments can be employed, which only require the movement of a switch to change the control from one to any of the others. This can be done instantly, without regard to the relative orders appearing on the different transmitters, the engine-room instrument immediately registering the order appearing on the transmitter to which it is connected. This, of course, is not possible with the mechanically connected apparatus, and can only be effected by positive action instruments such as the one in question. The system of transmission is the same as that used in the Siemens gun fire control apparatus, which has been largely used in the service and gives every satisfaction; by this system there is only one position possible for the pointer on the engine-room instruments for each position of the handle on the bridge instrument.

The transmission is independent of the speed of movement of the transmitting handle, and can be accomplished instantly by moving the handle from one order to another. This is an advantage over the mechanical type. Moreover, the receiver pointer stops absolutely definitely on the centre of the order space on the dial, irrespective of the distance between sender and receiver, with no possibility of interference due to backlash.

The instruments on the bridge and in the conning towers have reply pointers actuated from the engine-room instruments. The position of this pointer will immediately register the last order given to the engine room, on changing the control from one instrument to another. Fig. 1 shows the instrument which is intended to be installed in the engine room.

In H.M.S. "Triumph" and "Swiftsure," as well as in many ships of the Japanese Navy, a complete system of steering telegraphs has been provided by Messrs. Evershed & Vignoles, in addition to the standard helm indicator gear described elsewhere in this issue. The system of circuits fitted in the "Swiftsure" is shown in the accompanying diagram, Fig. 2. It will be noticed that there are three hand transmitters, any one of which can work either of the receivers fitted at the hand or steam-steering stations while the receiver in the forward steering position can only be actuated by one of the two forward transmitters. The hand transmitters are usually mounted on deck pedestals, as shown in Fig. 3, illustrating an actual instrument fitted in the "Swiftsure" (then the Chilian ship "Constitucion"). They work on precisely the same principle as the automatic transmitters, differing merely in details of construction, and in the fact that the switch is moved by hand instead of automatically through the coupling rods. The transmitters can be fitted with illuminated dials, if required, and the switch for the illuminating lamp (fitted inside the instrument shown on the dial of the hand transmitter immediately below the central spindle.

Flashing Lamp for Night Signalling.

The Morse code is used at sea for night signalling, and with a suitable lamp and key a series of rapid flashes can be given. Where a ship is not wired for electric light a shutter must be used in front of an oil light, to send the flashes; but this method is slow and clumsy. The incandescent electric lamp, and especially the metal filament pattern, affords the seaman just the right type of illuminant for Morse signalling. The Wightman flashing lamp, made by Wm. McGeoch & Co., Glasgow, utilises a metal lamp for signalling and a carbon amp as a resistance and a source of light for two sunk glasses

Digitized by Google

engraved with the Morse alphabet. The metal lamp is enclosed in a lantern fitted with a circular dioptric lens. The lamp-holder is fixed to a removable brass tray in the bottom of the lantern, the tray being secured by two locking screws. A stout flexible cord connects the lamp with the Morse key, which is enclosed in a watertight box (Fig. 1). This box also provides for the insertion of a two-pin plug which serves to lead in the current from any convenient lamp-holder.

The key projects from the front of the box (Fig. 2) and it may be operated by hand or foot as required. The alphabet is illuminated by the carbon resistance lamp already mentioned, and the metal lamp in the lantern is normally always at a dull glow. When signalling, the depression of the key cuts out the carbon lamp and puts the metal lamp on full voltage. The effect is that the flashes are checked on the illuminated alphabet box by the action of the carbon resistance lamp. Further, the life of the metal lamp is increased because a small amount of current is always flowing, thereby heating the filament to a slight extent.

The entire equipment is extremely simple, as no condenser is necessary; the current consumption is also very low. The lamp has, we understand, been thoroughly tested at sea, and the signals can be distinguished to distances of 10 and 15 miles. Messrs. McGeoch have fitted upwards of 40 ships with this flashing apparatus. They are also makers of the well-known Duplex Patent Ships' Light Indicator, which has been specially designed for use with twin filament lamps, as recommended by the Board of Trade for ships' signal lamps.

Electricity Meters,

Their Construction and Management.

A THOROUGHLY PRACTICAL MANUAL FOR CENTRAL STATION ENGINEERS, DISTRIBUTING ENGINEERS AND STUDENTS,

By C. H. W. GERHARDI.

This valuable Practical Manual on the Management of Electricity Meters forms a volume in "THE ELECTRICIAN" Series. The Author has had many years' exceptional experience with Electricity Meters in connection with the Meter Department of the largest electricity supply undertaking in the Kingdom. Mr. Gerhardi's intimate acquaintance with the working of all existing meters on the market and with the details of their construction and management, is a guarantee that the book will meet the requirements of those engaged in work in which the Electricity Meter forms an essential part. In the division of the book devoted to "Testing" Mr. Gerhardi's unique experience will prove of the greatest service to supply station engineers and managers.

Very full Chapters on TESTING, and PRACTICAL HINTS to METER INSPECTORS, &c.

Wireless Telegraphy for Marine Inter-Communication.

BY W. W. BRADFIELD.
(Of Marconi's Wireless Telegraph Co., Ltd.)

Summary.—After discussing the advantages and progress of wireless telegraphy for marine purposes, the author describes the Marconi plant used on board ship in detail. This may be classified as transmitting, receiving and emergency apparatus. In conclusion, particulars are given of the number of naval and mercantile marine stations in operation in the various countries.

Wireless telegraphy is now regarded as an essential part of the equipment of large ocean-going passenger vessels. It has reached this position partly through the sensational evidence afforded by the incidents of the ss. "Republic" and the ss. "Slavonia" as to how invaluable it may prove to ships in distress, but mainly through the experience gained regarding the general usefulness of an extended means of marine communication. Numerous cases have been published from time to time showing how passengers have made use of the facilities for sending messages to and from ships on the Atlantic and other routes. In the professional circles of the mercantile marine, however, more importance is attached to the fact that wireless telegraphy has destroyed the isolation of ships at sea. Apart from the anxieties thus relieved and the risks of loss and delay thus diminished, there are many economies, in connection with embarkation and disembarkation, which may be arranged when messages can be sent to ships at any point on their course. These points need not be laboured. The fact that in Lloyd's Register each ship carrying wireless apparatus is specifically marked, and that a special section of such ships has been added, shows that wireless telegraphy has attained an assured position among shipowners and underwriters.

Recent progress to this position has been very rapid. At the beginning of 1909 (after eight years of development) there were 125 ships of the mercantile marine fitted with Marconi apparatus. At the end of 1909 the number had risen to nearly 300, and at the present time the total is about 350, and is continuing to increase at a high rate. This increase has been accompanied by a marked development in the number of land stations erected, in course of erection and under consideration. And, apart from these conspicuous developments, the use of wireless telegraphy has become practically universal in our own and other navies, having been extended from battleships and cruisers to destroyers and submarines. There is every indication that what is now standard practice in the Navy will tend to become so in the mercantile marine—that is to say, the example set by the leading passenger steamship lines will be followed by all ocean-going and Channel passenger boats and also by cargo boats. The advance will probably be cumulative, as each installation on sea or land increases the value of the service to every ship making use of it.

It is interesting at this stage to survey the progress made on the principal trade routes.

North Atlantic.—This is the route where wireless telegraphy has been most developed, owing in a large measure to the chain of shore stations established by the Marconi Company in Great Britain, Canada and the United States. All the leading vessels plying between European ports and North America are equipped, the total being 130, belonging to British, French, German, Dutch, Italian, United States and Greek companies. Under an agreement made last year, the shore stations of the Marconi Company in Great Britain passed into the hands of the Post Office, with the exception of the high-power stations at Poldhu and Clifden, the former being used for the transmission of news to Atlantic liners and the latter for the trans-Atlantic service.

South Atlantic.—The great route between Europe and South America comes next in order of importance. Eighty-five ships are already equipped, owned by the Royal Mail Steam Packet Co., the Koninklijke Lloyd, and the principal Italian companies. With the completion of the long-range station at Coltano and the erection of shore stations in Brazil and the Argentine, further developments in this important trade route are certain to take place. Coast stations have been erected at Guaratiba, Ponta Negra, Ilha Raza and Rio de

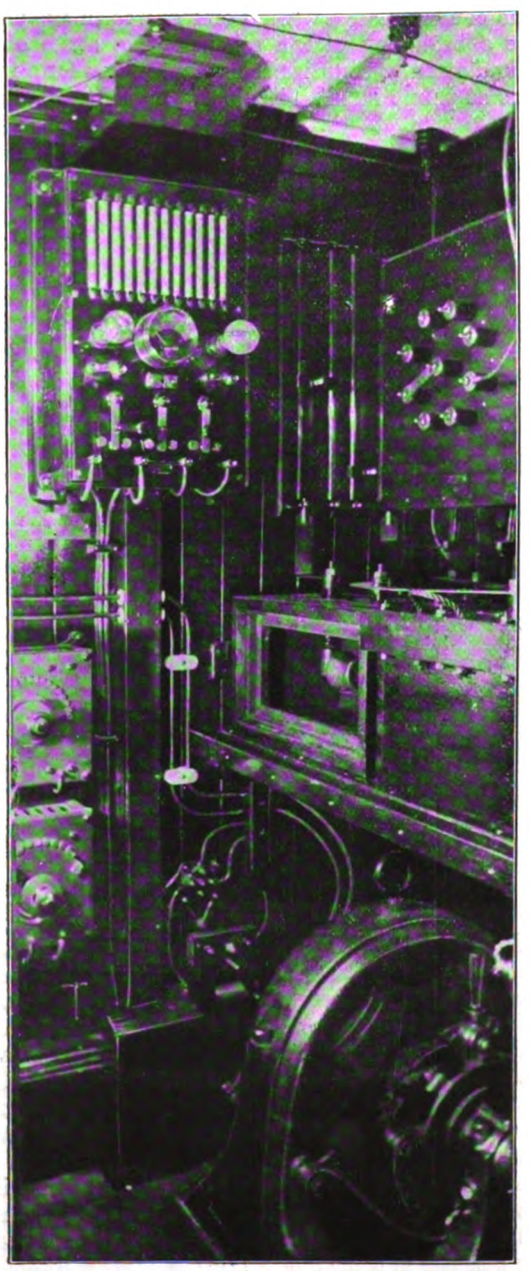

FIG. 1.—TRANSMITTING CABIN ON SS. "LUSITANIA."

Digitized by Google

Janeiro, in Brazil; at Punta del Este, in Uruguay; and at Bernal, in Argentina, on the River Plate.

South African.—Substantial progress has been made on this route. The Aberdeen Direct Line (Rennie Brothers) has used wireless telegraphy for some time, and the Union Castle has made a start with the ss. "Balmoral Castle." A Marconi station is in course of erection at Durban, and when it is ready the White Star liners in the New Zealand service will be fitted. The White Star Australian boats are all being equipped. Further advances will follow the erection of shore stations by the Cape Government.

Eastern Route.—The potentialities of wireless telegraph developments on the great route through the Mediterranean to India, China and Australasia are enormous. Eleven P. & O. vessels and 16 Dutch vessels trading to Java are already fitted with Marconi apparatus. The ss. "Otranto," of the Orient Steam Navigation Co., is the first ship of this line to carry an equipment, and it is intended to fit the entire fleet during the coming season. The Commonwealth Government has made a beginning with a scheme for a series of shore stations, and arrangements are being undertaken for a number of stations at points intermediate between Australia and this country.

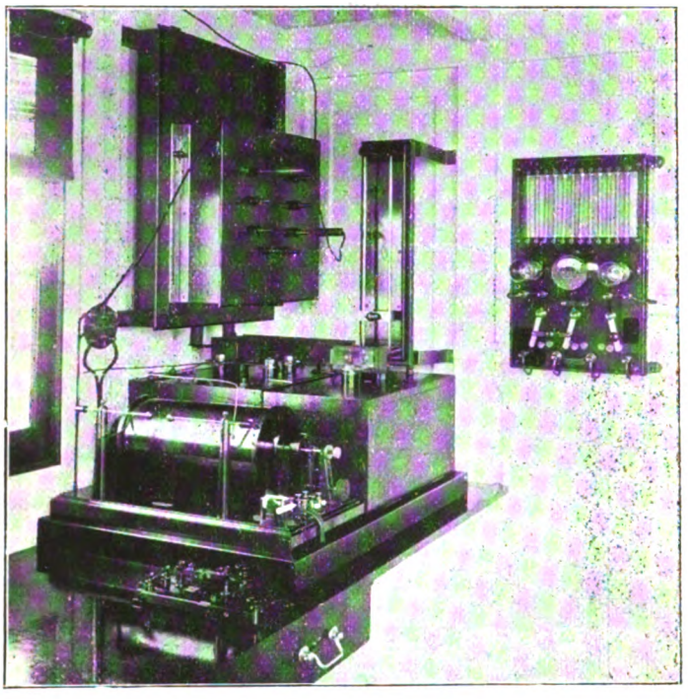

FIG. 2.—EQUIPMENT ON SS. "ONWARD."

The development of regular communication between an increasing number of moving stations has necessitated not only a carefully devised organisation, but a uniform method of working. This, in turn, has necessitated a practical standardisation of apparatus. At the same time, the demand for absolute reliability in the hands of ordinary operators has led to the evolution of a type of apparatus which is free from complications and is constructed to work continuously without derangement. From the accompanying illustrations it will be observed that most of the working parts are contained in solid boxes, which protect them from damage and limit the responsibilities of the operator to superficial adjustments and the ordinary business of receiving and transmitting messages. The advance in electrical design has been accompanied by a close attention to mechanical detail, with the result that failure on the part of the apparatus itself is practically unknown.

WIRELESS APPARATUS.

These points will emerge more clearly from the following detailed description of the standard 1½ kw. Marconi set usually installed on ships. The everyday transmitting range of these sets varies from 70 to 300 nautical miles, according to the height, length and shape of the aerial, these factors being determined in turn by the dimensions of the ship; while the night range may be anything from two to three times the day range, according to the conditions of the atmosphere. They are designed to produce waves of 300 and 600 metres, with a simple change-over; and the receiving apparatus provides for tuned reception of all waves between 100 and 2,500 metres, the range of reception depending upon the aerial available and the power of the corresponding station.

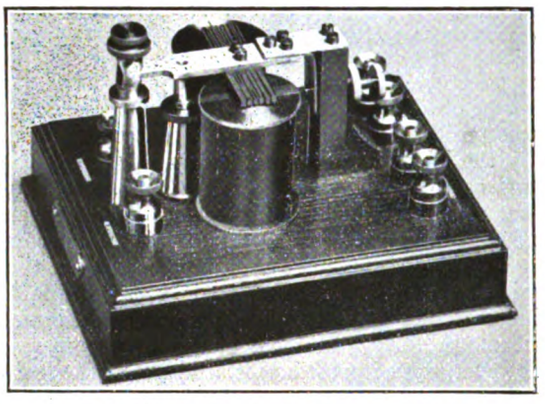

FIG. 3.—GRAY MAGNETIC RELAY KEY.

Current (D.C.) is obtained from the ship's mains and led to a rotary converter, which supplies alternating current to the main terminals of a switchboard. (Emergency apparatus is always installed for working off a battery of accumulators in the event of the ship's supply failing—as was the case with the "Republic" after the collision.) The converter is designed to give an output of 1½ kw., and to take current from the direct-current supply available. It has four poles, and runs at 1,500-1,800 revs. per min., with a frequency of 50 to 60 periods. Variation in speed is obtained by the field regulator.

Transmitting Apparatus.—The low-frequency circuits consist of an adjustable inductance, the coils of a magnetic relay

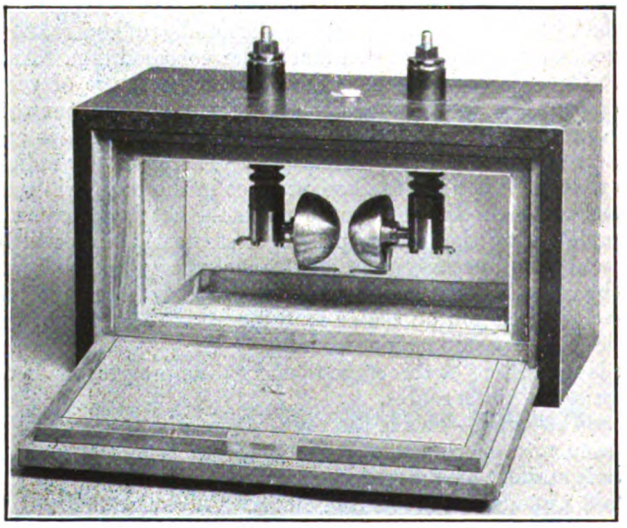

FIG. 4.—SPARK DISCHARGER IN BOX.

key, and the primary of a potential transformer connected in series and then to the two-line terminals of the switchboard. This circuit is opened and closed by the main switch, and operated by a Morse key actuating electrically the relay key. (Figs. 1, 2 and 3.)

The secondary of the potential transformer connects at the discharger through two air core protecting chokes with the primary high-frequency circuit. The transmitting condenser is connected to one side of the discharger and primary high

Digitized by Google

frequency tuning inductance to the other side. Between them is connected the primary of an oscillation transformer or transmitting jigger. The secondary of this transformer is connected at one end to the aerial and at the other to the top plate of a micrometer spark-gap, the bottom plate being "earthed" by connection with the iron shell of the ship. A tuning lamp and choke are put in shunt with a short length of the wire connecting the jigger secondary to the micrometer spark-gap. The transmitting set is completed by an aerial tuning condenser, which is used only when it is necessary to decrease the natural period of the aerial circuit in the transmission of the 300-metre wave.

Receiving Apparatus.—The connection of the receiving apparatus with the aerial circuit is made at the top plate of the first micrometre spark-gap. From here a lead is taken to the

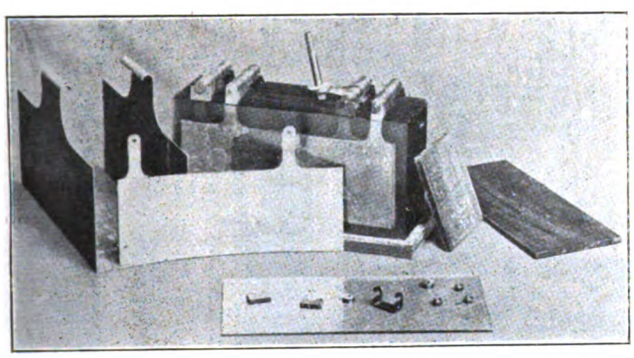

FIG. 5.—INDEPENDENT GLASS PLATE CONDENSER PARTS.

aerial terminal of the tuner, the earth terminal of the tuner being connected to the bottom plate of the micrometer spark-gap.

The primary terminals of a magnetic detector are connected to the tuner, and the secondary terminals to a telephone and shunting telephone condenser.

Emergency Apparatus.—In this a battery of accumulators, charged by the ship's dynamo, provides current to work an induction coil. A separate key is used for operating; or, in the cases where a special change-over switch is provided, one key is used for operating both circuits.

Spark Discharger.—The mushroom-shaped electrodes, which are of cast iron, are mounted on ebonite insulated brass rods and placed in a teak silence box lined with asbestos and lead. (Fig. 4.) Lime is placed in a removable zinc tray to absorb the acid produced by the spark. The gap is adjusted by turning the electrodes on their threaded brass supports. A protective point spark-gap shunting the main gap is set for a fixed gap to protect the condensers against excessive voltage.

Half-plate Condenser.—This is in two parts, each with 36

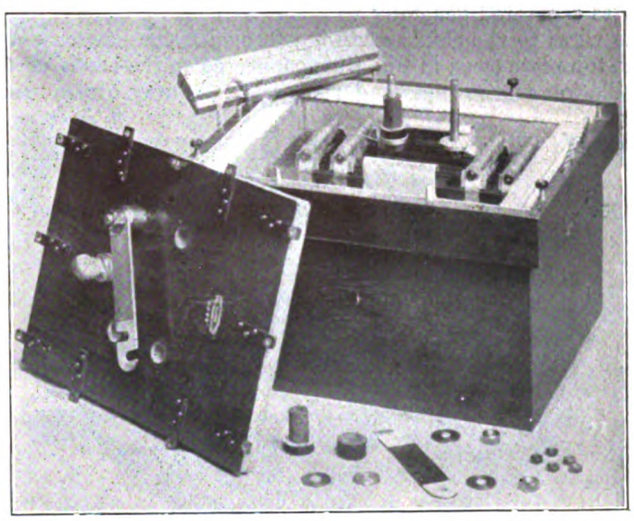

FIG. 6.—INDEPENDENT GLASS PLATE CONDENSER IN CASE, PARTIALLY ASSEMBLED.

glass plates interspaced with 35 sheets of zinc. Ninety-four plates are active, the others being guard plates. They are $\frac{1}{16}$ in. thick, and are individually tested to 27,000 volts. The container is filled with high-flash insulating oil. For the short wave the two parts of the condenser are connected in series, and have a capacity of about 0·016 mfd. With the long wave, in parallel, the capacity is about 0·065 mfd. The condenser is seen in Figs. 5 and 6.

Variable Coupling Oscillation Transformer or Transmitting Jigger.—The primary and secondary windings are provided respectively by two coils of heavily insulated wire, the former

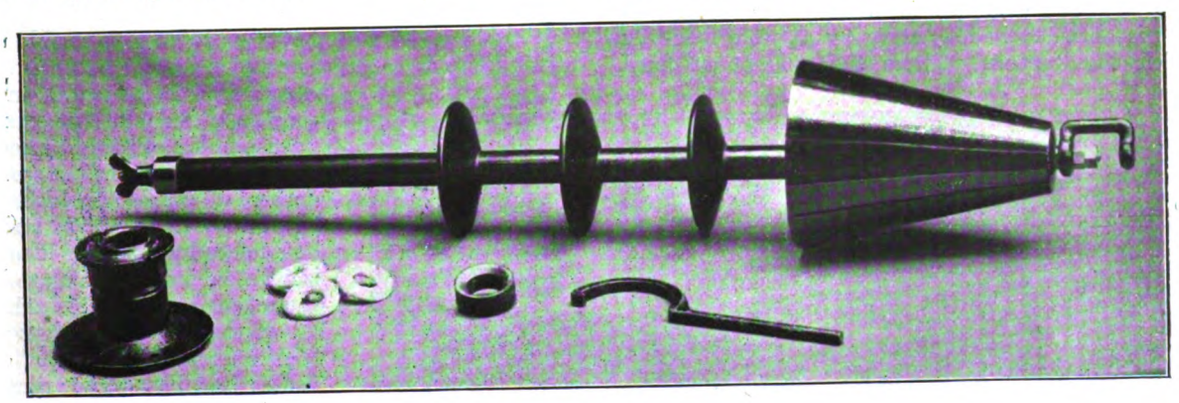

FIG. 7.—BRADFIELD INSULATOR.

The aerial lead-in is connected, by means of a flexible wire, to a socket on an insulating pillar, which in turn is connected to one end of the induction coil secondary, the other end of which is connected to earth. When receiving, the aerial terminal of the tuner is connected by a flexible and plug to the socket on the insulating pillar.

DETAILS OF APPARATUS.

A full description of the details of the apparatus would occupy too much space, but the following particulars include the salient points about the more important parts of the transmitter

of one turn and the latter of seven turns. It is at this point that the wave-generating and wave-radiating circui s are coupled together. For the purpose of adjusting the coupling between the circuits the secondary is made to slide laterally over the primary. On each oscillation transformer is a scale which gives approximately the percentage coupling between the two windings.

Aerial Tuning Inductance.—Tappings are made at various points on 20 turns of insulated wire and brought to eight insulated terminals in front of the box.

Aerial Lead-in.—This is a $\frac{1}{2}$ in. metal rod in a long ebonite

Digitized by Google

tube, which passes through a cast-iron gland fixed on the roof of the cabin. A zinc cone is fitted to the external end of the rod to ensure that a considerable length of the ebonite will remain dry in all circumstances. A shackle head on the cone takes the strain of the aerial, and prevents the connection being worked loose by the vibration of the aerial wire. Three ebonite discs spaced along the external part of the ebonite tube prevent surface sparking in event of heavy weather causing the insulator to be wet with salt spray. (Fig. 7.)

Earth Arrester Terminal.—This consists of two round brass plates separated generally to about 0·01 in. by discs of mica. The wires to the ship's earth connect with the bottom plate. The top plate (seen in Fig. 8) is connected to the earth of the oscillation transformer and the aerial terminal of the tuner.

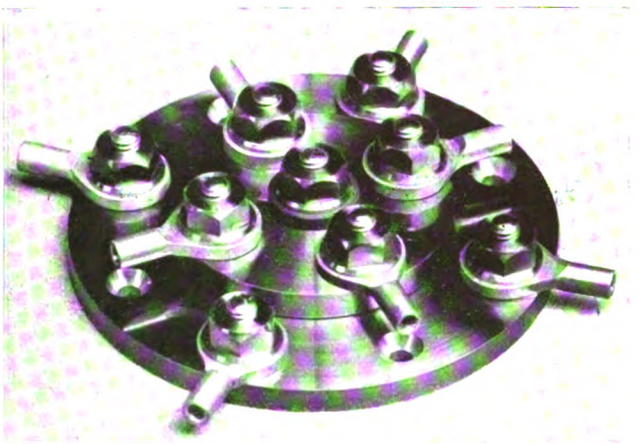

FIG. 8.—EARTH ARRESTER TERMINAL.

When transmitting, the top plate sparks on to the bottom plate and connects direct to earth. When receiving, the top plate remains insulated and the aerial oscillations find their way to earth through the tuner. The terminal, while serving as an automatic switch, also provides protection for the aerial against lightning.

Multiple Tuner.—A means of tuning to the incoming signals of one given wave-length, and eliminating the signals of all other wave-lengths, is provided by three inductively coupled adjustable circuits, the first connected to the aerial and the third to the magnetic detector. The full range of 100 to 2,500 metres is obtained in four steps by a triple four-way switch, which simultaneously alters the amount of fixed inductance and capacity in each circuit. Accurate tuning is obtained by an adjustable tuning inductance and variable condenser in all circuits. Injury to the instrument when transmitting is prevented by a micrometer spark-gap, which automatically shunts the aerial terminal to earth.

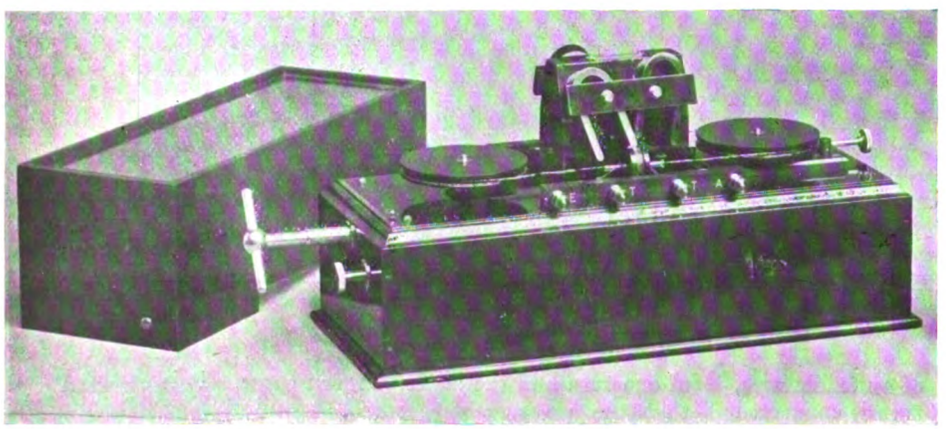

FIG. 9.—MAGNETIC DETECTOR.

Magnetic Detector.—This instrument has been described so often that particulars would be superfluous. It may be mentioned that for the greatest intensity of signals the two permanent magnets should be placed with like poles together over the coils. This arrangement, however, introduces a low noise in the telephone termed " breathing." If the magnets are placed with unlike poles together, one of them well down on the coils and the other with its inside limb at a certain distance up the inside limb of the first magnet (the correct position being found by test), the " breathing " becomes negligible, at the expense of a very slight decrease in the intensity of the signals. The detector is seen in Fig. 9.

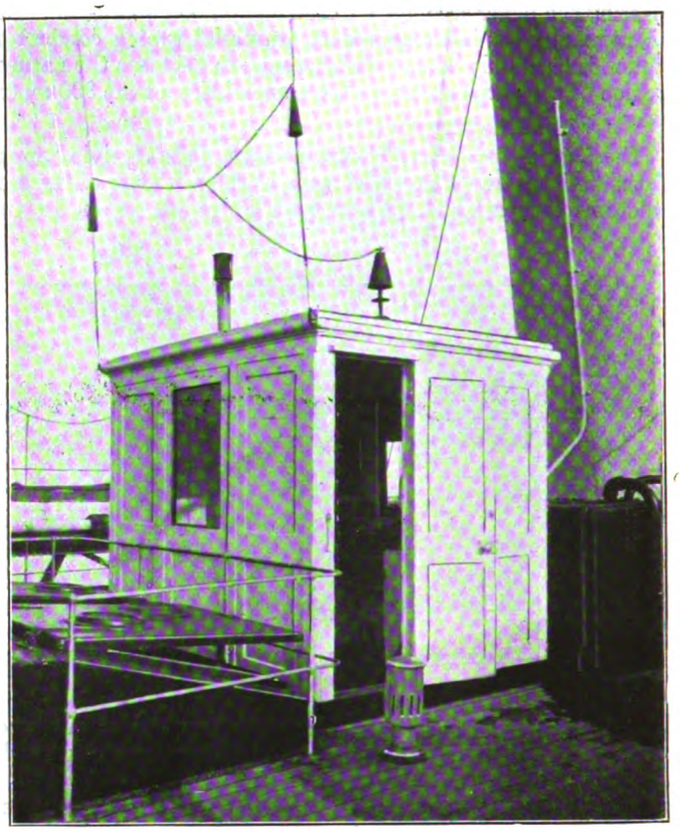

FIG. 10.—WIRELESS CABIN ON SS. " ONWARD."

Wavemeter.—A wavemeter is provided to enable the transmitting circuit to be correctly adjusted to the international waves of 300 and 600 metres. It consists of an inductance coil with a fixed number of turns connected to an adjustable condenser. Across the condenser is shunted a high resistance asymmetrical crystal in series with a double-head telephone. The condenser is adjusted until signals are loudest in the telephone. A table affixed to the lid of the wavemeter gives the wave-length corresponding to each condenser reading. The range of the standard apparatus is from 200 to 800 metres.

Aerials and Aerial Insulators.—Bare silicon bronze wires are used for the aerials. The overall dimensions depend on the design of the ship. In shape the aerials are either a twin L or a twin T, the spacing between the twins being 12 ft. A 12 ft. 6 in. ash spreader usually supports the aerial at each end. The spreader has two bands, each with two lugs, one taking an aerial strain insulator and the other one leg of the spreader bridle, the bight of the bridle being in turn made fast to the halyard. The strain insulator commonly in use for

Digitized by Google

short aerials is 3 ft. long and circular in section, composed of Palmer cord encased in rubber and vulcanised. It is designed for a working load of 10 cwt. and a breaking load of 30 cwt. Long aerials are supported on larger insulators in the same manner. Each insulator is covered with a special insulating

WIRELESS TELEGRAPHY IN OPERATION.

It is practically impossible to give any idea of the extent to which wireless transmission is in operation, not only on passenger vessels, but in the case of cargo boats, cable-laying vessels, lightships, private yachts and other classes of vessel apart from the navies of the world. But the following list of the communications effected day by day in the case of a typical Atlantic vessel will indicate the importance of wireless telegraphy in one of its most conspicuous phases—a trans-Atlantic voyage on a large liner :—

Tuesday, May 3rd.

9.40 a.m.	Ship docked New York, station closed.	

It may be of interest to observe that of all the communications effected as above noted, in only one case, namely, that the Scheveningen (Holland) was the corresponding station not fitted with Marconi apparatus.

The use of wireless telegraphy on cable-laying vessels, yachts and other special classes of ship is increasing. At present the following cable-laying boats and private yachts have been equipped by the Marconi Company :—

PRIVATE YACHTS.

s.y. "Iolanda."	s.y. "Cassandra."	s.y. "Atalanta"
s.y. "Lysistrata."	s.y. "Niagara."	s.y. "Florence."

CABLE SHIPS.

c.s. "Mackay Bennett."	c.s. "Colonia."	c.s. "Cambria."
	c.s. "Buccaneer."	

The conditions under which cable-laying vessels have to work make the value of wireless telegraphy very conspicuous in their case. Repairs have to be carried out at long distances from shore, and as a rule the vessels have to return to port before instructions regarding subsequent work can reach them, with the result that expensive delays are frequently incurred. An example of the service which wireless telegraphy may render is supplied by the following extract (modified in details of wording) from the log of a cable-laying ship :—

On one occasion we were repairing a cable some 180 miles from the west coast of England, and required further information about electrical tests from the shore. A message was sent and received by another steamer equipped with a Marconi wireless installation and relayed by her on to England, the result being that in less than an hour we had a reply from London giving the desired information, and enabling the vessel to proceed with her cable-laying operations without delay.

Considering that the inquiry was relayed, and necessitated a careful answer from headquarters, also relayed, the time occupied was remarkably short. On another occasion, when the vessel was on her way home from the completion of a repair off Ireland, a wireless message was received ordering her to the coast of France for another repair, thus saving a useless voyage back to London.

The standard equipment for marine work is either the 1½ kw. set just described or a 5 kw. set, where a disc machine takes the place of the spark discharger. Both sets are capable of exceeding their guaranteed limits. For instance, in the case of certain destroyers, the guaranteed range of transmission was 60 miles, but nearly all of them exceeded 80 miles on their tests. In the case of a larger vessel, the guaranteed range was 100 miles and the realised range was 185 miles. Another war ship fitted with a 5 kw. installation exceeded her guaranteed range of 250 miles by more than 100 miles.

As already indicated, the number of wireless installations on shore and on ships is increasing so rapidly that up-to-date official statistics covering the whole of the world are impossible to obtain. The following figures, taken from the Bulletins of the International Telegraph Bureau, will give some notion of the extent of the business, but they must not be taken as complete, since certain countries have not ratified the Convention or made complete returns.

Country.	Number of naval ship stations.	No. of stations in the mercantile marine.
Great Britain	176	113
Germany	93	67
France	140	10

The Helsby Wireless System

The rapid growth of commerce and the provision of improved means of transit has rendered a corresponding extension of our methods of intercommunication a necessity. It has long been realised that, if a system of telegraphy or telephony which does not require the installation of conducting wires or cables were discovered, the field of operation of electrical communication would be vastly extended. It is interesting to note that while the development of our postal telegraph system has always been in the hands of engineers who were previously experts in intercommunication, wireless telegraphy has developed chiefly from the adaptation of results obtained in scientific laboratories, and under the guidance of those who are scientific electricians first and telegraphists—if at all—afterwards. A perusal of recent patents, or an inspection of some modern wireless telegraph stations, shows in a remarkable manner how this "history" has affected the methods adopted, and particularly the form of the apparatus.

While we have the highest appreciation of recent research work, which has so greatly extended our knowledge of electric oscillations, certain engineers maintain that inasmuch as radio-telegraphy is a branch of engineering, and that all engineering design is necessarily a matter of compromise between complexity of construction—with perhaps a higher measurable efficiency in expert hands—as compared with simplicity and reliability on the other, that a higher overall efficiency as regards traffic can be obtained by designing the apparatus to suit the skill of the average wireless operator rather than add refinements of detail and complexity which the operator has neither time nor the necessary knowledge to use effectively.

These facts have been carefully considered in the design of the apparatus used in the Helsby system. It is throughout "telegraph" apparatus adapted both to the requirements and the capacity of the operator into whose charge it will be placed.

The general principles underlying all the various systems of wireless telegraphy are identical, however much they may be disguised by the introduction of subsidiary instruments, and consist in the means for producing, at will, electrical oscillations of great energy in an elevated conductor and means of detecting feeble oscillations set up in the same conductor when a message is being received. Hence the apparatus may be rationally divided into two main groups—transmitting apparatus and receiving apparatus—but what is of equally great importance is the provision of suitable controlling devices by which the station is instantly convertible from one function to the other.

Novelty of design and extreme practicability of the instruments fulfilling each of these functions are claimed to be the distinguishing features of the Helsby system, and they combine to confer upon it a very high efficiency. In common with the majority of electric wave systems, the oscillations used are produced by the sudden discharge of "condensers." The Leyden jar still used in many systems has, the company feel, several disadvantages, *i.e.*, great bulk for given capacity, uncertain contact with tinfoil electrodes, perforation of dielectric, loss of energy by brush discharge, which—together with its fragile properties—make this form of condenser most unsuitable.

The condensers used are built up of flat plates—giving economy of space—and conductors of copper foil to which a permanent and electrically perfect joint can be made. The dielectric consists of specially selected glass plates showing extremely small dielectric losses, the whole being clamped together in a form similar to that adopted in accumulator practice, and immersed in a special insulating compound, which entirely prevents brush losses. Perforation of the plates is rendered impossible by the provision of relief gaps which act as electrical safety valves.

These condensers are charged from a high-tension transformer of improved design. A patent alloy is used in place of iron in the core, and magnetic material is distributed so as to minimise losses due to eddy currents and to prevent hysteresis. The primary windings are so disposed as to allow of the standard instrument being used in connection with circuits at various voltages and frequencies. The secondary windings are so arranged as to obtain the highest insulation and efficiency with minimum resistance and weight of wire. Connection between the transformer and oscillation circuits is effected by "protection plugs," which prevent oscillations passing into the secondary winding. In the portable wireless outfit the above improvements are embodied in an induction coil which is provided with a special form of interrupter, giving a high rate of interruptions with great regularity of action.

The condensers discharge through the primary of an oscillation transformer and discharge gap of original design. Two forms of discharge gap are used by the Helsby Company, and both show a very marked improvement on existing types. The first is a multiple gap, and is practically silent in action. The distressing noise so characteristic of certain systems, and risk of messages being overheard by unauthorised persons, is entirely overcome. The gap is also rendered free from the deleterious effects of moisture and acid vapours. The second spark gap used by this company is of novel design, and confers upon the received signals a clear musical note.

The oscillation transformers consist of two flat spirals, each adjustable as to inductance; mutual induction between them being also adjustable to meet the requirements of the government regulations. Curves are supplied with the apparatus giving the adjustments for the two commercial wave-lengths of 300 and 600 metres. The receiving and controlling devices are contained in one piece of apparatus, which is arranged in an extremely compact form. It comprises an ordinary single current Morse transmitting key, which, in addition to operating the transmitter, records mechanically all signals transmitted on a paper tape, which is only accessible to a duly authorised inspector and cannot be tampered with by the operator. The ammeter, voltmeter and fuses are mounted on the same case within which the resonant circuits for tuning the apparatus to the incoming signals are placed.

The circuits are two in number. The aerial circuit consisting of variable inductance and variable capacity—placed in series or parallel at will—and adapted for reception on either of the commercial wave-lengths. Switches are provided for instantly changing from one commercial wave-length to another when listening for a call. The detector circuit is also variable by a similar method, and can be coupled to a variable degree with the aerial circuit and also with the detector proper. A potentiometer is provided for obtaining a suitable P.D. across the detector terminals. Two types of detector are used. These are mounted in similar ebonite cases provided with plug contacts, and are interchangeable. The entire station is controlled by one "master switch," which, by a single movement, makes all the changes in connection when it is desired to change from "send" to "receive," or *vice versa*.

The whole of the instruments are assembled in separate units which—when in position—form a cabinet; proper connections being made by suitable plugs. This construction enables the apparatus to be very rapidly installed, as the labour of wiring up the various parts is carried out at the factory.

For some considerable time the need has been felt for some method of recording automatically the messages received by "wireless." The receiving recorder originally used had so many disadvantages that it has been practically abandoned in all commercial stations. Its construction is necessarily complicated, consequently it is extremely difficult for the operator to maintain it in perfect adjustment, whilst the slightest variation results in inaccurate recording, which involves repetition and delay. Further, if a high degree of sensitiveness is required, the instrument cannot be rendered independent of atmospheric disturbances.

Under the international regulations, the majority of commercial messages are transmitted at approximately the same wave-length, and the receiving recorder is affected equally by all signals of all stations using a similar wave-length; whereas an operator using aural reception is not only able to effect an accuracy of "tuning," unattainable by the receiving recorder

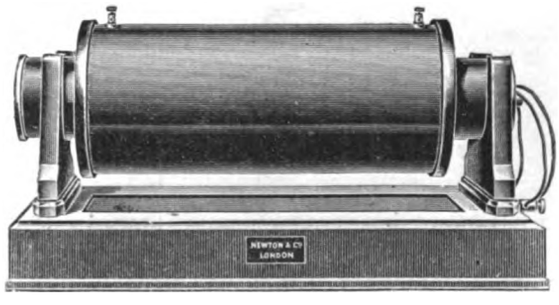
mechanism, but in addition is able to discriminate between signals transmitted from different stations using identical wave-lengths by distinguishing the characteristic sound or tone of his particular station, and is thus enabled to "read through" outside interference. Whilst the aural receiver is absolutely constant in its sensitiveness and requires practically no adjustment, the adjustment of the receiving recorder mechanism is constantly affected by vibration and change of temperature, which necessitates re-adjustment and much waste of time. It is also extremely difficult to maintain with the receiving recorder a speed of 20 words per minute, as required by the government regulations.

The Helsby Company's automatic outgoing signal recorder is used at the transmitting station. This instrument accurately records all signals transmitted by the operator, and furnishes an independent means of detecting any inaccuracies or breach of the rules laid down by the International Convention for the conduct of traffic. The instrument is mechanically operated and is entirely free from atmospheric disturbances. It is impossible for the operator to transmit any signals without actuating the recording device. If desired, the instrument can be locked and be made only available for inspection by a duly authorised official. The standard speed of 20 words per minute is easily recorded, while any variation in that speed is indicated.

This system therefore opens up an entirely new field, and one which is extremely valuable. Among many of the uses to which it can be applied are the following: (1) To establish intercommunication between the several galleries in coal mines, also from the galleries to the station at the mouth of the pit. (2) To establish communication with submarines, enabling the vessel to keep in touch with the parent ship. (3) To establish communication between island forts, also with forts on the coast. (4) No aerial masts being necessary, and the apparatus being extremely portable, it is specially adapted for military service.

Newton's Induction Coils for Wireless Work.

In the development of many of the present-day systems of wireless telegraphy the induction coil has played an important part, with the result that it has ceased to become merely a



"INSTANTA" COIL OF MESSRS. NEWTON & CO.

laboratory instrument and has entered the industrial world. Messrs. Newton & Co. have a wide experience in the design and manufacture of these coils, and some details of the class they have built up for wireless work for the Admiralty, and which we show in the accompanying illustration, will doubtless be of interest.

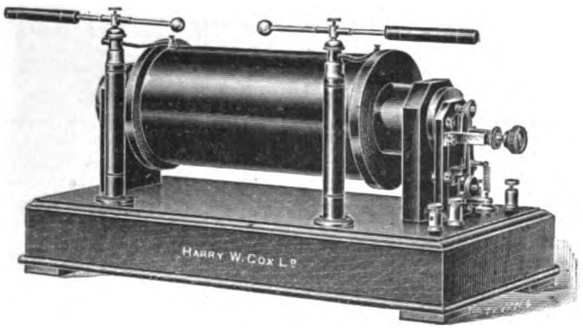
The coil is known as the "Instanta." These coils are chiefly intended for use with mercury breaks, but they can be, and often are, used also with the electrolytic interrupter; but where the latter is intended to be employed, Messrs. Newton have designed a coil of different proportions, though based on the same general principles. Briefly, the "Instanta" coil is an "Apps-Newton" coil with a stronger magnetic field and lower secondary resistance. The importance of a low secondary resistance can hardly be over-estimated. It is impossible to get a really heavy output from a coil if the internal resistance of the winding is too high. This is a point too often overlooked in choosing a coil. The present accepted standard of spark length as a means of measurement is, Messrs. Newton point out, totally misleading, especially as it is both easy and cheap to get a long spark by winding the secondary with very thin wire, but at the expense of great loss of efficiency and output. To take an example: The secondary resistance of a Newton 10 in. coil averages about 5,000 ohms, while two coils of similar size (one quite a new one) by other makers that have recently come into Messrs. Newton's hands measured 15,000 and 21,000 ohms respectively! This is as if one compared a dynamo giving, say, 1 ampere at 100 volts, with a dynamo giving 4 amperes at 100 volts. Both could be fairly sold as 100-volt dynamos, just as both these coils could be sold as 10 in. coils.

The "Instanta" coil can be supplied either on a polished mahogany cradle or on a bracket to fix against the wall. Like all Messrs. Newton's other best quality coils, it is covered throughout in polished ebonite tube, and is an extremely handsome and well-finished instrument. The primary winding has no less than 10 different adjustments, so that it can be exactly and easily "tuned" to the very best conditions for work with the electrolytic break, while a third connection is always in correct adjustment for a mercury interrupter.

The secondary is wound by special machinery, which has been designed and constructed entirely by Messrs. Newton for the purpose. It consists of a great number of thin sections, each containing some hundreds of turns of fine wire. The winding of these sections is so arranged as to distribute the electrical strain evenly throughout the coil, and is so carefully done that breakdowns are said to be practically unknown. After winding, the entire secondary is soaked in an insulating wax, and allowed to cool in a large vacuum tank, thus excluding all air bubbles, and still further ensuring the coil against breakdown.

Wireless Telegraph Coils.

The coils used for wireless telegraphy differ from the medical coils chiefly in their rather heavier winding, which allows a greater quantity of electricity to be charged into the condensers at each interruption. In conformity with prevailing ideas,



COX'S INDUCTION COIL FOR WIRELESS WORK.

Messrs. H. W. Cox & Co. always wind these coils on the multi-section principle, though, as a matter of fact, they consider the advantages of multi-section over two-section winding as somewhat over-rated. There is undoubtedly the advantage in multi-section as regards the smaller electrostatic capacity, but it should be noted that this does not necessarily involve any loss of energy, as it merely means that a slightly greater percentage of the displaced energy is retained in the coil windings and never finds its way to the condenser, but this energy does not escape, and beyond the C^2R loss there is no actual loss involved; on the other hand, the cylindrical winding allows a considerably smaller mean winding diameter to be used on the secondary, thus greatly reducing the resistance for any given spark-length, and the leakage of electricity to air is less in this type of coil than in the multi-section.

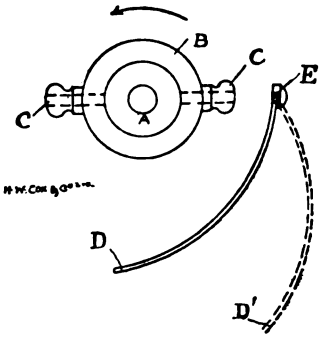
Digitized by Google

These coils are also made with "taper" insulation, *i.e.*, specially constructed for "earthing" one terminal. This is an important point, as the "earthing" of one terminal doubles the strain on the other, and in many makes of coil this fact is not allowed for, whereas if it is allowed for in the ordinary

COX'S MERCURY BREAK APPARATUS.

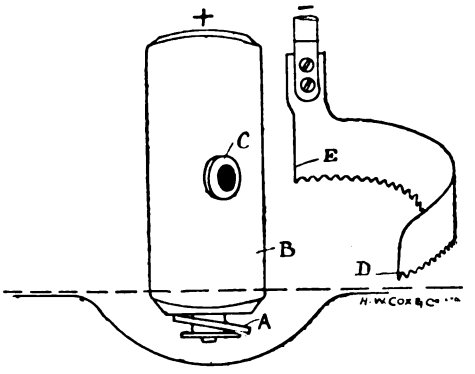
way there is a large amount of useless insulation on one end which brings down the space factor.

The illustration shows the latest form of the well-known Cox jet interrupter, and includes several important improvements, of which the chief are: (*a*) Any current up to 30 amperes may be used without injury to the break, while the regulation is so



PLAN OF COX'S JET BREAK APPARATUS.

complete that the current passing through the coil can be varied from practically zero to the maximum with no other control; therefore no current is wasted through the heating of a resistance. (*b*) By an ingenious mechanism a large resistance, approximately 200 ohms, is put into circuit at the



ELEVATION OF COX'S JET BREAK APPARATUS.

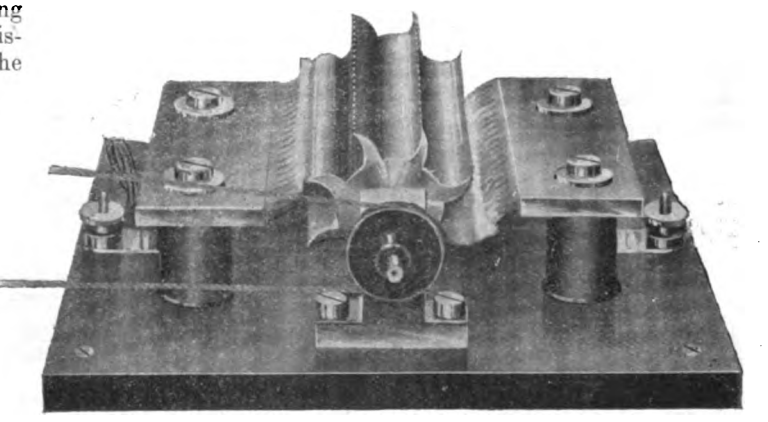
moment current is "made" and is gradually taken out, so that when the current is broken the resistance in circuit is practically nil; consequently a minimum amount of inverse current is induced in the induction coil. This latter is a most important factor in X-ray work. The inverse current hitherto always produced by mercury jet breaks, blackens and destroys the focus tube and also causes the blurring of the image on the plate. Many attempts have been made in the past to suppress this inverse current by switching in a large resistance at the moment of make, but hitherto these attempts have not been successful in practice. In the present case the desired effect is obtained in a simple way, which is explained in the accompanying diagrams.

A quick screw thread, the end of which is shown at A, is cut internally upon the barrel B, which, being driven by an electric motor, pumps up mercury from the reservoir and discharges it from two nozzles C. The mercury stream during parts of its revolution strikes against the fixed blade, making contact at the point D and breaking at E. By swinging the blade the arc of contact is increased or decreased and the time allowed for the current to grow in the primary circuit of the coil is varied at will. The nozzle is shaped in such a manner that, shortly after leaving it, the mercury begins to split up and to form nodes or constricted portions having considerable resistance; consequently at D or D′ the resistance in circuit is very considerable, and this resistance is gradually removed until at the break at E the only resistance is that of a $\frac{1}{4}$ in. of solid mercury jet, which is practically nil.

Wireless Apparatus.

Although only recently introduced, the Balsillie system of the British Radio-Telegraph & Telephone Co. has made considerable progress. The wireless apparatus used by the Company was first shown at the Physical Society's Exhibition last December, and a description of the system was given in THE ELECTRICIAN (January 7, 1910). It is a weakly-damped wave system embodying improvements in sharpness of tuning, freedom from damping and simplicity of apparatus, and its main feature, perhaps, is the rotary spark-gap employed. Attention may be called to the fact that, the tuner and detector being contained in one piece of apparatus, the receiving station is very portable. In fact, the compactness of the apparatus may well be claimed as another feature of the system. We understand that the Company have recently been honoured with a large Admiralty order for wireless apparatus. The rotary spark gap is illustrated herewith.

It may also prove of interest to mention that the Company are now obtaining very promising results with their system for wireless telephony; and we understand that they have been successful over a distance of 30 miles. The wire-



ROTARY SPARK GAP OF THE BRITISH RADIO-TELEGRAPH AND TELEPHONE CO.

less telephone has hitherto been too complicated for ordinary marine work, but the Company are of opinion that adaptation of a spark system to this form of wireless transmission will open up a most promising future

The Use of Electrical Power for Auxiliary Purposes on Board Ship.

BY JAMES A. SEAGER.

Summary.—The author deals with the use of electricity on board ship for general purposes, and the causes that militate against its adoption. The chief of these are the want, in most cases, of definite specifications for the plant required, the ignorance of electrical matters on the part of engineers on board ship, the lack of skilled attention, the desirability of simplicity in equipment, and the cutting of prices. The voltage used is preferably low for safety, but the use of electric power tends to raise the standard adopted. Although there is a tendency to run all auxiliaries electrically, it is safer to have some of them independent of the electrical plant. To a large extent the adoption of electrical auxiliaries resolves itself into a question of first cost *v.* running cost. The article concludes with a reference to examples of auxiliaries now in use, and emphasis is laid upon the necessity for good workmanship and ample size of plant for the requirements.

The application of electricity to the mercantile marine is a subject which at the present time appears to be exciting a very considerable amount of attention in this country, and in view of the various schemes which have been put forward for this purpose the problems raised have assumed a very complicated aspect. It may, therefore, be of interest to touch briefly upon the various phases of this question, more especially in relation to the use of electricity for auxiliary power purposes.

Such reference, however, cannot be made without previously considering one or two points regarding the generating plant and general lay-out of ships' lighting and power equipment, and also a consideration of some of the human elements which very powerfully affect the more purely engineering aspects of the question. In this article it is proposed to disregard Admiralty practice, except where such practice is coincident with, or has a bearing upon mercantile work, inasmuch as a satisfactory solution of engineering problems has a relation to commercial cost, and in Admiralty work this consideration is subordinated to a very much greater extent than in mercantile work, and conclusions drawn from Admiralty practice might be erroneous if applied to the mercantile marine.

Dealing first of all with the personnel on board a trading vessel or concerned with its equipment, we have to remember that in the majority of cases there is no analogy to the consulting engineer who is so often conspicuous in land practice. The result is that very often the requirements for a ship's electrical equipment, more especially as regards the auxiliaries, are conveyed to the manufacturers in such vague terms that they are left to imagine what these requirements are, and there is therefore a large opening for disparity in the tenders. It is not an uncommon thing, for example, to find an inquiry for an electric winch in which the only information given is that it has to be of equivalent strength to a steam winch whose capacity is given in terms of the size of the cylinders, no data being available as to the speed of rope required or the maximum load to be handled. The result of this is that the maker confronted with such an inquiry sends in a tender for the plant which he thinks will sell best and trusts to luck for the results. Not only is this the case but it can often happen that prior knowledge of the particular line of steamships is a positive disadvantage to a maker who is asked to tender to a loose specification inasmuch as the firm with such knowledge will be expected to quote machinery which will be suitable in the light of their experience, while an outside firm will very probably put in a price for an unsuitable plant which may be sufficiently tempting to make the offer acceptable to the owners of the vessel. In such a case, if trouble occurs, the owners will have no remedy unless they have given explicit instructions to the new firm they have admitted. This explains what may at first appear rather curious, that firms with the most experience of marine auxiliary work frequently put in the highest tenders, the reason being that they know much more fully the special difficulties to be encountered and take adequate steps to insure safety. In this way the highest tender is often the cheapest.

The next point to remember is that either the owner of the vessel, who is a non-technical man, does the buying, or at best advice is taken from a marine superintendent. The distinguishing feature of the latter is often a profound conservatism which excludes not only everything electrical so far as possible, but even such apparatus as water-tube boilers which are now so common in land practice that it is almost a miracle that they are so rarely found on board a merchant vessel. One of the reasons for this is that so far as electrical engineering is concerned the marine superintendent attained his practical sea-going experience on which the present recommendations are founded before electricity was anything more on board even the best boats than a small adjunct for lighting purposes, and hence the electrical manufacturer of to-day has in some cases to fight prejudices created by the behaviour of plant some 15 or 20 years ago. Moreover, the majority of chief engineers on board vessels, who have a very powerful voice in the choice of plant, prefer often not to introduce new engineering features for reasons to be mentioned.

Another thing to remember is that on board ship there is not the same amount of skilled attention as is obtainable ashore. In the stokehold the labour is of the lowest type, and it is difficult to train such men properly to the use of electrical machinery. On deck, such apparatus as winches and capstans are operated by stevedores who are perhaps the most careless set of men it would be possible to find for the manipulation of machinery. The average marine engineer knows very little of electrical power work, and therefore any complication of electrical machinery, however desirable it may be from a technical point of view, is apt to be viewed with suspicion on board ship. As an instance it is well to remember that even ship lighting sets are practically universally run, not in parallel, but on separate bus bars with change-over switches or plugs for the various circuits.

Turning from the personnel of the ship, there are one or two other points which have a very important bearing. The first is that on board ship minor accidents are always occurring, and the facilities for repair while at sea are very limited. This tends to the utmost simplicity of parts and the elimination of highly technical apparatus. The continual racking and straining of a vessel tends to displace the mechanical and electrical parts of its equipment in a way that is unknown on shore, and hence everything must be as simple and as strong as possible. In many instances plant has to be crowded into a space which is almost inadequate for it and cannot be subject to regular inspection, more especially in the case of auxiliary and spare plant, which suffers extremely in this way. Such plant has therefore to be made so as to be almost automatic in maintenance and capable of long and hard usage without adequate supervision.

In many instances plant is shut up in close spaces at high temperature and the heating limits of the motors have, therefore, to be very low. Unfortunately, this is not always attended to, inasmuch as British ship owners are beginning to feel the keen edge of competition in a way to which they have been unused and they are therefore cutting prices on electrical

equipment for auxiliaries in a manner which is very baffling to good design. Besides all this is the constant trouble of water combined with salt which unless carefully guarded against causes leakage and corrosion. Auxiliary apparatus must, in addition, be so strongly insulated and protected as to withstand moist and yet hot atmospheres, particularly in vessels designed for the Indian and African trading routes.

A recapitulation of the above points will seem to be necessary when one comes to consider the first problem with regard to the design of the auxiliary power equipments of a vessel, namely, that of the most suitable voltage. Prof. Gisbert Kapp, in his address at the dinner of the Newcastle local section of the Institution of Electrical Engineers last winter, referred to the important point of the standardisation of voltages on board a vessel, and laid special emphasis on the necessity of this work in order to standardise manufacturers' products and cheapen the cost of ship installation work. He then stated that so far as the Newcastle area was concerned there appeared to be an informal standard of voltage of either 65 or 110. Though this at present is correct it appears that various causes are combining to render it a transition stage. We are finding in modern ship equipments the effect of a compromise between the most suitable lighting voltage which in view of the constant vibration and the use of portable lights should be as low as possible, and the power requirements, the voltage for which in view of the heavy transmission loss of large power should up to a certain point be high. It will be remembered that the Admiralty, which has adopted electric power to a very considerable extent for auxiliary purposes, have recently used 220 volts, while in at least one instance a voltage of 500 has been adopted on board a foreign vessel. This is, however, in view of the confined space and the possibility of leakage, a high voltage to use. It would appear that 220 volts is about the superior limit which should be adopted for power purposes, and if the problem were limited to a question of what proportion of lighting and proportion of auxiliary power is to be placed on the ships' generating set, the theoretical solution would be a mathematical compromise between the two convenient voltages for the purpose. At the present time, however, the problem is not so simple as this, inasmuch as quite apart from the long series of odd voltages which a mathematical compromise in every case would induce, there appears to be a strong probability that in the comparatively near future high-speed turbine power, combined with electrical main propulsion, or the use of suction producers and gas engines, may find their place. In the latter case, all auxiliaries will perforce be driven electrically, and the question of lighting supply will be subordinated to the problem of the most convenient means of auxiliary power supply. At the present time it may be suggested that, at any rate for the larger vessels, two separate systems may be introduced, one at a low voltage for lighting, the other at a higher voltage for power, and run by separate generating sets.

This discussion leads us to a consideration of the extent to which electric power can be safely used for the purpose of driving auxiliaries. On large liners the tendency is becoming more and more in the direction of operating the condensing plant, forced or induced draught fans, pumps, &c., as well as the deck plant, by means of electric power, and reference need only be made to the very complete fan equipment of the "Lusitania" and "Mauretania," by Messrs. W. H. Allen, Son & Co., of Bedford, who supplied 32 69 in. single inlet fans to each of these vessels, all electrically driven, in order to emphasise this point. There is, however, a feeling that this wholesale substitution for steam plant must not be pushed too far, as in the event of a breakdown of the generating sets or the switchboard the whole of the auxiliaries would be at once thrown out of action. That this feeling is only reasonable is shown by the fact that many land engineers responsible for the construction of electrical generating stations take the same view and a middle course is adopted, as for example at Birmingham, where half the condensing plants are operated by means of steam and half by electricity.

Another factor which determines the extent to which auxiliary plant may be run electrically is the question of the proportion which an owner of a vessel is prepared to place between first cost and economy in running. Unfortunately, at the present time ships are being built and equipped at such a cut price that it is impossible to carry out everything electrically, even if this were approved on technical grounds. The question of working the winches by steam or electricity, for example, very largely depends on the kind of trade for which the boat is intended. If the vessel is meant for making short trips and frequent calls the economy in working the cargoes by having electrical installations is very marked, inasmuch as the hours per year during which the winches are run are very considerable. On the other hand, if a vessel is making long voyages, the question of economy in running plant which is idle except at the beginning and end of a voyage becomes of minor importance, and the increased first cost of electrical, when compared with steam, winches is then the most prominent factor.

Speaking broadly, the question of extent to which auxiliary electrical power may be applied, resolves itself into an estimation of the amount which the owner of the vessel is prepared to pay, and this will probably first be spent on electrical plant which is in continuous or frequently intermittent use such as condensing plant, pumps, draught fans, &c., and then, if there is still money to spare, the question of the more intermittent load will be considered and the question of equipping the deck machinery electrically will follow. At the same time, it is well to bear in mind that marine engineers are fully alive to

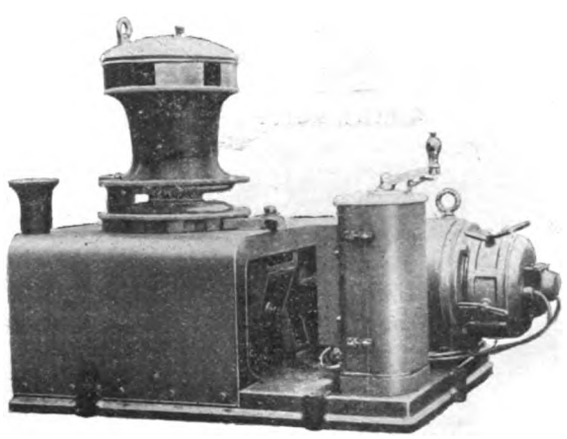

FIG. 1.—ANCHOR CAPSTAN. 1 TON AT 45 FT. PER MINUTE.

the inconvenience of having long lengths of steam piping on deck subject to stand-by losses, possibility of fracture due to frost or bad warming up or draining, and careless handling by the deck hands. Marine engineers are at present very well aware that, especially on passenger vessels, the steam pipe distribution to auxiliaries is an inconvenience which should be avoided as far as possible, both from the point of view of possible explosion in which passengers may be involved, and also in many cases because such steam pipes heat up confined spaces to an uncomfortable degree. Other considerations in favour of the electrical drive of auxiliaries on board passenger vessels are the high degree of silence and cleanliness in the electric motor compared with its steam rival.

Another point which has a bearing on this question is the load-factor which is to be placed upon the generating plant. It is evident that so far as possible the electric load on the generator should be kept as uniform as possible, in order that a small generating set should be used which will nevertheless fulfil the maximum requirements placed upon it at all times. With the increase of the number of purposes for which electric power is required on board ship, there is an increased chance that the load factor on the generator will become greater, and in this connection the steady run of induced draught fans exercises a beneficial effect, quite apart from the possibility of the delicate control of the steaming performance of the vessel by electrical regulation of forced or induced draught. other end of the scale, an electrical steering gear is, and has been, quite a feasible thing inasmuch as a motor can easily be arranged to drive through a worm-wheel gear the usual right and left-handed screw steering gear, or to operate a hand-steering gear by means of placing a motor in the position usually occupied by the steam steering gear which is at present attached, but when the helm is placed hard over a heavy "peak" load is thrown on the generator.

Turning now to the question of the transmission of power from a generator to the auxiliary electrical plant, this has already been incidentally touched upon above. The obvious solution to the voltage difficulty would be the adoption of a simple three-wire system, and it would at first sight appear that this would find favour among marine men, inasmuch as the single-wire system with earth returns which was once so popular is now almost entirely out of favour, partly on account of the necessity of a mixed system near the ship's compasses, and also because an earth return has led to serious earths and short-circuits. In a single-wire system any fault would immediately produce a short-circuit, while with the two-wire a fault to earth on one pole could be located and removed before anything occurs on the other pole to cause a short-circuit. It is, however, doubtful whether in a power installation where parallel running appears to be too complicated a three-wire

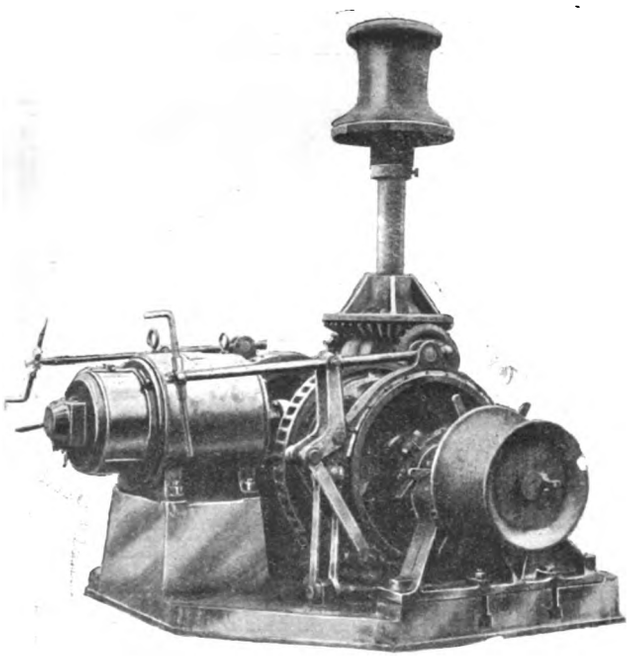

FIG. 2.—WINDLASS AND CAPSTAN FOR $1\frac{5}{16}$ IN. ROPE.

system could be introduced, inasmuch as the engineers on board ship are continually changing, and no sooner would a man be brought up to the standard of three-wire running than he would get another berth. Probably the best arrangement if this were tried on a ship's equipment of considerable size would be to arrange for each set to consist of two generators driven by one engine, these two generators being connected in series with one another, the middle wire being connected to the junction, the lighting being carried equally on the two generators, while the power supply was obtained from the outer wires. As the out-of-balance lighting load with proper distribution arrangements would never be considerable this arrangement should operate with simplicity and satisfaction.

The chief points to insist upon at present with regard to the power and lighting connections are that every circuit shall be brought back to an efficient dividing box, that mechanical joints only should be allowed, and that the system of fusing shall be comprehensive, complete, and so locked as to be only accessible to the electrician in charge. The control mechanism must be of an extremely solid and substantial description, and all rheostats should be constructed of material which will not deteriorate in a moist and salt atmosphere.

The question of controllers is one most vital to the reputation of electrical auxiliary machinery. Owing to the price cutting to which reference has been made above, a good many controllers supplied to the mercantile marine are foolishly inadequate for the work they have to do. The current-carrying capacity is far too small, and in some cases their manufacture is of a most flimsy description, when the conditions under which they will be used by, say, deck hands, is considered. An examination of some of the winches at present on the market will show that, owing to the desire to skimp prices there is absolutely no room left for the provision of a controller of a decent size, and this condition of things is likely to continue until either ship owners see the necessity for having

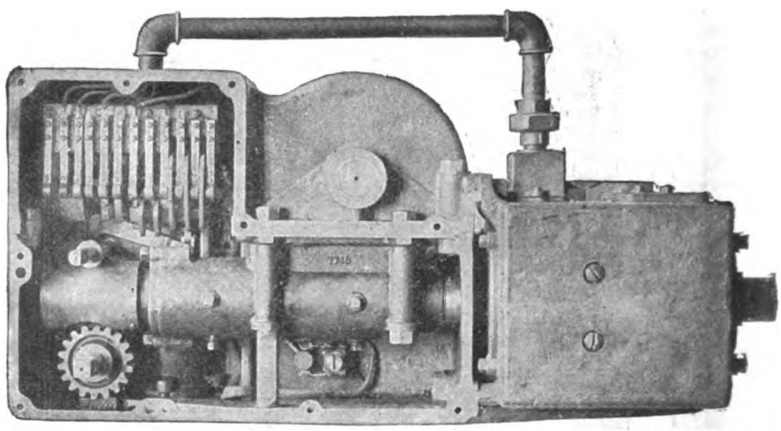

FIG. 3.—MOTOR AND SAFETY CONTROLLER FOR WATERTIGHT DOORS.

consulting engineers capable of specifying adequate provisions for safety, or until electrical manufacturers combine to produce a standard specification from which they will not depart.

The subject of electric winches and capstans, although an integral part of this discussion cannot be fully dealt with in an article of the present length. By the courtesy of Messrs. Clarke, Chapman & Co. (Ltd.), Figs. 1 and 2 illustrate typical forms of capstans which are designed to meet the conditions of marine practice found as the result of considerable experience and yet complying as far as possible with the marine demand for low cost. Fig. 1 shows an anchor capstan capable of operating a weight of 1 ton at 45 ft. per minute, while Fig. 2 shows a combined windlass and capstan for $1\frac{5}{16}$ in. rope. The

FIG. 4.—EMERGENCY STATION ON THE BRIDGE.

use of electric winches and hoists on board ship is now becoming increasingly popular for purposes ranging from small whips for light baggage and provisions to elaborate passenger hoists, equal to those found in hotels, and which are now installed in many of our liners. The same trouble of price cutting is, however, becoming increasingly apparent, and unfortunately a winch for cargo working lends itself admirably to high rating. A winch may be specified to deal with 30 cwt. at 100 ft. per minute, and an unscrupulous manufacturer may put in a motor which would only do this work at a cost of

immense over-heating. As, however, the majority of the packages carried by a vessel on several consecutive voyages may be only 15 cwt., the trouble may not be found until by some chance the ship is loaded with cargo up to or even above the normal rating of the winches. The electrical gear then, of course, fails, and odium is cast not only on the maker who has supplied inadequate plant, but on the whole electrical industry. As, however, the plant by this time will be paid for and the guarantee time expired, the owner of the vessel has no remedy. Other points in connection with winch design are that winches, capstans and whips should be waterproof, which is best effected by making each separate part such as the motor and controller entirely waterproof; but the minimum degree of safety with regard to deck machinery should be that weather and water washing about the decks should not be able to get at the electrical conductors. For electrical plant which, is to be installed in such situations as the well of a cargo steamer, it is necessary to guard against the possibility of total immersion of the gear. Such apparatus should also be as "fool proof" as possible, that is to say, that in view of unskilled handling by stevedores and similar types of labour, the controllers of such gear as winches and capstans should not only have arrangements whereby the stops of the controller are indicated, such as the star wheel device on the ordinary tramway type of controller, but if possible, arrange-

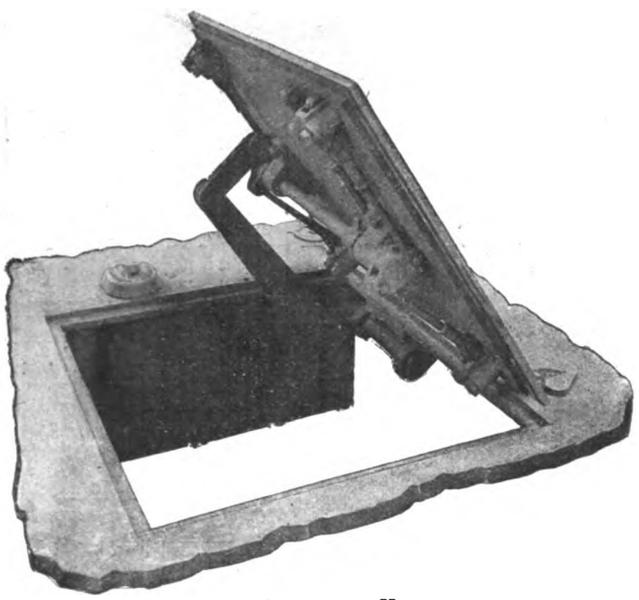

FIG. 5.—WATERTIGHT HATCH.

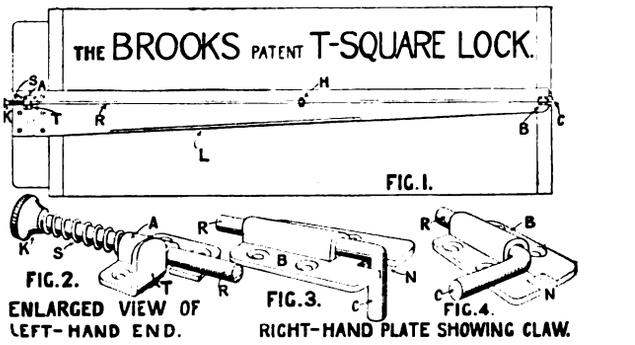
ments should be fitted so that it is impossible to hold the controller in intermediate positions in order to avoid the burning on contacts due to careless usage. An appliance of this description has recently been placed on the market. A recommendation which may be of value is that magnetic brakes, although more costly than the ordinary foot brake, are of considerable value in increasing the life of winches and capstans, inasmuch as by this means the control of an electric winch approximates more nearly to that of the steam winch.

There are a considerable number of minor applications of electric power for auxiliary purposes on board ship to which reference could be made if space permitted; but perhaps one example will be sufficient to show the possibilities in this direction when marine engineers have been educated up to them. This is the electrical operation of watertight doors which has been developed by the British Thomson-Houston Co. (Ltd.), a feature which, if adopted, will go far to increase the practical availability of the watertight bulkheads of a vessel in case of collision or grounding. The electrical system to which reference is made has a central emergency station on the bridge for closing all the watertight doors, together with a lever action on each door, whereby a man at any door can open it at any time during an emergency period, the door then automatically closing again. Means are also provided whereby the current is automatically shut off when an obstruction fouls the doors, the circuit being then automatically closed again, and so closing the doors the moment the obstruction is removed. This renders the burning out of fuses avoidable. The watertight doors are provided with a specially designed electrical motor and safety controller, shown in Fig. 3, while the emergency station on the bridge is shown in Fig. 4. Indicator lamps fixed on this show at any time the position (open or closed) of any door, and in the case of local obstruction will point out the door to be cleared. The switching mechanism does not start all doors operated by the emergency station at the same time as this would impose a very heavy load on the generator in the event of a large number of doors being installed. There is a time difference of about three seconds between the operation of each motor. The operation of a single door requires about $\frac{3}{4}$ H.P. for 15 seconds, while by the delay action a group of 24 doors can be closed in under 70 seconds with about 5 H.P. on the generator. Similar mechanism can be adopted for watertight hatches (Fig. 5).

Another application of electric power to auxiliary purposes which has not up to the present received the amount of attention which it deserves is the operation of refrigerating plant. Nearly all modern passenger vessels of medium and large capacity, together with the important class of freight vessels engaged in the produce carrying trade are fitted with systems of refrigeration worked on the carbonic acid or ammonia process. This involves the more or less continuous use of power for the pumps, and it is here suggested that this use of power which is of a continuous nature should be one of the useful applications of electricity on board ship.

Enough has been written to show that the installation and operation of auxiliary plant on board ship is by no means the easy proposition which some electrical engineers appear to imagine. At the same time there are possibilities of immense advances to be made in this direction and it would therefore be to the advantage of electrical manufacturers and engineers to interest themselves more largely in determining the conditions in which power may be applied as auxiliary service in the mercantile marine.



The BROOKS Patent T-square Lock is a simple device, which can be attached in a few minutes by means of a few small screws (supplied) to any ordinary T-square, enabling the latter to be locked in any position on an inclined or vertical drawing board, thus setting both hands free to manipulate the set square, &c. The T-square may, nevertheless, be shifted with the same freedom as an ordinary T-square. Provided with this attachment the draughtsman has all the convenience of an expensive drafting machine, together with the accuracy of the T-square.

No alteration or addition to the drawing board is necessary.

The metal parts are all nickel-plated and polished.

The rod R slides in plates A B; spring S presses knob K to the left, thus pulling claw C against one edge of board and the stock of the T-square against the other. To release, the finger presses K to the right, the thumb resting against T, thus pushing C out of contact with the edge of the board. The ledge L is provided for attachment to the blade of the T-square for holding compasses, &c.

Apparatus complete (with nickel-plated screws), ready for attachment, 4/6 (for applying to boards not exceeding 24 in.); and 5/6 (for applying to boards not exceeding 54 in.).

When ordering, give width of your board, breadth of T-square stock, and length of blade from inside edge of stock.

Write also for leaflets of the Brooks Flexible Curves, Corner Curves (for drawing in fillets, &c.), Mathematical Curves and Pinro (pinning strip).

"Witton" Power Plant for Ship Work.

The modern battleship and passenger carrying vessel are built by the aid of electrical machinery and equipped with electrical plant of one class or another. The electric driving of large tools in shipyards is now regarded as a sign of progress, and any shipbuilding establishment is considered incomplete if it is lacking in this respect. Similarly on board ship it is not sufficient that the vessel be electrically lighted. The auxiliary plant and machinery must be electrically driven.

The General Electric Co. has completed numerous installations of "Witton" dynamos and motors in shipyards and on many important passenger boats. At its large engineering shops at Witton, near Birmingham, the Company is able to produce the whole of the heavier pieces of electrical machinery for ship and dock and harbour power plants. Generators, switchgear, motors, and starting apparatus all emanate from Witton, and bear that distinctive name. It would quite naturally be difficult to describe the many examples of "Witton" dynamo and motor installations in connection with marine work, but the adjoining illustrations are of interest in that they depict some of the latest work done with "Witton" plant.

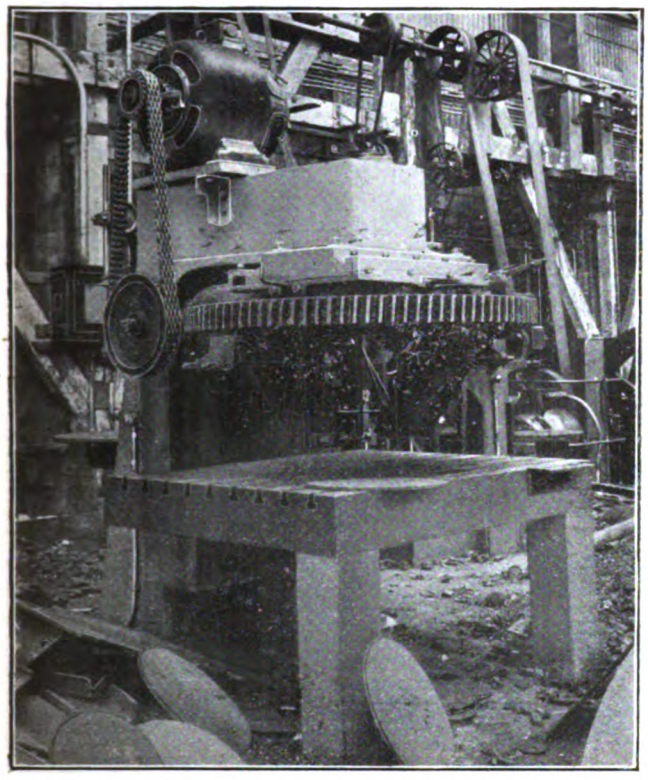

FIG. 1.—PORTHOLE CUTTING MACHINE DRIVEN BY "WITTON" MOTOR.

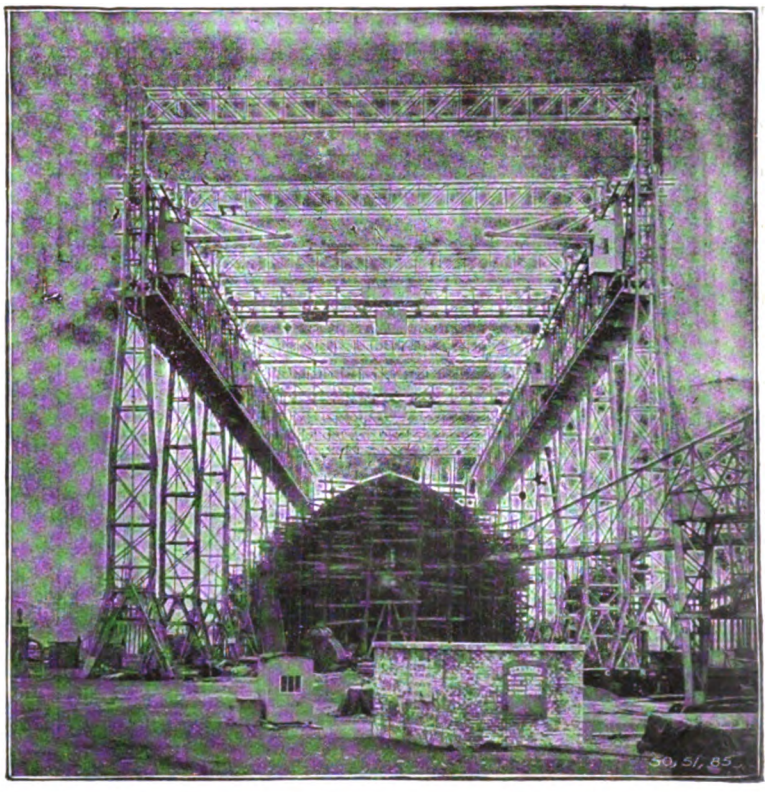

FIG. 2.—TWO OVERHEAD TRAVELLING CRANES DRIVEN BY "WITTON" MOTORS IN SHIP'S BERTH.

In shipyards and marine engineering shops it is customary to drive all the heavy tools with an independent motor. Fig. 1 shows an interesting tool operated by a "Witton" motor, which is mounted directly on the frame of the tool. The motor develops 10 H.P., and is chain-geared to one of the lay shafts, from which the power is suitably transmitted to the rotary

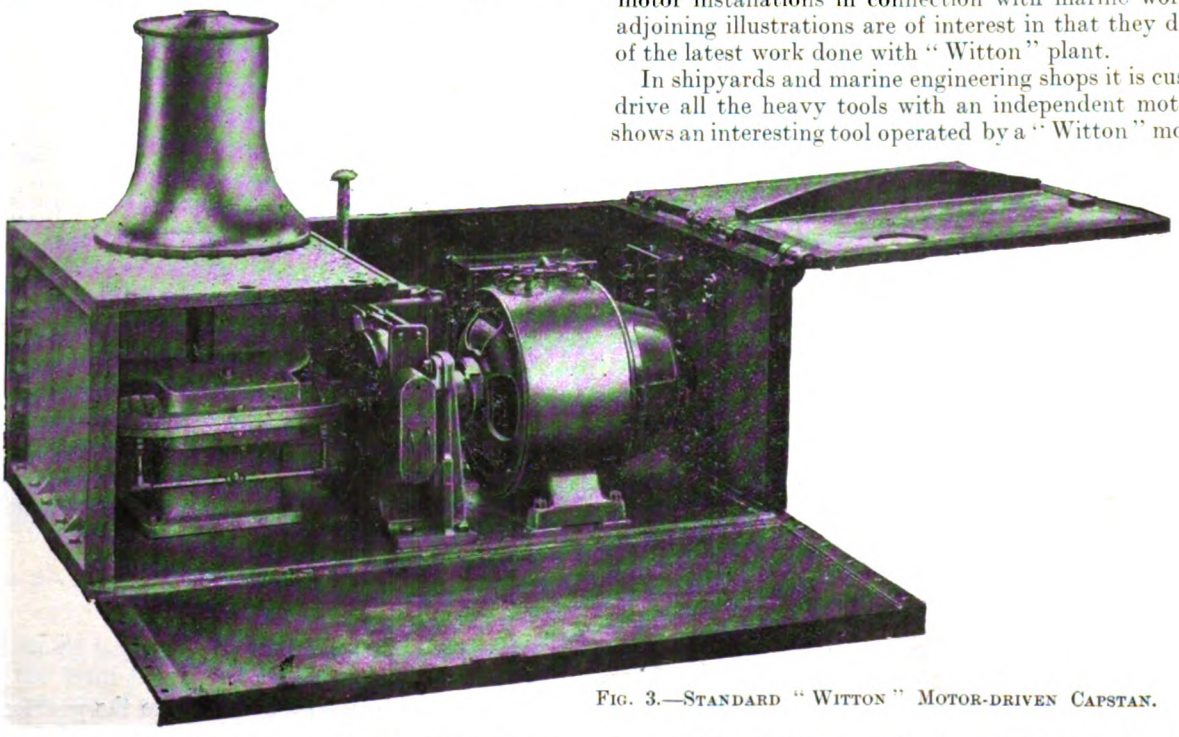

FIG. 3.—STANDARD "WITTON" MOTOR-DRIVEN CAPSTAN.

Digitized by Google

cutting tools. This machine is interesting in that it is employed for cutting portholes out of ship plates. The holes are clean cut and completed in this tool, as the discs lying at the side of the machine clearly show.

"Witton" motors are also installed to a considerable extent for crane operation, and Fig. 2 shows a ship's berth which is fitted with two overhead travelling cranes driven by "Witton" motors.

Fig. 3 shows a standard pattern capstan fitted with "Witton" motor. This has been installed in large numbers on docksides railway sidings, goods yards, &c. It is noteworthy among devices of this kind for the accessibility of the motor and driving gear. The top cover is hinged in two sections, and may be swung clear of the motor and starting gear. The latter is totally enclosed, and is operated by a pedal at the side of the capstan bollard.

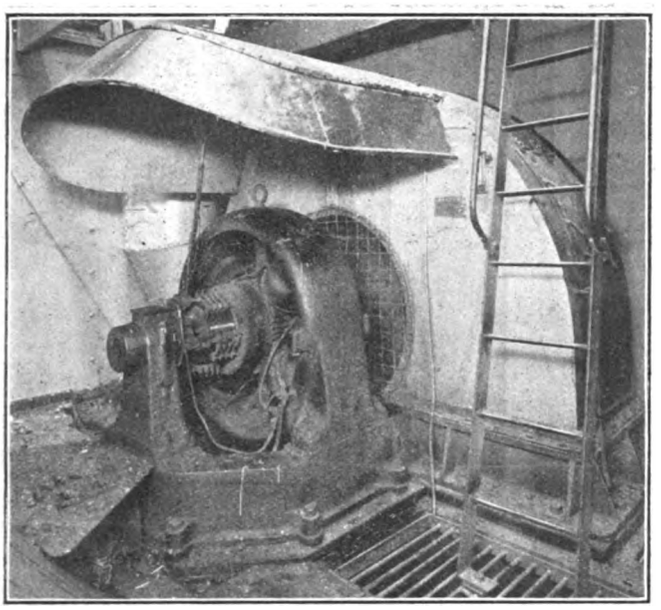

FIG. 4.—FORCED DRAUGHT FAN DRIVEN BY "WITTON" MOTOR ON R.M.S. "MALWA."

Fig. 4 shows one of the forced draught fans installed on this vessel and driven by a 25 H.P. variable speed "Witton" motor. The fan is direct-coupled to the motor, and a large hood is placed above the motor to protect it from falling water. All the auxiliaries on board this vessel are driven by "Witton" motors, which are directly coupled wherever possible to the machines driven.

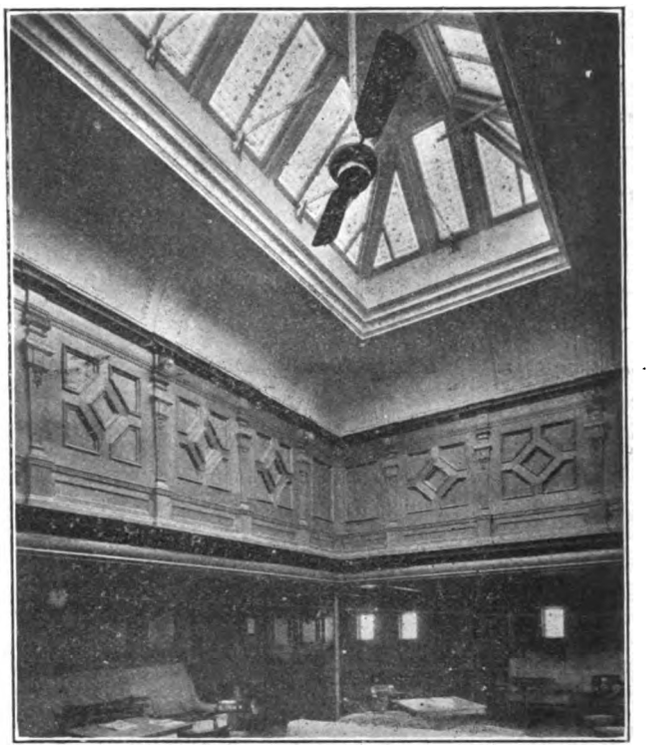

FIG. 6.—70 IN. "FREEZOR" FAN IN SMOKING ROOM OF R.M.S. "MALWA."

The cooling arrangements on the R.M.S. "Malwa" are very complete, and G.E.C. "Freezor" fans are installed. Fig. 5 depicts the interior of the saloon in which 12 70 in. and 16 20 in. fans are fitted. These fans are fixed to the ceiling, and are of the long or short stem type, according to the position of the fan. Fig. 6 shows the first-class smoking room of the same vessel, and a 70 in. "Freezor" fan depending from the skylight. In the same room four 16 in. bracket fans are in use.

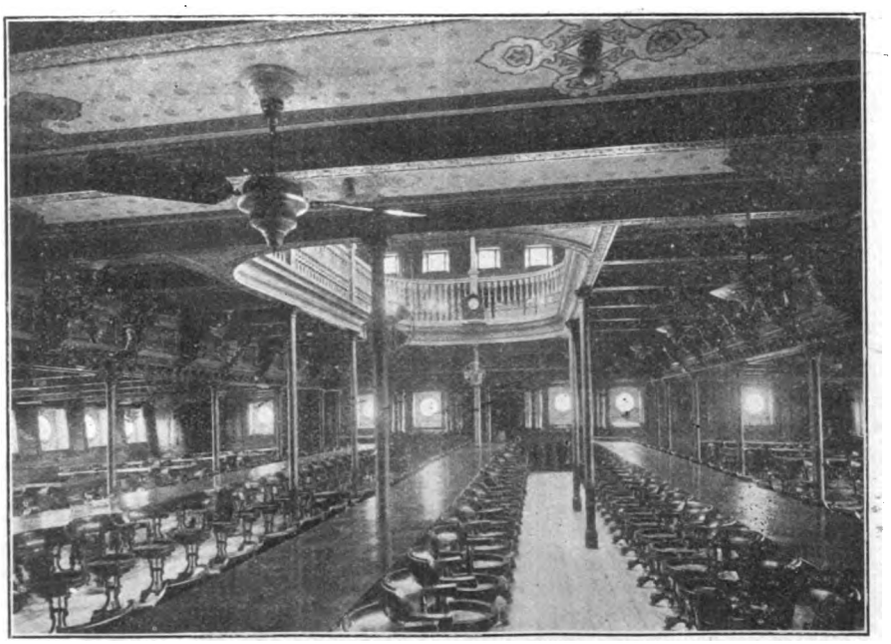

FIG. 5.—SALOON OF R.M.S. "MALWA," FITTED WITH "FREEZOR" FANS.

Of numerous ship installations employing "Witton" plant, that carried out recently on the R.M.S. "Malwa" is of interest. The whole of the electric power equipment comprises "Witton" dynamos and motors, switchgear and starting apparatus.

Bilge Pumping.

Not the least important of the operations on board ship is to keep the holds and lower parts generally free from bilge water, both for marine and hygienic reasons. To do this some sort of pump is required, and, all things being considered, an electrically-driven pump has some distinct advantages for this purpose. It is, therefore, not surprising to find many firms exercising their ingenuities in this direction.

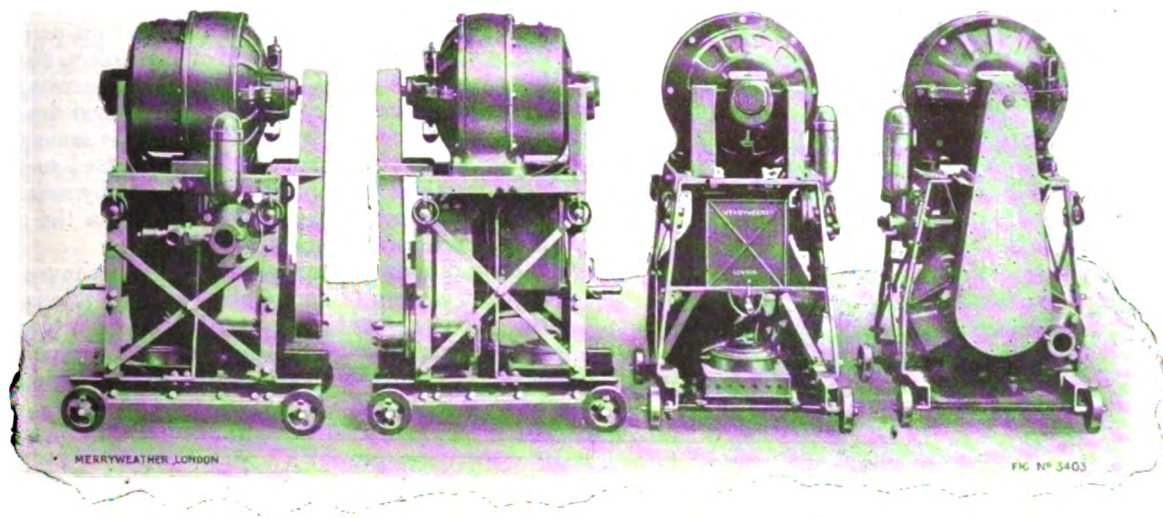

FIG. 1.— ELECTRICALLY-DRIVEN BILGE PUMPS.

Our illustration (Fig. 1) shows an electrically-driven bilge pump recently introduced by Messrs. Merryweather & Sons, of Greenwich. The "Hatfield" treble barrel pump has been employed under all sorts of conditions where water supply, general pumping or fire extinction is concerned, and the arrangement here shown has been designed for service on board ships as an auxiliary to the stationary steam bilge

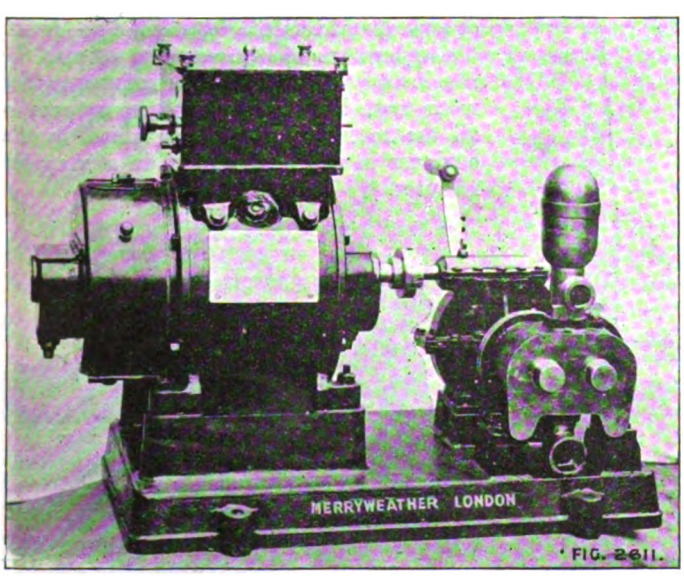

FIG. 2.—ELECTRICALLY-DRIVEN ROTARY OIL PUMP.

pumps, and should be found specially useful in harbour, when the fires in the main boilers are drawn so that the ordinary bilge pumps are out of service. For dockyards, and shipbuilding yards also, such a pump would prove a most valuable acquisition for keeping clear of water after launching, pumping out compartments after testing, &c., whilst a further point that merits consideration is the knowledge that it is always available as a fire pump, being capable of throwing powerful jets with the aid of flexible hose pipe.

The pump itself is constructed entirely of gunmetal, with three barrels arranged symmetrically round a steel crankshaft, and a polished copper air vessel is provided both on the suction and delivery. The electric motor is of the latest and most approved construction, and drives the pump by means of a special silent chain provided with suitable wrought-iron guard. The motor is fitted with controlling gear, arranged so that the pump can be worked at half or full power. The motor and pump are mounted upon a light and strong steel framework securely braced and stayed. Four rings are fitted to the frame for slinging purposes, and four small gunmetal wheels are provided for travelling.

The special features of the plant are lightness (the weight being about 9 cwt.), compactness in design and small floor space occupied. It can be lowered through a hatchway 3 ft. by 2 ft. 6 in., and its portability enables it to be easily conveyed to any compartment of a vessel where its services may be required. The pump has a capacity of 10 tons of water per hour, and will raise water by suction from a depth of 20 ft. or more without the aid of priming devices. It will deal effectively with water laden with oil or grease, a condition of things which is more likely than not to prevail in the case of bilge water.

Another interesting pumping equipment made by this firm is the electric and hand driven rotary oil pump shown in Fig. 2. It was supplied for use on H.M.S. "Russell." Its duty is to fill the supply tanks for an oil-engine generating set. The pump is capable of lifting oil fuel from a depth of about 10 ft. to a height of about 40 ft. above the pump.

A feature of this apparatus is that it can be worked by hand when inconvenient to run the electric motor, the pump being readily interchangeable from hand to motor gear, or vice versa. Another important advantage is that it is "silent" in working; and as the pump is equally adapted for pumping water, this point should commend it to those requiring a pump for service inside a building where the noise occasioned by the "thump of the pump" is objectionable. The pump is driven by means of a worm gearing with gunmetal wheel, steel worm with ball bearing thrust blocks, and running in an oil bath. The motor is an improved totally enclosed type, specially constructed to pass Admiralty requirements. It is watertight, and complete with double-pole switch and starting switch. The whole apparatus is mounted on a cast-iron bedplate, and forms a very neat and compact machine, the space occupied being only 3 ft. long by 1 ft. 8 in. wide, the extreme height being 2 ft. 3 in.

"Cyclone" Fans.

The ventilation of ships up to within a recent date was not looked upon very seriously, and the cowl fixed on the top deck, through which the foul air from below meandered in a lackadaisical fashion, was thought to be ample for all requirements. This fallacy, however, has now been exploded, and, thanks to the rapid strides which have been made in electricity, it is now possible to obtain that perfect ventilation on board ship which is so very necessary where hundreds of people are crowded together 'tween decks. The electrically-driven fan has remedied these one-time drawbacks, and among the most suitable for this purpose may be placed the "Cyclone," manufactured throughout by Messrs. Matthews & Yates, of Swinton, Manchester.

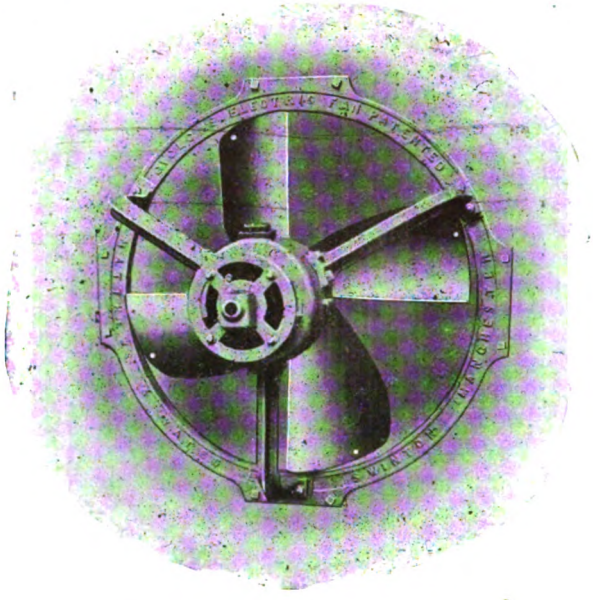

FIG. 1.—THE "CYCLONE" PORTHOLE FAN.

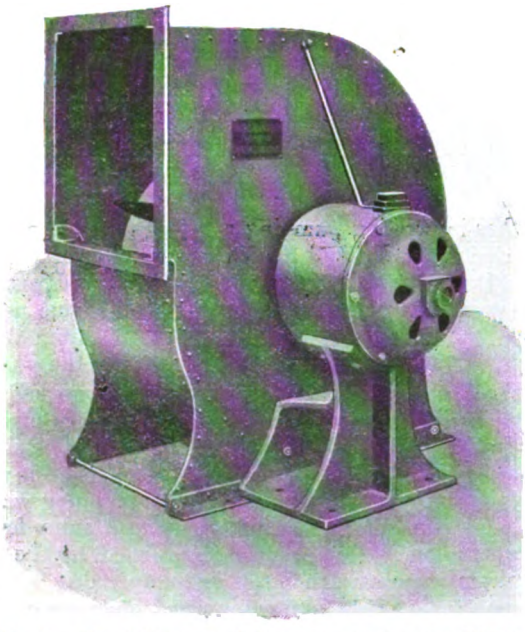

FIG. 2.—THE "CYCLONE" BLOWER FOR MARINE WORK.

This firm make two types of fans, viz., the open propeller and the cased or centrifugal, the former being used when it is possible to get a free outlet and the latter where it is necessary to overcome the resistance of ducts, &c. Both types are fitted with the firm's high-class motors, now so widely known. They are compact, liberally designed and of sound construction, the parts being interchangeable and both armature and coils are former wound. The fans themselves are the outcome of years of experience and are guaranteed to be equal in efficiency and output to any on the market; in fact, the makers claim that the power consumed is less than any other make for a given output.

The "Cyclone" blower and exhauster is, it is claimed, the exact thing for the ventilation of the stokehold, or for cooling the engine room, and this particular type of fan can also be adapted for supplying draught to the boilers. Mechanical draught is now being adopted largely for marine work, both on the forced and induced principles. The former is accomplished by delivering a pressure of air under the ashpit and the latter by fixing a fan on the funnel side of the boilers, which draws the hot gases through the furnaces, and also increases the draught in the grate bars, &c. With the increased draught a greater quantity of fuel can be consumed on the same grate area and a greater heat obtained. This, transmitted to the boiler furnace, increases the capacity of the latter by raising more steam in a given time, and, in addition, renders the amount raised independent of the funnel.

An additional advantage obtained from the use of mechanical draught is the abolition of black smoke; this is prevented by the correct amount of oxygen being drawn through the fires, and combining with the carbon at the proper temperature. Seeing that black smoke is due to incomplete combustion, a saving is thereby effected.

Electrical Resistance Thermometers for Cold Stores.

The importance of keeping a careful watch over the temperature in cold storage chambers is evident to all. In some large stores a man is employed whose sole duty it is to read and keep a record of the temperatures of the various thermometers distributed over the buildings. If ordinary thermometers are used this necessitates the opening and shutting of a large number of doors, which, in addition to the labour cost, is very wasteful of power, and tends to destroy the uniformity of temperature of the various rooms. By the installation of electrical resistance thermometers, however, the temperatures of all the rooms may be ascertained by the engineer in the engine room in a very few minutes.

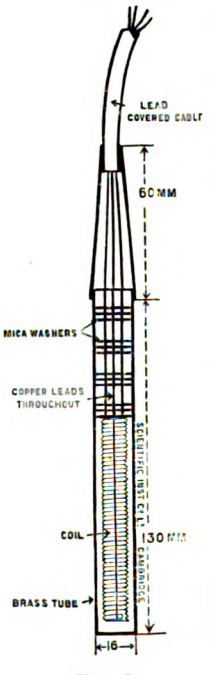

FIG. 1.

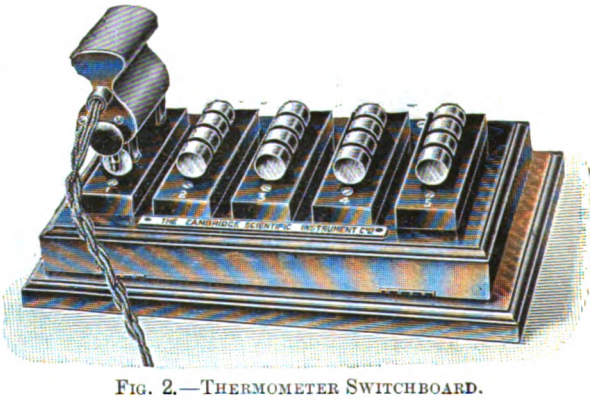

FIG. 2.—THERMOMETER SWITCHBOARD.

The Cambridge Scientific Instrument Co., who supply electrical thermometers and pyrometers of many patterns, have also developed a special design for use in cold stores. These work on the Wheatstone's bridge principle, the indicator (Prof. Callendar's patent) being a combination of a galvanometer with a bridge of the Callendar and Griffiths' type. A

number of outfits similar to that described below have been installed by the Company at docks and other places; and a modified design for use on board ship is to be placed on the market in the near future.

A four-way lead-covered cable runs from the indicator to the thermometer, two of the wires being connected to the resistance coil of the thermometer, whilst the other two are "compensating leads." These latter are connected to the bridge so as to neutralise the effect of the other two wires, and so render the reading of the indicator entirely independent of the length of the leads or of changes in their temperature. As the resistance of the thermometer changes with the temperature, the galvanometer is deflected. This deflection can be brought back to zero by moving the galvanometer contact point on the slide wire of the bridge. The position of the contact point may, therefore, be calibrated to indicate directly the temperature of the thermometer. Leads are run from the refrigerating rooms to the engine room, and connected to a switchboard (Fig. 2). By means of a plug connection is made from any of the thermometers to the indicator. An electrical resistance thermometer suitable for use in cold stores is shown diagrammatically in Fig. 1. Being enclosed in a brass tube it is readily responsive to changes of temperature and practically unbreakable.

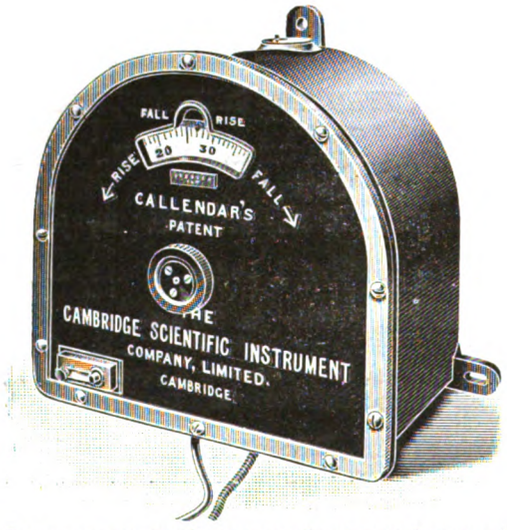

FIG. 3.—INDICATOR OF THE CAMBRIDGE SCIENTIFIC INSTRUMENT CO.

The indicator illustrated in Fig. 3 is fixed on the wall near the switchboard. It is enclosed in a cast-iron case, on the face of which are placed a key and handle. When the key is pressed, if the galvanometer needle (seen at the top of the window) is deflected either way from the zero position, the handle is turned in the direction opposite to that of the needle's deflection, until the needle arrives at the zero. This shows that the bridge is balanced and the temperature of the thermometer can then be read directly from the dial. A small battery of dry cells completes the equipment.

As mentioned above, the Cambridge Scientific Instrument Co. have fitted up several large cold stores with thermometer outfits of this type. In one case, where 34 thermometers were installed with one indicator and switchboard, it was found that the temperatures of all the rooms could be read in 10 minutes. Before this installation was adopted the same operation took 55 minutes. As the readings are taken eight times in the 24 hours, the time saved amounts to six hours per day. In the majority of cases, therefore, an installation will more than pay for itself in 12 months.

A very complete system of electrical thermometry, known as the "Telethermometer," has been worked out by Messrs. Nalder Bros. & Thompson, Ltd. This system was originally suggested by Mr. A. B. Chatwood. Whilst being generally applicable to measuring temperatures under various conditions, it has been especially designed for use in cold stores and in vessels carrying refrigerated produce, and has proved very useful in magazines and coal bunkers on board ship. It is perfectly simple in operation, needing no technical skill or knowledge whatever, all that is required to be done being to turn a handle (or press a button) and read the dial.

Amongst many advantages connected with the use of this system on board ship is that thermometer tubes from the holds to the deck may be entirely done away with, which is a great advantage, inasmuch as there is no interference with the cargo, and no risk of carrying water from deck into the holds. All the thermometers in the ship can be read from one central point, and this point may be anywhere that is convenient, such as the engineer's cabin. Also, as each thermometer is never

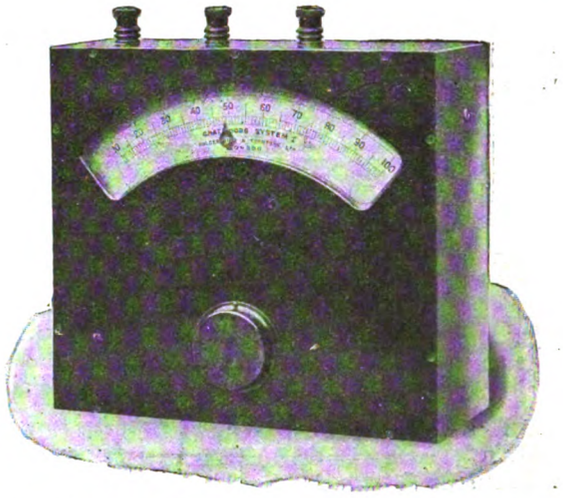

FIG. 4.—INDICATING INSTRUMENT OF MESSRS. NALDER BROS. & THOMPSON.

moved from its position, the results obtained must be far more accurate than where the thermometer has to be moved in order to read it.

Fig. 4 shows the indicating instrument; this is mounted in a polished wood or cast-iron case, and is of the moving coil type. An electrical resistance thermometer is used, mounted in a hollow metal tube, as shown in Fig. 5, thus ensuring a quick response to any change of temperature. From each of these tubes a lead-covered cable of suitable diameter is run to a distributing switch and the indicating instrument. A hand magneto is provided as a reserve in case there should be a breakdown in the electric lighting system, and excepting under this circumstance the apparatus is worked from the lighting mains. The actual pressure required is about 30 volts continuous current, and a resistance is provided to enable the correct voltage to be applied to the terminals of the instrument.

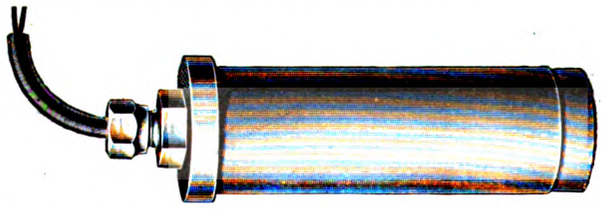

FIG. 5.—ELECTRICAL THERMOMETER OF MESSRS. NALDER BROS. & THOMPSON.

The features claimed by Messrs. Nalder Bros. & Thompson for this system are its great simplicity and the speed with which the temperature at a large number of different points can be measured.

In practical resistance thermometry it is a great advantage to use an indicator reading directly in air scale temperatures by the movement of a pointer over a dial, rather than to have to balance a galvanometer to zero and take the reading from the balancing resistance. The latter method renders it impossible to watch a varying temperature without constant manipulation, and it is always desirable to avoid this in commercial measuring appliances. In our issue of December 25, 1908, we briefly described an instrument for effecting this, namely the

Harris resistance thermometer indicator, shown by Mr. Robt. W. Paul at the Physical Society's annual exhibition of apparatus. Since then improvements have been effected in the construction, and a full scale deflection can now be obtained for a variation of 50°C. or less, in the temperature of a platinum thermometer of 1 ohm fundamental interval, employing an indicator with a balanced movement suitable for use at sea.

The indicator is constructed upon the principle of the differential galvanometer with an electrical control. One of the differential windings (X in Fig. 6) is shunted with a platinum thermometer, the other winding, S, being shunted with a

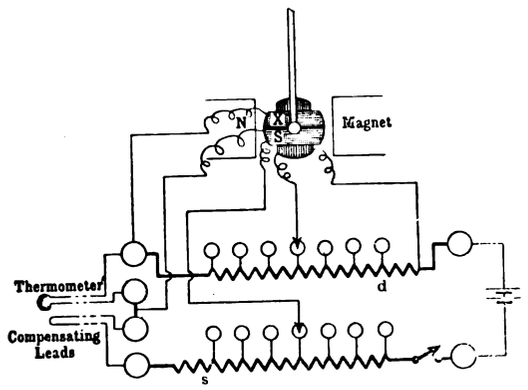

FIG. 6.—DIAGRAM SHOWING ELECTRICAL THERMOMETER CONNECTIONS.

resistance *s*, which is made variable so as to equal the resistance of the thermometer at certain fixed temperatures. The control coil of the ohmmeter system is also shunted with the resistance *d*, the value of which is determined by the degree of sensitiveness required, and may be made variable with *s*. These shunted windings are connected in series, and the circuit is completed through a battery and switch. By using a differential winding (the currents in which are respectively due to the resistances of the thermometer and *s*) in conjunction with a control coil (in which the current is proportional to a selected difference unit *d*), the advantage is gained of making the indicator read on both sides of what would be the zero point

FIG. 7.—ELECTRICAL THERMOMETER BY R. W. PAUL.

in an ohmmeter of the usual construction, thus increasing the open length of the scale from about 45 deg. of arc to more than a right angle. Moreover, as the deflection is proportional to the ratio of the *diffe ence* of the currents in the differential windings to the current in the control coil, the sensitiveness for a given variation in the temperature of the thermometer may be made as large as desired by giving a suitable value to *d*, and is only limited by practical considerations.

The instrument, which is illustrated in Fig. 7, may be constructed to cover a full range of temperatures up to 1,200°C. By means of a switch the range covered by the deflections may be moved along the temperature scale, *e.g.*, an instrument covering by deflection, say, 200°C. may be set to read from 0–200°C., 200–400°C., &c., at will; and when so constructed the movement of the switch simultaneously varies *d*, thus automatically compensating for the decreased change of the resistance of the thermometer at higher temperatures and maintaining the accuracy of the readings on the air scale.

It is not to be expected that an instrument reading by deflection will attain the high scientific accuracy of null methods. The first commercial instrument of this type made up, however, showed a quite remarkable accuracy, which was confirmed by tests made at the National Physical Laboratory, where the error was found in no case to exceed one-third of 1 per cent. At the National Physical Laboratory the errors, with a 4-volt accumulator whose E.M.F. was 4·2 volts, were found to be as follows :—

Temperature (degrees).	Error.
0·0	0·0
100·0	0·0
203·1	−0·1
420·2	−0·2
779·4	+0·8
1,196·9	−1·9

To study the effect of the measuring current, a series of readings were taken with a secondary battery, whose E.M.F. was only 3·7 volts, and also with the 100-volt lighting circuit mains with 1,000 ohms in series.

True air temperature.	Readings of indicator. Battery E.M.F. 4·2 volts.	Battery E.M.F. 3·7 volts.	100-volt lighting circuit.
100·0	100·0	100·0	100·0
654·4	656·0	656·0	656·0
1,196·9	1,195·0	1,198·5	1,197·0

A calibration of the scale was made for every 20 deg. for the range 200°C.

Indicator reading	0·0	19·8	39·3	59·4	79·4	100·0	120·5	140·8
Error	0·0	0·0	−0·3	−0·2	−0·3	−0·0	+0·1	−0·1
Indicator reading				161·4		182·0		203·0
Error				−0·1		−0·2		−0·1

It will be noted that the instrument is practically independent of the applied voltage within the range of charge and discharge of a 4-volt accumulator battery. Where available, current may be taken from the direct-current electric light mains by using a resistance, usually about 10 ohms per volt, in series with the indicator.

The thermometers for use with these indicators are provided with the Callendar & Griffiths compensating loop, and are brought to a standard resistance by means of a series coil of negligible resistance, in the head of the mount, thus securing electrical interchangeability without the necessity of using any adjusting or compensating device.

Capstan and Other Controllers.

The conditions under which electric power is employed on ships, docks and wharf sides differ materially from those which are presented in industrial service. Not the least important element to be considered is that of labour. The average man in charge of a capstan or ship's winch has no respect for things terrestrial. If the machinery under his control cannot perform its functions in the particular manner which he himself prescribes, then the sooner it is broken up the better. Further, the loading or unloading of a ship is not a matter into which the technical refinements of motor control can possibly be made to enter. Affairs maritime are usually conducted on the "get-there-somehow" principle. Electrical apparatus must accordingly expect the same ruthless treatment at the hands of the men as is served out to steam machinery.

The manufacturer of motor control gear must have these important facts in mind. His products must, as nearly as possible, meet the previously existing conditions, and be cabable of exactly similar treatment.

Digitized by Google

The Adams Manufacturing Co. have been paying special attention to the subject of electric control for shipboard work. They have devoted considerable time and energy to the apparatus, they have produced some excellent pieces of apparatus for mercantile and passenger service.

A drum type controller which possesses some novel and

same operations. It is instructive to compare the operations of a steam engine with the electric motor on, say, a heavy cargo winch.

It is a common occurrence for the engine or motor, as the case may be, to be overloaded until it stops. The steam engine is able to meet this condition easily, for it just comes to rest with steam behind the piston waiting for the load to go off. With the ordinary electrical control, however, the over-load opens the circuit breaker, which has to be re-set before starting again. This continual opening of the circuit breaker has been a source of annoyance and weakness in the electrical drive, and the Adams controller has been designed to avoid this.

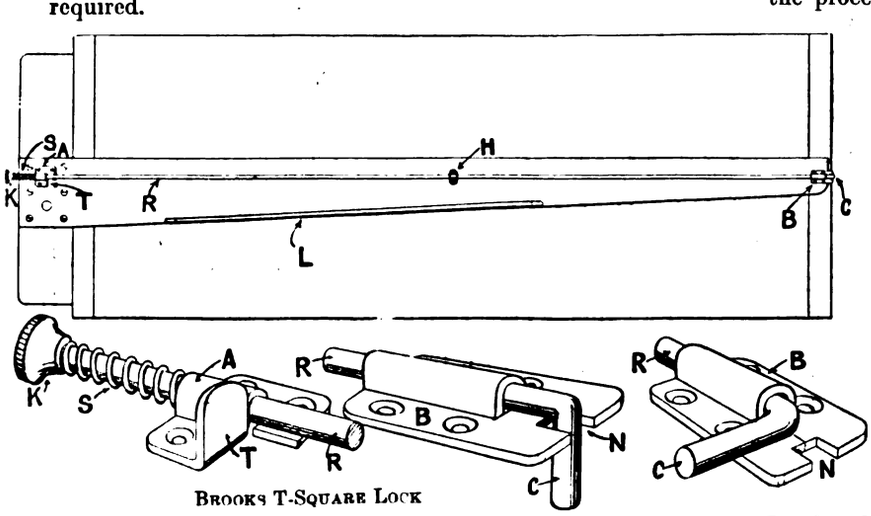
Fig. 2 shows the massive design of the controller, which gives a watertight construction, possessing great strength. The internal parts are shown in Fig. 1. They consist of the ordinary drum contacts and fingers for starting and speed control of the motor, but with the addition of two Igranic patented magnetically operated clapper switches or circuit breakers fitted with no-voltage and overload release.

With this construction, when a heavy overload comes on the motor, the clapper switches "trip" and open the circuit of the motor, bringing it to rest, the load being sustained either by a solenoid brake, or by the latest electrical resistance method. Then, to re-start the winch when the overload is taken off, it is only necessary to bring the handle back to the starting position to re-set automatically the clapper switches and start as before.

Another special Adams product for shipboard use, is a patented sea-going resistance. A bank of these resistances is shown in Fig. 3, and the essential feature of these units is that only iron, mica, and resistance alloy are used in their construction, so that there is nothing to deteriorate. The resistances can be momentarily overloaded to red heat without damage, and the complete resistance is a much stronger and more compact and at the same time a lighter unit than the ordinary grid type.

Brooks T-Square Lock.

An interesting piece of apparatus, which has been designed by Messrs. W. J. Brooks & Co., for drawing office work is the T-square lock. This is a simple device which can be attached to any ordinary T-square, enabling the latter to be locked in any position on the drawing board, thus setting both hands free to manipulate the set square. The arrangement does not, however, prevent the T-square being easily shifted when required.

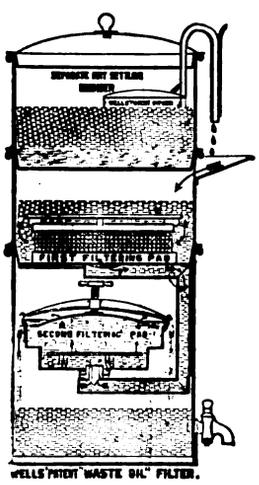


BROOKS T-SQUARE LOCK

The device consists of a thin steel rod extending the whole length of the T-square blade and sliding in bearing plates at each end. These plates are screwed to the blade and stock respectively. One end is bent at right angles to form a claw and the other terminates in a knob. A helical spring bears against this knob and presses the rod to the left, which causes the claw to bear against the right hand edge of the board and to pull the stock of the T-square firmly against the other edge and thus prevent it slipping down. Both hands are thus set free. To shift the T-square the stock is grasped with the left hand, the thumb pressing against the thumb piece and the fore finger pressing the knob to the right. This causes the claw to stand slightly away from the edge of the board, permitting the T-square to be moved by the left hand alone with precisely the same freedom as if no attachment was there. On releasing the pressure on the knob the T-square again becomes locked.

Wells' Waste Oil Filters.

On shipboard it is not expedient to carry any more of one commodity than is absolutely necessary. The space available is so small that "cutting" in all possible directions is necessary to obtain comfort for the personnel. We are not, therefore, surprised to find that oil filters are extensively used in connection with the machinery employed on shipboard, for both an economy in oil consumption and a less space for storage become possible by their use. Messrs. A. C. Wells & Co. make a very efficient filter for this purpose, a section of which we give herewith. The method of operation is sufficiently clear from the illustration. The construction is of the simplest, all parts being easily accessible for cleaning. The filtering pads can be quickly and cheaply renewed. The new patent sight-feed syphons, which are also supplied on the larger sizes, are a valuable addition, as by this method the best surface of the oil only is syphoned over to the filtering pads, giving time for the dirt and water to settle naturally to the bottom of the collecting chamber.



SECTION OF WELLS OIL FILTER.

Mirrors for Searchlights.

The Cowper-Coles process for the formation of mirrors by electro-deposition is now well known, so that a description of the process is unnecessary; it may be mentioned, however, that the Reflector Syndicate (Ltd.), who operate the Cowper-Coles patents in all the principal countries of the world, have recently introduced gold deposited mirrors for searchlights.

Light reflected from a gold-coloured reflector is found to illuminate a distant object more clearly and to be more penetrating in thick and foggy weather, the probable r ason for this being that the beam from a gold reflector contains a very high percentage of red and yellow rays, which are least absorbed by the atmosphere. Another advantage of gold mirror rays is the absence of white halos and consequent deep shadows of objects close to the source of light; in other words, there is a softer and more even illumination of fore and background. It has also been found easier to distinguish colours which are very similar. For instance, a grey object, such as a torpedo boat on a grey sea with a grey sky, is more clearly seen with the gold than with the silver mirror. Lastly, the gold, unlike the silver deposit, is unaffected by chemical or climatic conditions, so that the reflective surface remains highly efficient. This is a distinct advantage for heliograph work, for in damp and tropical countries the silver mirror rapidly deteriorates. These gold-deposited mirrors should, therefore, prove of considerable advantage in marine work.

"KALKOS"

TRADE MARK

TINNED BRASS TUBE SYSTEM

. . for all . .

Ship Wiring Installations.

For the Wiring of Ships of every kind, from the largest Atlantic liner to the smallest pleasure craft, the "Kalkos" system has come to be regarded as the *sine qua non* of good engineering practice. The fact that it is equally suitable for

Concentric, Twin, or Three-Wire systems,
Semi-flush, Flush, or Surface Installations

enables any or all systems of distribution and installation to be employed. With the "Kalkos" system

No Condensation or Corrosion Troubles

are ever experienced, and to substantiate this claim all "Kalkos" Conduits and Fittings sold are accompanied by a three years'

Guarantee against failure or breakdown of Wires

due to condensation or corrosion. There are many other advantages to be found in the "Kalkos" system, foremost among which are

- ¶ **Ease of erection and neatness for surface work.**
- ¶ **Perfect metallic continuity of low resistance.**
- ¶ **It is watertight and practically airtight.**
- ¶ **It is extensively used for the lighting of steamships and pleasure yachts of every kind.**

Write TO-DAY for the "Kalkos" List, Section K.

THE EFFECT OF FREE TRADE OR PROTECTION UPON THE ELECTRICAL INDUSTRY.

At the adjourned meeting of the National Electrical Manufacturers' Association, which was held on Monday last, at Caxton Hall, the very interesting discussion on the above subject was continued. An account of this is given below :—

Mr. E. GARCKE, in opening the adjourned discussion, called attention to the fact that what Sir Alfred Bateman, the Comptroller-General of the Commercial, Labour and Statistical Department of the Board of Trade, said in 1902 applied with very great force at the present time, viz., that we were still ahead of Germany and the United States in our power of manufacture for export. But, beginning from a lower level, other countries were travelling upwards more rapidly than we were to get a higher eminence. If peace were maintained, both Germany and the United States were certain to increase their rate of upward movement, and their competition with us in neutral markets would probably become increasingly serious every year. It was necessary, therefore, more than ever, that a change of condition should be recognised, and we could scarcely expect to maintain our pre-eminence without strenuous efforts and careful and energetic improvement in method. Sir Alfred Bateman could not be accused of being a Tariff Reformer. As an official of the Board of Trade he spoke without bias. What was the position at the present time ? For some years past the rate of unemployment in England had been approximately double that in Germany. All nations had suffered in National credit, but England had suffered in a larger ratio than any other countries. Emigration, which was an important factor, was greater from England than from other countries. Those were the conditions that had to be dealt with at the present time in this country. They, however, had met, not to solve the problem of unemployment, but to consider the alternative fiscal systems of Tariff Reform and Free Trade. He wished, first of all, to point out that their views were not diametrically opposed. There was a basis for an arrangement, and he thought he could not do better than to make a general statement of the points of divergence. His argument was that Free Trade and Tariff Reform were very much interwoven in every country and even in every individual. Everyone wanted to have Free Trade in regard to the commodities he purchased, and yet to be a Protectionist in regard to his manufactures. That could not be better exemplified than by referring to the English Labour Party. There was no more protectionist body in the world than our trade unions. It was because the arguments had been so ably expounded by economists that so many educated men were Free Traders at the present time. Moreover, England had enjoyed a period of exceptional prosperity concurrently with the practice of Free Trade. As Mr. Hirst pointed out at the last meeting, it had not been by the aid of Free Trade, but in spite of it. Mr. Cowan had stated that we had too much competition and that it should be regulated. Would Mr. Kingsbury, in reply, say how competition could be regulated, so far as foreigners were concerned, except by means of a tariff ? By referring to the writings of economists one would find that what they meant by Free Trade was free exchange of commodities, and no one could doubt that that between all nations was an ideal system of trade ; but, unfortunately, we had never had that system, and the world did not appear ready for it, any more than for universal peace. We might not need tariffs, but we must have them because other countries had them. Again, the Free Trade statement that exports were balanced by imports was nothing more than a fallacy. It was exactly the same as the book-keeper's phrase that "every credit has a debit," but no accountant would be so foolish as to carry that argument to the other extreme, that every loss was balanced by a profit. The effect of the policy of Free Trade was that our profits were being gradually eliminated. He did not agree with Mr. Kingsbury that our ability to buy in the cheapest market increased efficiency, if we also had to sell in the cheapest market. The principle of all economists was "buy in the cheapest market and sell in the dearest market," but they could not do that. We made no profit on our considerable turnover because our imports from abroad decreased the prices of our own productions, which, as shown by Mr. Hirst, cost us more to produce. Free Traders said that reduction of price was a benefit to the consumer and they stated that we were all consumers and therefore everyone benefited ; but the argument overlooked the obvious fact that no country could consist of consumers alone and that in the end all consumers were dependent upon the producers. Free Traders were defeating their own objects. They were encouraging the formation of trusts and monopolies abroad which tended to destroy all freedom of exchange in commodities, and in course of time they would control our markets and we should be at their mercy in regard to prices. They would be told that the foreigner would not be so absurd as to destroy a good customer, and we were bound to send out some goods in order to buy. As a result of the prosperous period we had enjoyed, we had amassed very considerable wealth, and whether we were producers in the future or producing at a profit now we should for some time to come be able to purchase largely from other countries. Until that time came, foreigners would not worry themselves by what means their good customer was maintained for the future. Meanwhile, we were getting feebler and poorer. At present our exports of home produce to France, Belgium, Germany and the United States (our principal competitors) were less than half our imports from those countries. That was not all. Nothing had been said about imperial preference and keeping hold of our colonial trade. He therefore referred to an account of the Congress of the Chambers of Commerce in Australia, in which the Commonwealth Minister for Trade and Commerce said that Australia found, with grave misgivings, that her trade with Great Britain was decreasing, and that she was becoming more and more dependent upon foreign countries. Had Great Britain retained the proportion of Australian trade which she possessed in 1880 she would have exported to Australia in 1908 £10,000,000 worth more goods than she actually did. Mr. Garcke finally appealed to them not to discuss the question on political lines.

Mr. H. OPPENHEIMER thought that both Mr. Garcke and Mr. Hirst, in their endeavours to show that the electrical industry was suffering under Free Trade, had failed to produce a single argument which supported their opinion. Mr. Hirst, in asking why it was that since 1881 we had lost the supremacy we held then, should have told them that at that period events were happening on the Continent, especially in Germany—and he laid stress on that point, because during the whole discussion they had not once heard an argument relating to France ; it was invariably Germany which took the foremost place. Germany, before the creation of the Zoll Verein, was industrially no power whatever, and other countries at the time began to find out that they could do something and that the only country which was doing anything was England. In 1887—the time of our greatest distress—no one knew where our supplies came from. An attempt at so-called Protection was made in order to guard against the possibility of foreign-made goods being mistaken for English goods. The result was that we gave the most extensive and expensive free advertisement to the Continent. The electrical industry was not what it should be. It was ill and suffering in spite of Free Trade, but it would be ill beyond recovery if Tariff Reform were ever to come to its rescue.

Mr. G. BYNG thought the most important statement in Mr. Kingsbury's address was where he referred to the cost of production and in which he said that Free Trade gave us advantages for cheap production. Mr. Kingsbury said that under Protection the cost of production would increase. Mr. Byng joined issue with him and challenged him to produce one single proof. The first factor for production was material. He was acquainted with a great many industries and he had never found Mr. Kingsbury's statement to be true. For example, in the electrical industry. Did he get his copper, iron, platinum, &c., to any degree cheaper than his competitors in New York, Berlin or Paris ? His experience was that he did not. Another point : it was said that under Free Trade one got cheap food and therefore cheap labour. It was well to be clear upon those points, and to understand the attitude of Free Traders upon the question of wages. They talked about cheap production and cheap labour, and then on the political platform they said that under Free Trade wages were much higher than in protected countries. They could not have it both ways. The truth was that wages must come down under Free Trade. It was impossible for our workmen to allow the whole world to compete with them—nations where wages were very low—without themselves in the long run coming down to the level of those nations. Again, low wages did not necessarily mean cheap goods. When machinery was now used for every sort of production the experienced manufacturer knew that he got the best return from his machinery if he used the best-paid labour. It was not only labour and material which made up the cost of production, but there were other equally potent factors that went towards cheapness of production, such as skill, invention, and above all the quantity manufactured. In all those factors the protected foreign manufacturer had immense advantages. No new industry could be established under Free Trade and no industry could grow under Free Trade. We were not a free country : it was the foreign manufacturer who had got to say whether an English industry was to exist or not. Free Trade meant dear production, and dear production meant decay and ruin.

Mr. R. HAMMOND found it was acknowledged that they could not protect their industry without protecting some others. He was glad to find that the object of the meeting was to discuss the question whether Free Trade or Protection was best for England, and not to see whether they could get protection for the electrical industry alone. He dwelt upon that point, because England stood in a unique position. It possessed 44 million people on an area that would only grow food for half of them. Mr. Garcke seemed to be very well acquainted with 60 years ago. For him, the speaker, England was the living England of to-day. Food stuffs to the extent of 242 millions came into this country last year. There were some people who thought that instead of covering our ground with Osram works we should grow wheat everywhere. If they did that what would become of our manufacturing supremacy ? England was no country for growing corn. At the beginning of the controversy it was said that we poured our gold from England, but he was pleased to hear that last year we received 6½ millions more gold than we paid out. Some people said we paid in securities, but that also was not correct. The only way to pay was by our manufactures. Everything was paid for in cheques. There was no reason why exports should be paid for by imports. Thus, Free Trade England, to the extent of all its exports, competing with the world, proved to Mr. Byng that we could beat the world in price and quality. The instant imports were kept out the exports would fall off and our power of competing with the world in open markets would suffer accordingly.

Mr. H. H. BERRY doubted whether Mr. Hammond had ever manufactured anything in his life in this country.

Mr. R. HAMMOND, interrupting, said that he was a manufacturer for a good many years.

Mr. BERRY, continuing, said that without our manufacturing industries we could be nothing but a body of importers. He wished to introduce himself as an unfortunate example of the effect of Free Trade on the

Digitized by Google

electrical industry. If, in later days, he had achieved any slight financial success it was entirely due to the fact, in spite of Free Trade, that he had found his own protection in the medium of the Patent Office. He thought Mr. Kingsbury's remarks that in the electrical industry our Free Trade policy had enabled us to apply at once any advance elsewhere and to give the industry a start on the most practical lines, and as soon as the demand became large enough we abandoned imports and manufactured ourselves, thus obtaining the benefits of successful improvements at a small cost, whereas Protection would have delayed us for years and enormously increased the cost, were ridiculous. Take lampholders, for example. The foreigner actually came in and took our speciality and supplied it to the extent of 80 per cent. Free Traders would not see that they were fighting on unequal terms. What were our Continental friends doing? They sent us Mr. Oppenheimer to come on the platform to confuse the issue by talking about hay.

Mr. W. G. Bond mentioned some Board of Trade figures, from which it seemed that in seven years, since 1902, this dying country increased its trade by 19 per cent. Mr. Garcke said we were making no profits. Official figures again showed that our profits had gone up from 487 millions to 508 millions, which was about 5 per cent.

Mr. Garcke asked if that was per year.

Mr. Bond said he was taking the figures for 1902 against 1908. Again, Mr. Garcke seemed to think that it was very wrong to import. If he would look at the figures for a long term of years he would find that the years of greatest imports coincided with what were known as "boom" years. Assuming that imports were all wrong and that exports were the thing, he would refer to figures for 1908. The English exports per head were £9. 10s., compared with £5. 8s. in Germany. He thought that a large number of speakers on the Protectionist side believed that a Protectionist Government would get a scientific tariff absolutely adapted to the needs of each individual industry. Did anyone mean to say that what happened in Washington a few months ago was scientific taxation for each industry? It was the industry with the largest price that got the biggest slice. The electrical industry was poor and would come off worst. He asserted, without fear of contradiction, that they could not protect any sensible proportion of the people of this country. If higher wages were to be paid under Protection, then how could the cost of production be kept down. Apart from their own industry, how were they going to protect shop-girls, &c. In conclusion, Mr. Bond quoted from an English contemporary "that in every country it always was and must be the interest of the great body of the people to buy whatever they wanted of those who sold it cheapest." The proposition was so very manifest that it seemed ridiculous to take the pains to prove it.

Mr. A. Bruce Anderson agreed with Mr. Hirst's remarks. The only point on which he could agree with Mr. Kingsbury was that he wished it were possible to get a more reasonable attitude on the question of foreign trade. The meeting was called for the purpose of discussing the effect of the fiscal policy of the country upon the electrical industry; Mr. Kingsbury accepted the invitation to expound the Free Trade point of view, but made no attempt to do so from the very outset. He said that one must look at the good of the nation as a whole and therein one would find the good of the electrical industry. It had been said that no man could be a good citizen of the world who was not a good citizen to his own country. He (Mr. Anderson) would go further and say that no man could be a good citizen of his own country who was not a good citizen of his own industry. If the interests of the electrical industry and the nation as a whole were identical under Free Trade it was extraordinary that a man of Mr. Kingsbury's long and wide experience in the electrical industry was unable to produce one single practical illustration of where they coincided. Unemployment in this country was now greater than in any other country, from which we had returns. The only returns we had, however, were trade union returns. Trade unions numbered only one-tenth of our working population. Amongst the other nine-tenths unemployment was appalling, and on the top of that we had 12 millions of people living on the borders of starvation, and on the top of that again we had exported during the last two years over two millions of our workmen. If those were the conditions necessary for the completion of our wealth then, he said, let us get poorer. As Tariff Reformers, what they agitated for was a fairer field against their foreign competitors. When that fair field was obtained they would not be afraid of the result.

Mr. J. E. Kingsbury, in replying for Free Trade, said that the tendency of the speakers had been to depart from the line upon which they started their discussion, and they had brought in all sorts of side issues, such as Mr. Anderson's. Mr. Anderson surely knew that unemployment was not a matter which depended upon Free Trade or could be cured by Protection. It was a social question which required the most careful investigation; and a Tariff Reformer who said that Tariff Reform meant work for all was taking a very narrow view of the question. Mr. Garcke had said that the idea of Free Traders that imports were paid for by exports was all wrong. Free Traders did not all say that imports were specifically paid for by some definite export. In reply to Mr. Garcke's question as to how competition could be regulated except by means of a tariff, he (Mr. Kingsbury) said that to regulate competition was a very difficult thing, but to be prepared for competition was an easy matter. All that one had to do in order to be able to compete was to be efficient. Mr. Garcke said we did not sell to certain countries as much as we bought from them. Did any of them buy as much from the man they sold to as they sold to him? Of course they did not, nor need we as a country. Mr. Byng had asked what materials he could buy more cheaply than his competitors in a foreign country? If Mr. Byng had given him notice of that question, he could have given him a pretty long list. Mr. Byng could buy his copper wire cheaper at home than his competitor in Paris and he could buy his lead £5.16s.8d. in London cheaper than his American competitor.

Mr. Byng remarked that he did not say copper wire. This was a manufactured article.

Mr. Kingsbury, continuing, said that unless Mr. Byng drew his own wire the value of the price of copper was nothing to him. His raw material was copper wire. At the last meeting, Mr. Raworth told them that 90 per cent. of the tramway material came from America. He (the speaker) was startled by that, and asked some friends of his whom he considered likely to know what they thought it would be. They gave him a very modest figure, and one said it could not exceed 5 per cent. They would see that there was a wide discrepancy between the two figures, but he had information which he believed to be precise, viz., that in a large tramway system constructed within the last 10 years there was not a particle of electrical material from abroad. England could supply all the tramway material that was required. Mr. Raworth had told them about some friends of his who subscribed capital and had it returned in the early days. This was due to an ill-considered Act, but had nothing to do with Free Trade.

If there was one thing in the world that he (Mr. Kingsbury) did not know anything about, it was cotton, and he did not think Mr. Hirst knew much more. He (Mr. Hirst) was quite concerned about the cotton industry and was anxious as to whether it was in a quite healthy state, and he somewhat unwisely considered that the cotton industry and the electrical industry were not just on parallel lines as they should be. He (the speaker) had no doubt that the electrical driving of cotton mills was bound to come. He also had no doubt—Mr. Raworth had told them so—that the Lancashire men knew their business, but he believed electrical driving in cotton mills would come the sooner if they treated the manufacturer of Lancashire as if he did know his own business. Mr. Garcke talked about Free Trade as a religion. He was not there to speak about religion, but to talk business. How were they to deal with any question of business that did not first of all take into account facts, then deductions from those facts and arguments on those facts. That was what he was going to do, and with a view to reaching that conclusion he was going to examine Mr. Hirst's facts, his arguments and deductions. As to history, he would like to know why 1880 was selected as an epoch-making year in the history of English commerce. Our business was in a sound condition in 1880 and as sound to-day as ever it was. Mr. Hirst then touched on what might be called the depreciation of Free Trade, and told us that our prosperity was not due to Free Trade. It so happened, said Mr. Hirst, that the introduction of Free Trade in this country tallied with the developments of steam as a power to reduce the cost of production, and Mr. Hirst implied that the progress resulted from steam and in spite of Free Trade. Was it not reasonable to say when one found that Free Trade and steam ran along parallel lines that the development of the steam resulted from the freedom of the trade, rather than that the freedom of trade acted as a bar to the full development of the steam? Mr. Bennett Fitch told them that the hunger of the forties was not due to the scarcity of food, but to the superabundance of machinery. In reply he would read an extract from "The Times" of the last day of the year 1853. [This extract refered to the scarcity of corn as being the result of Protection.] It was important that it should be realised that the workman had no need to fear labour-saving machinery. History told them that every machine which reduced work had increased production and employment. Such methods of promoting Protection could do nothing but harm to the cause.

Mr. Hirst had told them that nearly every electrical invention up to 1884 originated in this country. That was a pretty wide statement, but surely it was not presumed to cover the whole ground. The telephone, the accumulator and Gramme's dynamo were notable exceptions. The first arc lamps that were installed here bore the names of Jablochkoff and Rapieff. Those were followed by the Lontin, Werdermann brush, the Pilson and so on. Did France and Russia trouble us now? If not, was it because Russia and France had Free Trade? The fact was that the English contribution to the arc lamp development was more important in the fifties than in the early eighties. There was not a single statement in Mr. Hirst's remarks regarding the electrical industry which was not either incorrect in itself or might reasonably be read in an incorrect way.

Turning to the question of general engineering, American literature did not support the idea that our rail mills were losing ground. Mr. Hirst asked why a manufacturer in protected countries could produce in larger quantities? It stood to reason, Mr. Hirst said, that a manufacturer who had a market of 60 million of inhabitants sending to them must be better off than anybody else. If that be a fact, had they not better put up the shutters, because one must not overlook the fact that our population would not permit us to complete on such terms. We had 40 millions and America had double; how could we manufacture as cheaply as America? It did not stand to any such reason. If it did, why did America have any imports at all? In 1907 they imported £209,000,000 worth, of which £133,000,000 were manufactures. The manufactured article in quantities involved the expenditure of capital, which was dependent upon the quantity required. Mr. Hirst said that with his proposed 10 per cent. protection on lamps, no one would be a penny the worse, but he (the speaker) undertook to say that nobody would be a penny the better. What was got with one hand would be lost with the other. The prime factor in determining cost price, said Mr. Hirst, was the quantity that could be produced. This the speaker regarded as emphasising the variable condition and omitting entirely

Digitized by Google

the vital and invariable conditions, such as the costs of materials, food, clothing, house rent, and all the amenities that went to make up existence. He gave examples of exports which the "aims and ideals of Tariff Reformers," as expounded by Mr. Hirst, would interfere with, and alluded to the detrimental effect which the loss of such manufactures must necessarily produce on the electrical industry.

Mr. H. HIRST, in replying for Protection, thanked his supporters for having brought such interesting matter forward with such fervour and conviction. He more particularly recommended to their earnest consideration the interesting contributions of Mr. Garcke and Mr. Bruce Anderson, with whom he was in full accord. Passing to other points, he congratulated Mr. Hammond on his humorous rendering of his contribution to the debate, but he would remind him that his (Mr. Hammond's) experiences as a producer dated back 30 years. When Mr. Hammond spoke of the 242 million pounds worth of corn that we imported he could only reply that if we produced in this country all the corn that this country is capable of producing—say fifty million pounds worth or more—we could obtain the balance that we wanted at a very much cheaper rate. The present prices ruling in England were fixed, in the opinion of the speaker, irrespective of the cost of production or of supply and demand, but were largely based on the helplessness of this country as a non-producing nation, for we must have wheat at any price. The prices for too many commodities that were regulated by supply and demand in Protected countries were fixed in conference by foreign producers for the buyers in a so-called Free Trade country. Mr. Bond had suggested that Protection might be good for the manufacturer or industrial worker, but asked what about the working man in the building trades, printing trades, professional men, postmen, schoolmasters, &c.? The answer was by facts which occured in other countries. In Germany, after the introduction of the tariff, there was such a rush of brain and muscle from all professions and trades into industrial enterprises that the wages of all other trades had to be raised periodically, as had also been raised periodically by Act of Parliament the remuneration of civil servants, schoolmasters, professors, municipal servants, &c. That process of levelling up was going on constantly.

In his pleading for Free Trade, Mr. Oppenheimer referred, as one of the causes of Germany's present greatness, to the Zoll Verein, which broke down the customs barrier within the German States. The speaker agreed that that was the beginning and that was all that we wanted. We also wished to have internal walls broken down and barriers round the whole of the British Empire just as in Germany and America. Again, Mr. Kingsbury had asked why he had selected the year 1880. He (Mr. Hirst) took it for granted that Mr. Kingsbury knew that Bismarck introduced Tariff Reform into Germany in 1878 and 1879. It took, of course, a number of years before the effects of this change made themselves felt, and for the purpose of taking a round figure he had selected 1880. He might as well have taken any year between 1878 and 1885, when we first felt, in a slight degree, German competition.

Mr. Kingsbury suggested that he (Mr. Hirst) was so narrow minded as to think only of the benefits to the manufacturer, and that there was no word about dearer clothing and food for the working men. If food and clothing should be dearer, it could well be defrayed by the higher wages which every manufacturer would willingly pay to the working man, if there were security of market. He had no hesitancy in declaring and proving by a practical illustration that if our wages were to go up 33⅓ per cent., if we could make the larger quantities which we should require through the security of our home market, we should still be able to produce more cheaply than under present conditions. Our foreign competitor would make less, we should make more, our cost of production would be more equal, and we should be better armed for the fight on the neutral markets. Mr. Kingsbury had remarked that in no protected country could an engineer extend his horizon beyond the frontier. That did not seem to be the case in Belgium, America, Germany and Switzerland. Further, most developments, if not all, originated in protected countries. They were either common property, and in that case other protected countries would avail themselves of them, as well as a Free Trade country, or they were new inventions and were patentable.

Mr. Kingsbury made a point of 6s. 10d. per head of the production of the American population, and 6s. 2d. per head of the English population, but he had included in the American figure the large Western States of black population.

Mr. Kingsbury had referred to the condition of the population of Great Britain as satisfactory. There were many, even Free Traders, who would disagree with this view. The position of the working classes in this country was a source of anxiety, the state of unemployment, the emigration and the great destitution in the big towns of this country not being approached at present in any other civilised country. Apart from such vague statements, Mr. Kingsbury did make a few definite assertions he would like to group into a short survey of the telephone industry. Mr. Kingsbury had said that protected States were behind in the development of enterprises originating in other countries. There might be a doubt whether the telephone was first invented in the States or in England, but there was no doubt that the industry started about the same time in both countries, and whilst our early factories had been compelled to shut down, what happened in the protected States, in America, in Germany and in Sweden? Did not the history of this enterprise in this country prove that an industry which originated in one protected State had flourished in other protected States more than under Free Trade? Could Mr. Kingsbury conscientiously tell them that telephones in this country were cheaper than in Germany, Sweden or America? We knew they were not.

Mr. Kingsbury said that "to start a factory for the purpose of serving as a school was an expensive form of education." Was it not a fact that all important improvements in telephony had come from the protected countries just mentioned? Did not the history of this industry prove clearly the statements in the speaker's opening address that inventions followed in the wake of busy workshops? The factory might be an expensive school, but it was the only proper school for technical and industrial education. Mr. Kingsbury then suggested that it was an advantage to have the market developed in a country before starting a factory. Well, we had the market for telephones for many years, but factories were not forthcoming. It was true that there were now several factories in this country, but, in Mr. Hirst's opinion, they had not come to strengthen Mr. Kingsbury's argument, but for quite another reason. He (Mr. Hirst) maintained that these factories had been established because during the last three or four years Tariff Reform or Protection had been in the atmosphere. So many manufacturers in this and other countries were quite certain that we must have Tariff Reform and were making their preparations. As a natural sequence to our ability to produce, Mr. Kingsbury would agree that orders had been placed in this country from the colonies, distinctly requisitioning British made telephone exchange material, as also orders from neutral countries. Was not this a splendid reply to Mr. Kingsbury's statement that if the home market went up the export might go down. He, the speaker, had always found that one influenced the other, and they went hand in hand if the production was sufficient. Thus it was that Germany to-day exported nine millions worth of goods whilst this country only exported three and a half millions, and German imports were less than half a million, while the imports into this country were one and three-quarter millions. If American exports had not increased to the same extent it was only owing to the fact of the protection of that country and to the absorption by their own market of everything they could produce.

Mr. Kingsbury compared dumping with underselling by the home manufacturer. This betrayed absolute want of understanding of the principles of dumping. The home manufacturers produced under equal conditions. If he sold below the cost price it could only have one end. The buyer for a time benefited, but it must ruin the producer. If the foreign importer imported into England below the English cost price, it was a different story. It was quite possible that such a price might still leave the foreign importer profit. If an industry were killed by dumping, then the benefit to the buyer in a Free Trade country would be gone; he would have to buy on the same terms as the buyer in a protected country, and, as recent experiences had shown us, he might even have to pay more.

Summarising, the effect of Protection would be:—

1. It would give us greater security in our home markets and enable us to produce in larger quantities.
2. By thus producing in larger quantites we should be able to produce more cheaply.
3. Cheaper production would enable us to make better preferential arrangements with our colonies and thus create more bonds of common interest between the different parts of the Empire.
4. By the imposition of duties we should have greater bargaining powers with foreign countries and in foreign markets.
5. We should train our working population to be skilled artisans to enable them to earn higher wages and add to their comforts in life.
6. We should become more strong and self-reliant for defensive purposes.
7. We should attract to the aid of the manufacturer the capital of the country for the life-blood of the industry.

Surely whilst the foreign manufacturer had all these benefits, supported by the whole machineries of their particular Governments, the British manufacturer in his compulsory self-reliance was at a great disadvantage.

The CHAIRMAN (Mr. H. W. Butler) said that the success of the meeting had been so great that their energetic secretary had decided to organise at an early date next winter further discussions on possibly that or similar subjects which were of equal interest to the electrical manufacturing industry.

ELECTRICITY IN AGRICULTURE.*

At the meeting of the German Agricultural Council, a good deal of information as to the results of various experimenters in the application of electricity to agriculture was made public. Dr. Höstermann reported on the work he had done at Dahlem, near Berlin, where apparatus manufactured by the Allgemeine Elektrizitäts Gesellschaft was used. Prof. Gerlach took part in the discussion, and described the experimental work he had carried out in conjunction with Siemens & Halske on the experimental farm at Mocheln, near Bromberg.

Dr. Höstermann's method consisted in treating vegetables by electrical radiation in four different ways. The vegetables included

* Abstract of a report in the "Elektrotechnische Zeitschrift," March 24, 1910. The full text of Dr. Höstermann's report appeared in the "Archiv des deutschen Landwirtschaftsrates," published by Paul Parey, Berlin, S.W. and Prof. Gerlach's experiments are described in the "Illustrierte Landwistschafttiche, Zeitung," Feb. 19, 1910.

Digitized by Google

spinach, lettuce, radishes, carrots and strawberries, each plot being as nearly similar as possible to the others of its kind, the only difference therefore being in the matter of electrical treatment. The radiation was effected by means of telephone wires, about 2 yds. above the ground level, and arranged at distances of 4 yds. apart. The different methods of treatment were as follows. (1) Certain plots were exposed to the normal atmospheric influences, and beyond this there was no special treatment. The yield in this case was taken as being 100 per cent., for purposes of comparison. (2) The plants of the second group were exposed to an artificial radiation by means of static electricity. The yield in this case varied from 115 to 140 per cent. (3) The plants of the third group were exposed to high tension oscillating direct current, which was furnished by dynamos and transformers. With a high voltage and lengthy treatment, the yield varied from 90 to 105 per cent.; with a milder form of treatment, the yield varied from 100 to 125 per cent; (4) The last group contained plants which were shielded from such electrical radiation as might be present in the atmosphere by covering them with earthed wire cages. The yield in this case was only 86·5 per cent.

These experiments show clearly that under certain conditions the growth of plants may be favourably influenced; but that everything is likely to depend on the type of treatment. It is curious that electric current, relatively speaking of considerable amount and high tension, and employed over very extended periods of time, appears actually to have an unfavourable influence. A better result was obtained with a milder form of treatment. It is needless therefore to aim at very high voltages and heavy currents; it is better merely to imitate ordinary atmospheric effects.

Group (2) appears to have given the best results. Here electricity was conveyed from the atmosphere by anchoring a captive balloon or several kites, at heights of 800 ft., to a steel wire rope. Assuming a variation of 100 volts per yard, we should have in this case a pressure of 25,000 volts, or thereabouts at our disposal. Whether such a pressure was actually reached, it is not possible to say, as there was no means of reading on the instruments beyond 5,000 volts. There are always periodic variations in the fall of potential in the atmosphere; it varies from hour to hour, and day to day. Moreover the time of year affects the matter: the falls are greater in winter than in summer, and are consequently greater with a low temperature than with a high one. The maximum occurs between December and February. In the course of a day, there is a minimum at the warmest time in the afternoon, and another less pronounced minimum during the night. The maxima occur shortly after sunrise, and about the time of sunset. There is a considerable rise in the fall of potential during fog, snow, hail or rain, and especially during thunder-showers. Dr. Höstermann thinks that the dampness of the atmosphere is as important as the dampness of the soil. The damper the air, the better the result is likely to be with electrical treatment; electrical radiation is likely to injure the plants in a dry atmosphere. It is better, therefore, to conduct operations in the early morning or in the evening, or on dull cloudy days. It is quite possible that the damp climate of England gives better results than the drier air of the continent.

As the result of his experiments, Dr. Höstermann gives the following rules. The radiations should never be carried out in hot sunshiny weather; at any rate, not in the middle of the day in the heat of summer, unless it is possible at the same time to keep the crop well watered. It is better to limit the work to the early morning, and late afternoon. In summer, soon after sunrise (the action of light is necessary for a proper assimilation), say, from 5.30 a.m. to 7.30 a.m., and then from 7 p.m. to 9 p.m., shortly before twilight; in spring and autumn, from 7.30 a.m. to 9.30 a.m., and in the evening for an hour or so before twilight; in winter, from 9.30 a.m. to 11.30 a.m. If the atmosphere is too dry, this may largely prevent the proper radiation. If higher voltages are used, other decomposition products may be produced from the atmosphere, which are not beneficial to plant-life, and may even be harmful. The radiation is unnecessary in rainy weather, seeing that any kind of downpour always brings with it decided electrical charges. The most favourable condition is a misty day. In England, with its damp, misty, and somewhat sunless climate, due to its insular position, it is not possible to notice any harm arising from too long or too heavy radiation. In a wet year, it is not improbable that an increase in the length of time during which the radiation is continued, might compensate for a deficiency in the amount of energy, radiated in the form of light from the sun. The influence of the wind must not be neglected on such experimental patches as may be under examination. The patches which are supposed to be merely exposed to the ordinary atmospheric influences, must be situated at a sufficient distance from those which are subjected to the radiation treatment. This distance depends partly on the height of the radiating wires, which should be at a distance of 20 to 50 yds. from any patch not supposed to be under their influence; and regard must also be had to the direction of the usually prevailing winds.

Prof. Gerlach and Dr. Erlwein also give the following results of the work which they have carried out at Mocheln. The ground was sown with oats, and 18 plots, each of 1,000 sq. yds., were taken. Twelve of these plots were exposed to electric radiation, while the remaining six, which were at a distance of 100 yds., were cultivated without any special treatment, and served as a standard of comparison. The radiation was either (1) through high-tension single-phase current, or (2) through high-tension static electricity, distributed through a positively charged wire-network, or through a negatively charged one. The high-tension alternate current was produced through a direct-current motor coupled to an alternator and a 20,000 volt transformer; the static electricity was generated by influence machines, driven by motors. The tension at the terminals of the influence machine was about 80,000 volts. The wire network was at a distance of 6 yds. from the ground. The space that was submitted to alternate current radiation was 6,135 sq. yds. in extent; that exposed to static electricity consisted of two plots, each 3,068 sq. yds. in area. One pole of the high-tensions generators was earthed, the alternate current voltage being about 20,000, and of the static discharge about 30,000. The energy in the alternate current radiation was 770 volt-amperes, whereas each static machine absorbed 30 watts. The radiation was continued for 45 days of 24 hours each. The total cost of the radiation amounted to £23 per acre in the case of alternate current, and £17 per acre with static electricity. These costs would be very much lower if it were possible to take current from a power station, which had high tension conductors at 60,000 volts. Supposing, for instance, that it were possible to connect up to a central station, having a voltage of 5,000, a special transformer being used to generate about 100,000 volts. Then if energy were charged at the rate of 1d. per unit, the cost per acre for the alternate current treatment, extended over 45 days of 24 hours, would be about £2. 18s.; at ½d. per unit, the cost would be about £2. 7s.

Prof. Gerlach reports that as the result of this treatment, there was no noticeable difference during the growth nor in the yield of the plots so treated. The experiments were, however, continued with oats, the height of the network being lowered to 1½ yds. Further experiments were made during the summer of 1909 with direct current of low voltage. In this case, there were 7 plots, each of about 200 sq. yds.; three of these were subjected to the treatment, while the remaining four were untreated. At the sides of the plots, which were 10 yds. broad, strips of sheet iron, 20 yds. long, and 1 ft. broad, were buried in the ground, and connected to the rails of the local tramlines. The pressure amounted to 6 volts, and the current varied from 0·2 to 0·4 amperes. Some of the plots contained barley, and others were planted with potatoes. It was impossible to discover that this treatment produced any effect.

These reports therefore seem to show that Gerlach's treatment produced negative results, while Höstermann, on the other hand, found that under given conditions it was possible to produce a favourable result. The experiments in Dahlem are therefore being continued at the present moment. The work is in the hands of the Government authorities, who receive assistance from the Allgemeine Elektrizitäts Gesellschaft, from the Gesellschaft für Drahtlose Telegraphie, and from the firm of Alexander Siewert.

Temperature Measurements of Concrete by Electrical Methods—The "Electrical Review and Western Electrician" gives an account of measurements that are being made in the Panama Canal Zone of the heat generated by the hardening of Portland cement. For this purpose, six resistance thermometers will be embedded in the walls of the locks at Gatun and readings will be taken of the temperature at various stages of the hardening of the concrete. The following account of the arrangement is taken from the "Canal Zone." "From the time concrete begins to crystallise until it reaches its final set the increase in temperature is rapid. From the setting point the increase is slow, but usually continues during the whole of the hardening process, which is indefinitely long, probably lasting for several years. It is to gather data with regard to this hardening, and the heat produced by the chemical changes that accompany it, that the thermometers will be embedded in the concrete. In the thermometer here used an iron cup is employed to contain the resistance, and the wires are lead covered. The results will be plotted and a complete record of the hardening and cooling of the cement thus obtained."

COMMUTATION PHENOMENA AND MAGNETIC OSCILLATIONS IN D.C. MACHINES.

We give below an account of the discussion that took place at the meeting of the Birmingham local section of the Institution of Electrical Engineers when Mr. G. W. Worrall, M.Sc., read his Paper on the above subject. An abstract of this Paper appeared in our issues of May 13th and 20th.

The CHAIRMAN (Mr. R. K. Morcom) complimented the author on his Paper and on the interesting lecture in which he had dealt with the subject; this lecture had been far more useful than the usual abstract. Commutation was an intricate subject; this was obvious to anyone who watched dynamos under test and saw the empirical way in which many representatives of electrical firms set to work to cure heating of brushes and sparking.

Dr. KLOSS noticed that in the oscillograms there was always a combination of two different kinds of oscillations; one due to the movement of the armature teeth in the magnetic field, the other due to the commutation of the current in the coils. He thought it would be an advantage to be able to get rid of the first of these oscillations, and this might be done as follows:—If a four-pole lap-wound machine were taken and run with only two brushes, then the oscillations induced in a search coil on one of the poles opposite the brushes would contain both sets of oscillations, while that induced in a coil on one of the other poles would contain oscillations due to the movement of the armature teeth only. By connecting these coils suitably it should be possible to annul and leave only the oscillations due to the commutation currents. He did not know whether such a method would be possible, but he suggested it for Mr. Worrall's consideration. There was another point in connection with the research. Mr. Worrall had used a brush whose width was equal to one segment plus insulation. Now, in practice the brushes used covered more than one segment, and he would like to ask whether the author could give any information as to what happened in that case. Mr. Worrall had in his theory of commutation assumed that the specific resistance per square centimetre of surface of the brush was constant, whereas actually this was not the case. Would Mr. Worrall's results be modified by this fact? He endorsed the author's remarks about the possibility of improving the performance of a machine by decreasing the contact area of the brushes and increasing the current density. He had known specifications which had stated that the current density in the brushes must not exceed a certain figure, and which left the designer of the machine with the alternatives of either supplying a poor machine, in accordance with the specification, or a good one in which the specification was departed from. He thought that in preparing their specifications consulting engineers should leave points like this to the discretion of the designer. He also drew attention to the importance of keeping down the temperature of the commutator both from the point of view of commutation as shown in the Paper, and also in order to prevent mechanical trouble due to expansion and contraction of the commutator bars, especially in the case of turbo-generators. This could be done by making the segments hollow and arranging for the passage of air through them, as was done in the Siemens ventilated high-speed commutator, which had given so great satisfaction.

Mr. T. F. WALL, referring to Fig. 1 of the Paper, said that large oscillations were obtained in coil 5, whereas in coil 8 there were practically none. He thought this probably meant that they had been damped out by the field winding, and that if the oscillograph had been connected across the terminals of the field coil similar results might have been obtained as were obtained from coil 5. Another suggestion he had to make was that the damping action of the field coils might possibly materially decrease the inductance of the short-circuited coils and thereby improve the commutation of the machine. He would like to point out that the pulsating flux due to commutation traversed the main axis of the coil, and thereby induced in the armature winding an E.M.F. due to rotation which was in phase with the flux and therefore with the current producing that flux. If, therefore, records were taken of the E.M.F. induced between the main brushes, the variations of the commutation current might be examined and compared with the records obtained by means of coil 5, which latter showed the rate of change of the commutation current. A great deal of discussion had recently occurred as to what really happened in a coil undergoing commutation. It seemed to him that taking a conductor approaching the commutation zone the lines of force were crowded together behind it and spread out in front. As it passed through the region of commutation this distribution was changed so that the conductor finally left with the flux crowded up in front and spread out behind. As the conductor moved along, the lines followed but did not cut it, so that the actual field in which the coil was moving might well be zero.

Dr. Ing. E. ARNOLD (Karlsruhe, Baden), in a written communication, thought the influence of magnetic oscillations on the commutation of direct-current machines was often underestimated. With reference to the first part of the Paper, in the writer's opinion, a commutating field was always necessary in order to compensate the self-induction. Commutation could not take place in a neutral zone, because the self-induction of the end connections could only be compensated by a field, to which a coil side was subject. The different fields did not coincide, and consequently they did not combine to form a resultant field. He agreed with the author's remarks about the effect of a brush, the resistance of which increased from the rear tip to the forward tip, but such an increase of resistance occurred also, automatically, with brushes of rectangular section. Experiments had shown that the current density in those parts of a brush that sparked was very small and the tension high, thus the contact resistance was very high. Because of very small, almost invisible, sparks at the forward tip the contact resistance per square millimetre of brush surface at this tip might increase to 50 times that at the rear tip, or even more. Bad contact, as a result of sparking, was the cause of this phenomenon. The specific resistance varied, automatically, between wide limits, preventing too large an increase of the short-circuit current. As long as the sparking was not excessive, the current density was always small. Sparking with a high current density was so violent that the commutator was damaged very rapidly and further service became impossible. For the above reasons an artificial disposition of the resistance over the contact surface (as in Fig. 8) would not be as successful as one would expect from theory, based on a constant value of the specific resistance. What the author called "the natural period of commutation," which must be smaller than the "available period," was not sufficiently well defined. The natural period depends upon the commutating E.M.F.s, and was consequently a quantity which could be varied with one and the same armature. According to theory * one condition for sparkless commutation was $\frac{s_T \cdot T}{a \cdot L} > 1$, where s_T specific resistance of the brush at the forward tip, T = duration of short-circuit of coil in seconds, a = total surface of brush, and L coefficient of apparent self-induction of coil. Let $T_u = \frac{a \cdot L}{S_T}$ be the duration of a natural period. The condition for sparkless commutation was then $T_a > T_u$, where T_a = the duration of the available period. For small values of T_a (high-speed machines) this condition could only be fulfilled by the introduction of a commutating E.M.F., which compensated part of the self-induction. Mr. Worrall's remarks about the construction of brush-holders and the cooling of brushes were very interesting and important. His experience materially facilitated the design of a good brush-holder. Results of elaborate experiments on commutation had been published by E. Arnold and F. Jordan in "Arbeiten aus dem Elektrotechnischen-Institut der Technischen Hochschule zu Karlsruhe, 1908-1909." This dealt with current density, variation of the specific resistance of the brushes, duration of commutation, losses under the brushes, reaction of the short-circuit current on the main field, and with field pulsation. The inconstancy of the magnetic field was partly due to pulsations, *i.e.*, alterations in the intensity of the field, and partly to oscillations, *i.e.*, to a movement of the field alternately with and against the direction of rotation of the armature. The oscillations were caused by the armature teeth passing the poles, and were described as "flash" and "drag" in a previous Paper by Mr. Worrall. Equipotential connections damped the pulsations of the field effectively, but not the oscillations, because the plane of the induced equipotential loop coincided with the direction of the field. Solid pole shoes, or better, short-circuited windings in the pole shoes (amortisseurs), damped the oscillations. Such oscillations particularly affected the commutation of machines with a large flux per pole. For such machines solid pole shoes and a long air-gap were thus to be preferred to laminated pole shoes and a short air-gap. It appeared that the kind of magnetic oscillations and pulsations and also their magnitude depended upon individual features of the machines. They might be very different for two machines of the same design and with the same dimensions. Sometimes a kind of resonance took place, *i.e.*, the oscillations from various causes strengthened one another. In other cases they might oppose one another. To show the detrimental effect of these pulsations and oscillations of the field, he mentioned two cases which had come to his notice. In both cases the addition of equipotential connections cured the sparking trouble.

Prof. E. W. MARCHANT (communicated) remarked that Mr. Worrall was to be congratulated upon having devised a brush-holder which would give consistent results for the surface resistance of brushes. With reference to the contact maker described, Mr. Duddell and the writer did a great deal of work with contact makers about 12 years ago and found that the most satisfactory form was one in which two pieces of watch spring clamped to a piece of ebonite supported on the end of the frame of the machine were short-circuited by a copper plate attached to the rotor. The springs projected radially inwards and were about an inch long, soldered into brass rods. This contact-maker was exceedingly simple, and gave excellent results. The emphasis which Mr. Worrall laid on the difference between commutation at a positive and at a negative brush was of great importance. The results given for the Le Carbone Z brush were considerably modified by current density and by the type of brush. In some tests made in the Electrical Engineering Laboratories of the University of Liverpool by Messrs. Cottle and Rutherford, it was found that the ratio of drop on positive brush to drop on negative brush varied within wide limits for different current densities, being greater than 1, equal to 1 or less than 1, according to the current used. These results would, he hoped, be published shortly, so that he would not refer to them at greater length. The greater sensitiveness of negative brushes to variation in temperature, current density, &c., had been frequently noticed, but Mr. Worrall's method of getting rid of chattering was most ingenious. It seemed almost incredible that changes in temperature of the brush could be sufficiently rapid to cause chattering. He asked Mr. Worrall whether he was quite certain that the result obtained was not due to a mechanical effect caused by the addition of the copper and copper foil to the brush. The copper foil was insulated from the carbon by mica, and this material, of course, besides being a bad conductor of electricity was also a bad conductor of heat.

Prof. D. ROBERTSON (communicated) thought Mr. Worrall had made the theory of commutation appear needlessly obscure. The following was the method of putting it, which the writer had adopted for years. During the time that a coil was short-circuited by the brush, she current in it had to die away and a new one to grow in the opposite way. If it had exactly the proper value at the instant the short circuit ceased, the current in the segment leaving the brush would be zero and there would be no spark on breaking contact. It if had not reached that value, or if it had grown too large, there would be a current in the old segment, which, since the current in the coil refused to change instantly, continued to flow in a spark after the brush had left the segment. This was the spark that did most of the damage, and was the only spark possible if the brushes were making perfect contact. The condition for the avoidance of this spark was the simple one that there should be no current in the old segment at the instant it left the brush, and it did not greatly matter how the current had changed during the short-circuit so long as this final condition was satisfied. Any other sparks at the brushes could only be caused by faulty contact between the brush and segments due to bad surfaces, or to mechanical vibration caused by unsuitable brush gear, or by the thermal effects referred to by the author. The sparking at the rear tip mentioned must be due to these causes. Sparking took place at the forward (breaking) tip whether the commutating E.M.F. was too small or too great. The inductance of the coil opposed the change of the current and was the prime cause of the trouble. The mutual inductance between adjacent coils simultaneously undergoing commutation was also a good second, particularly when they were in the same phase at the same instant. The resistance of the coil itself and of the lugs helped to kill the old current, but also hindered the growth of the new, and so did not produce much direct effect on the commutation of continuous current machines. It was, however, useful and even necessary in alternating-current machines, as it reduced the short-circuit current caused by the transformer E.M.F. In all cases it reduced the effectiveness of the brush contact resistances, by diminishing their ratio to the total, and to that extent it was harmful. Brush contact resistance promoted the change of current because it was gradually shifted from the new segment to the old one. If its effect were so large as to make all the others negligible, the current entering each segment would always be proportional to the area of contact on that segment (assuming uniform contact resistance), and the commutation would be a straight line or a series of straight lines, according to the width of the brushes. This distribution of the current, which might be termed the natural one, gave smaller contact losses than any other. Actually the inductance E.M.F.s were not negligible, and the current departed from this distribution and the losses were increased. To counteract the inductance E.M.F. a *motion* E.M.F. was induced in the short-circuited coil by giving the brushes a lead in the right way, by adding commutating poles, or by putting special coils between the segments and main winding (Sayers). Commutating poles were the most effective, because they could be excited in series with the armature and their effect made proportional to the work to be done. Many problems could be much simplified if we could get away from some of the conventions of our predecessors, such as the addition of fluxes instead of the excitations producing them. The author's explanation of the action of commutating poles was an example. The commutating pole reduced the reluctance in the path of the armature cross flux, and would therefore increase that flux if the commutating poles were not excited. But the excitation required to balance the armature reaction was not affected by that fact, and would be exactly the same whether the commutating pole were made of iron or of wood. The commutating pole coil must have sufficient additional excitation to magnetise it and the air-gap and teeth to the degree necessary to induce the required commutating E.M.F. and this additional excitation was, of course, very much smaller with an iron core. The "relative movement" idea (on p. 13) was a rather dubious one, as the two induced E.M.F.s were of quite different natures, one being due to change of position and the other to change of current. Also, the mathematical theory and the brush shape deduced from it were not of much real value, for the conditions assumed were not those usually found in practice, and several important factors had been left out of account altogether. It was seldom that the brushes were as narrow as one segment width; and the mutual inductance of the neighbouring coils being commutated at the same time, even when the phase of commutation was not the same for both, was only a little less important than the self-inductance of the coil itself; and the resistance of the coil and lugs was not usually negligible. The author's "natural period" was a rather indefinite sort of thing. Even the "time constant" of the circuit (inductance÷resistance) had hardly a definite meaning here owing to the change both of the inductance and of the resistance of the short-circuit as commutation proceeded. The oscillograms were most interesting, but it was doubtful, however, whether they gave much information as to the process of commutation itself, beyond indicating the maximum rate of change of current; and even that was marred somewhat by tooth ripples. The usual way of applying the oscillograph to show the armature current, by splitting a coil and adding the oscillograph shunt through slip rings, was of little use, as the behaviour of the current must then be very different from that under normal conditions. In 1903 the writer devised a method of making the armature coil itself act as the shunt. The intended research, which had been delayed by the unfortunate fire at the Merchant Venturer's College, was now only in its preliminary stages. The principle used was exactly the same as had since been applied by Campbell to the design of non-inductive shunts. The method had been used with the tracing desk outfit for class demonstrations during the past three sessions, with most instructive results.

Prof. SILVANUS P. THOMPSON (communicated) considered the Paper one of the most important contributions that had been made for some years to our knowledge of commutation. Dealing first with a practical point, he praised the particular work on the irregularities of commutation which had been traced to the surface irregularities of the commutator and the vibration of the brushes, leading to the invention of a new type of brush and brush-holder. This would probably find a much wider application than in a mere experimental machine. Also the advice to plough out the lines of the mica insulation as they appeared at the surface of the commutator was wholly good. The writer had for many years found this treatment to improve the commutation in doubtful cases. At first it seemed a pity that Mr. Worrall's chief work had been carried out on a machine with an odd number of commutator segments, so that commutation did not occur simultaneously at the positive and negative brushes, the machine thus being not representative of the majority of continuous-current generators. But really this feature had been of advantage, as it separated the effects due to commutation at the positive brush from those at the negative brush. This part of the research was very instructive. The results emphasised the analogy existing between the processes going on in the contact resistances beneath a carbon brush and those going on in an arc lamp. In both cases there was a resistance which decreased with the current density, and in both cases the resistance was greater for currents leaving carbon than for currents entering carbon. The passages relating to the shaping of the carbon brush to give greater resistance at the forward tip were both instructive and convincing. They justified the old practice of using carbon tips to copper brushes, or the use of combined sets of brushes, in which one carbon brush was set in advance of the row of copper brushes. Equally important was the suggestion to furnish tips of all carbon brushes with cooling appliances of metal.

Mr. W. ARMISTEAD thought the theoretical considerations of commutation were quite burdensome, and it was only by attacking the subject practically that it was possible to come to any results likely to be of use to the manufacturer. The machine on which the author carried out his experiments was very large for the output. The author observed that there might be an actual reduction of temperature when the area in contact between the brush and the commutator was reduced. The experience of the writer's firm bore this out. Though so far as sparking was concerned they had not found that dividing up the brush by means of a slot or slots parallel to the shaft had been of any use. Large brushes appeared to be almost useless, no doubt largely owing to the bad conductivity of the carbon and the impossibility of radiating the heat. The contact between two surfaces such as the brush and the commutator could not be made at more than three points for each brush, no matter what size. He asked if the author knew Mr. R. V. Marshall's patent brush and holder. Bearing these points in view, this designed brush-holder was only ¼in. long along the axis of the commutator. They had tried this arrangement in practice and found that a large current could be collected per brush with the smaller brushes without an increased rise in temperature either of the commutator or of the brushes. This small brush would collect practically the same amount of current as one four times the dimensions. Unfortunately, practical difficulties came in the way of its universal adoption. The author spoke of the increased inductance in machines fitted with commutating poles; this actually seemed to be very much exaggerated. To begin with, the commutating poles were for the most part solid, and the very high frequency of the fluctuating currents in their vicinity precluded the possibility of any serious conduction of lines of force through this path. The writer had not been able to test the matter experimentally as the author had done, but had found that facing poles with sheet copper, and surrounding them with a stout band of the same material did not make the slightest difference so far as sparking was concerned. Of course, if the commutating poles were not excited properly there was bound to be a large amount of magnetic leakage when the armature was generating or receiving current, owing to the displacement of the neutral magnetic zone on the armature relatively to the yoke. He asked if the author could say that the contact resistance between the carbon and the copper of the commutator was reduced by an increase of temperature.

Mr. C. C. HAWKINS (communicated) said the question of whether the self-induced E.M.F. in the case of satisfactory commutation existed and was compensated for, or was rendered non-existent, resolved itself finally into the question of what was the actual physical field in which the short-circuited coil moved. The author's analysis, resting upon the component fields and planes normal to each other, did not at first sight seem to give clear guidance, owing to the great complexity of the actual practical case of the slotted armature. It appeared that a resultant commutating field must always be present at least in such amount and density as to compensate for the inductance, self and mutual, of the end connections; for the flux linked with the latter followed a path entirely different from that of flux entering or leaving the surface of the core. The remainder of the inductance of the short-circuited coils might be resolved into a certain amount due to lines crossing the air-gap and a certain amount due to the bending of the final field within the slot and about its neighbourhood. The former part was cancelled by opposing lines, so that it became non-existent in the resultant field. The latter part would call for some commutating flux sufficient to counterbalance the rate of change of bending of the actual lines so far as they cut the armature coils, the reason being that the M.M.F. of the commutating poles would never by itself straighten the distorted lines near the coils within the slots, so that the third part of the inductance could not be strictly annulled but must be compensated for. Although the distinction between the material and the available period of commutation was up to a certain point useful and valid, yet it contained an

Digitized by Google

element of indefiniteness which rather limited its usefulness. What was a sufficiently close approximation to the final value to warrant us in regarding the time in which it was reached as the natural period? Even if successful in obtaining a natural period appreciably less than the available, then the difficulty arose of keeping the current at the required value during the remainder of the available period. The above criticisms which suggested themselves on first reading Mr. Worrall's Paper might, however, yield to a further study of it. The shape of brush, too, recommended by the author might be compared with the serrated edges which Mr. Carter (in the "Electrical World," March 31, 1910) recommended from an analogous point of view, viz., as valuable in unfavourable cases for keeping the current density at the last moment finite.

Mr. F. J. Moffett (communicated) mentioned that a case of the difference in behaviour of the positive and negative brushes recently came under his notice. The machine was designed for an output of 1,000 amperes at 80 volts and 700 revs. per min., and was provided with commutating poles. The brushes used consisted of a mixture of copper dust and carbon (Morganite Link 2/538), the current density being 85 amperes per square inch. When running at full load the commutation at the positive brushes was very good, but trouble was experienced at the negative brushes. The wearing surface of the negative brushes not only showed the brown bands mentioned by the author, but the copper was removed leaving the carbon alone. With an overload of 20 per cent., or 1,200 amperes on the machine, the commutation at the positive brushes was still fairly good, but at the negative the sparking became so vigorous as to make it impossible to continue the run. The removal of the copper from the negative brushes was even more marked at the overload than at normal full load, and the brushes became extremely hot. In order to remedy this trouble it was decided to substitute soft carbon (Morganite Link 1/289) for the copper carbon negative brushes, although these were naturally of higher resistance. The effect of the change was remarkable; not only was the commutation at normal load almost perfect, but even at 1,200 amperes there was no serious fault to find, and the alteration was quite successful in permanently curing the trouble. From an examination of the copper-carbon brushes on the positive and negative poles respectively, there appeared to be some justification for the assumption that the copper was carried along by the current by a kind of electrolytic action, but it was possible that the temperature at the contact surface of the negative brush reached so high a value as to render the copper molten, in which state it was carried away by the commutator segments. In support of this explanation, in the space between the commutator segments there was a considerable amount of copper which did not appear to be derived from the commutator bars.

Mr. H. G. Stephens (communicated) expressed his appreciation of the Paper, and suggested that the experiments be carried further. For instance, the case when only one coil was short-circuited was the simplest possible case and was comparatively rare in practice. Regarding equation (1) on page 9 of the Paper, it appeared that this was incomplete even for the purely hypothetical case considered. If r represented the resistance of the one coil, he thought the equation should be $E = ir + L\frac{di}{dt} + i_2 r_2 - r_1 r_1$. If this were so, the shape of the ideal brush would apparently be altered. Further, straight line commutation was not always a desideratum, as in the case of high-speed machinery, *e.g.*, turbo-generators, accelerated commutation was sometimes found to give better results.

Mr. Worrall, in reply, stated that the method of cancelling the tooth oscillations suggested by Dr. Kloss would only be possible in the case of a machine in which the workmanship was perfect and the magnetic quality of the iron uniform. No oscillograms were taken of the field exciting current, but from previous experience with laminated pole shoes and limbs it was evident that the non-existence of magnetic oscillations in coil 8P was due mainly to the use of solid poles and limbs. If the oscillograph were connected across the brushes the main E.M.F. would be so large that all commutation ripples would be invisible on the record: this, however, could be easily overcome by the use of a constant opposing E.M.F. Even then, however, the result would be confused by the variations of E.M.F. due to the spacing of the winding. The theoretical aspect of the question would probably always form a safe battle ground, for so much depended upon the terms employed, upon the way in which the problem was attacked and most of all upon the assumptions made. The results theoretically deduced could, at the best, only be approximate, but, as stated in the Paper, they might "point the way" to something practical. Such had been the case in this research, and, although for the sake of simplicity much had been intentionally left out in the theory, the theoretical result in Fig. 7 suggested and explained the practical result in Fig. 8. The explanation at the commencement of Section 1 of the Paper was only given to reconcile in some measure apparently conflicting statements and did not form part of the theory which followed. The remarkable confirmation of the results by Mr. Moffett was of very great interest, and it was to be hoped that others in charge of running plant would experiment in the same direction. The The suggestion of Prof. Marchant regarding the vibration of the negative brush did not explain the fact that the brush when positive did not vibrate even without the cooling device. The researches of Prof. Arnold had greatly assisted the work, and Prof. Robertson's research would be looked forward to with interest. Prof. Thompson had given a sufficient answer to all criticisms regarding the type of machine and brush employed, and it only remained to add that were two more years available they could be usefully employed in extending the research on the lines suggested by several speakers.

VARIATION OF THE HALL EFFECT IN METALS WITH CHANGE OF TEMPERATURE.

In a recent issue of the "Physical Review," Mr. A. W. Smith describes experiments on the temperature coefficient of the Hall effect. The author finds that the effect in gold, zinc, platinum and silver decreases as the temperature is raised from −190° to about 22°C. In the case of aluminium there is an increase. The Hall E.M.F. in each of these metals at the temperature of liquid air has been found to be proportional to the magnetic field. In silicon it has been found to have sometimes the direction of the effect in iron and sometimes the direction of the effect in bismuth. The purer specimens gave the effect in the direction of that in iron. A reversal of the thermo-E.M.F. in silicon has been found to be associated with a reversal of the Hall effect, and the Hall E.M.F. in silicon is shown to be proportional to the magnetic field.

The relation between the Hall E.M.F. and the magnetic field has been examined in iron, nickel and cobalt for a number of temperatures between −190° and 1100° C. For a given magnetic field the Hall effect in these metals has been found to increase with rising temperature until the critical temperature of the metal in question has been reached. The rate of increase becomes the greater the nearer the critical temperature is approached.

In passing the critical temperature the effect sinks rapidly to a small fraction of its original value, and then in the case of iron and nickel, and probably in cobalt, decreases slowly with further rise of temperature. In the magnetic metals for any particular temperature the Hall E.M.F. is proportional to the magnetic field, until the maximum intensity of magnetisation in the plate has been reached. After this condition, which has been called saturation, has been reached, the curves showing the relation between the Hall E.M.F. and the magnetic fields are nearly parallel to the axis of magnetic fields.

With increasing temperature the fields necessary to produce saturation become less in nickel and iron. In cobalt, however, the fields for saturation become greater with rising temperature until 300° is reached; and with further rise of temperature the fields for saturation become less. In nickel, iron and cobalt at temperatures a few degrees above the critical temperature the Hall E.M.F. is proportional to the magnetic field over its range in these experiments.

It is also pointed out by the author that the explanation of Sir J. J. Thomson, that the reversal of the Hall effect in iron may be due to the fact that the field actually acting on the free electrons is not only the impressed external field but also the field due to the orbital motion of the electrons in the metal, is improbable, in view of the fact that the effect in iron does not reverse sign at temperatures above the critical temperature where it has lost nearly all of its magnetic properties.

BOOKS RECEIVED.

(Copies of the undermentioned works can be had from *The Electrician* office, post free, on receipt of published price, adding 3d. for books published under 2s., and 5 per cent. for books published nett. Add 10 per cent. for abroad or for foreign books.)

The Rates for Subscription to "THE ELECTRICIAN" are as under —

	Year.	Half-Year.	Quarter.	
United Kingdom .	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Canada	28s. 3d.	14s. 6d.	7s. 6d.	
Postal Union ...	30s. 0d.	16s. 0d.	8s. 0d.	

New volumes of "THE ELECTRICIAN" commence in April and October.

(This charge includes all Supplements.)

Vols. I. to LXIV. can now be supplied. Price on application.

"THE ELECTRICIAN" SERIES OF STANDARD ELECTRICAL BOOKS

can be obtained of all Booksellers at Home, in the Colonies, and Abroad.

THE "ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1882. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Dec. 31st in each year for the next following edition) 8s. 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s.; Europe, 2s.; U.S.A., 3s. 6d.; other countries, 2s. 6d. *Digest of Contents sent free on application.*

THE "G.T." GEOGRAPHICAL DIRECTORY OF THE U.K. (Electrical Section). Subscription 5s., post free.

"THE ELECTRICIAN" PRIMERS (81 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three separate Vols. now ready.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS. By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [abroad 13s.

VOL. I.—Price 12s. 6d. post free, aoroad 13s. VOL. II.—Price 12s. 6d. post free,

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A. Fleming. Vol. I., 12s. 6d. nett, Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett; or bound in strong cloth, 15c. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

A SMALLER SET of only 40 Forms, bound strong cloth. Price 7s. 6d. nett.

CENTENARY OF THE ELECTRIC CURRENT—1799-1899. By Prof. J. A. Fleming, F.R.S. Price 1s.; strong cloth 2s. 6d.

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d. nett.

RADIO-ACTIVITY: AN ELEMENTARY TREATISE, FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Geipel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S. Price 10s. 6d.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By G. M. Baines. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d.

"THE ELECTRICIAN" WIREMAN'S POCKET BOOK. Edited by F. C. Raphael. Price 5s. nett.

"THE ELECTRICIAN" HANDY WIRE TABLES FOR THE POCKET. By P. B. Down, Wh.Ex., A.M.I.Mech.E. Price 2s. 6d. nett.

THE RATING OF ELECTRIC LIGHTING, ELECTRIC TRAMWAY, AND SIMILAR UNDERTAKINGS. By W. G. Bond, M.I.E.E. Price 2s. 6d. nett.

DRUM ARMATURE WINDING AND COMMUTATORS. By F. M. Weymouth. 7s. 6d.

PRIMARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By W. R. Cooper. Price 10s. 6d. nett.

SECONDARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By E. J. Wade. Price 10s. 6d. nett.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. Price 1s. 6d.

THE LOCALISATION OF FAULTS IN ELECTRIC LIGHT CABLES. By F. C. Raphael. 7s. 6d.

THE STEAM-ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont, M.I.C.E., M.I.M.E., &c. Price 6s. nett.

THE ELECTRIC ARC. By Mrs. Ayrton, M.I.E.E. Price 12s. 6d.

TRAMWAY TRACTIVE EFFORT AND POWER DIAGRAM. By Arnold G. Hansard, B.A., A.M.I.E.E. Price 4s. 6d. nett; in Tube, 5s.

THE BRITISH POST OFFICE TELEPHONE SERVICE. Fully illustrated.. Price 3s. 6d. nett.

INTERNATIONAL TELEGRAPH CONVENTION AND SERVICE REGULATIONS. Price 6s. nett. (LISBON REVISION, 1908.)

BOILER FEED WATER. By F. W. Anderson. Price 6s. nett.

(PRELIMINARY) WIRELESS TELEGRAPH CONFERENCE (BERLIN, 1903), PROCEEDINGS AT. Price 8s. 6d. nett.

INTERNATIONAL WIRELESS TELEGRAPH CONVENTION AND SERVICE REGULATIONS (BERLIN, 1906). With complete report of Proceedings. Price 21s. nett.

THE CLASSIFICATION OF ALTERNATE-CURRENT MOTORS. By V. A. A. Fynn, M.I.E.E. Price 3s. nett.

ELECTRIC CRANES AND HOISTS. By H. H. Broughton. *In Preparation.*

PRACTICAL TELEPHONY. By W. Aitken, M.I.E.E. *In Preparation.*

ELECTRIC MAINS AND DISTRIBUTING SYSTEMS. By J. R. Dick, B.Sc., and F. Fernie, A.M.Inst.C.E. *In Preparation.*

THE PRACTICAL WIRELESS SLIDE RULE. By Dr. H. R. Belcher-Hickman. Price 2s. 6d. nett. *Nearly Ready.*

THE MECHANICAL DESIGN AND CONSTRUCTION OF GENERATORS. By R. Livingstone. *In Preparation.*

LIGHT, RADIATION AND ILLUMINATION. From the German of Paul Högner, by Justus Eck. *In Preparation.*

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The forty-ninth issue of the Supplement was published (Gratis) with the number of "THE ELECTRICIAN" for May 27

The "INDUSTRIAL SUPPLEMENT" is a comprehensive record of developments in Electrical Plant, Machinery, Apparatus, Accessories, Sundries and Materials, and of their proved suitability for various Industrial purposes.

The "INDUSTRIAL SUPPLEMENT" is holed for filing or hanging, and filing covers can be supplied for holding 6 or 12 issues.

SPECIAL NOTICE.

NOW READY.—Vol. LXIV. of "THE ELECTRICIAN" (1,085 pages) bound in strong cloth. Price 17s. 6d.; post free, 18s. 6d. Now ready. Cases for Binding. Price 2s.; post free, 2s. 3d.

A complete set of "THE ELECTRICIAN" can be supplied. A number of odd volumes and some odd old back numbers, to help in making up complete sets, are also available.

ELECTRICITY IN AGRICULTURE.

There has of late years been a development of activity in Germany in a direction which has been but little exploited in this country, and which seems likely to lead to the profitable employment of capital. This is in connection with the supply of power for agricultural purposes; and though it might seem at first sight that the scope for this form of work is rather limited, in so far as financial considerations are concerned, it is not at all certain that this is the case. At any rate, those in Germany who are responsible for the further development of their distribution networks are not of this opinion, and a large amount of capital is being sunk in enterprises of this kind, which often enough are subsidiary to others already in existence. The tramway systems connecting Hanover with its outlying villages may be cited as a case in point. These tramways, which have been gradually extended in a variety of directions, have now spread so far into the country districts that the original scheme has been entirely revolutionised, and current is being transmitted to outlying points at very considerable distances from Hanover on the three-phase system, where it is converted to such other form of energy as is most suitable to the needs of the particular case. It is here that the opportunity arises of undertaking the distribution of energy to the agricultural districts. A large demand has in this way grown up, and the amount of power that is being used for

Digitized by Google

driving agricultural and village machinery of different types has become very considerable. This is not an isolated instance. These stations are becoming quite a common feature, and to the demands so created the large manufacturers are able to trace a notable portion of their output. It seems likely that high-tension alternating current, preferably of the polyphase type, is an almost necessary feature in the design of such undertakings, and there must be many places in this country where polyphase mains are suitably placed for such work, which might with careful handling be made to add to the output of the central station of the district. The German banks apparently think well of the outlook for this kind of enterprise, and there is no reason why a little experience should not be able to assure us that this spirit of hopefulness is indeed justified.

There is also another direction in which it seems likely that in the course of time electricity will be found to be a useful auxiliary to the farmer. Agriculture is the most ancient form of human activity, if we exclude the possibly pre-existing stage in which the human being was tempted to live by his wits as a hunter. It is not, therefore, surprising that in the course of centuries the industry should have become somewhat stereotyped. Experience in one form or another has always been the mainspring of the farmer's methods, and there are not lacking those who say that, in these days, rule-of-thumb methods must everywhere be considered antiquated. Of late years the stress of competition has led to the introduction of some new ideas, and chief among these is probably the welcome that has been extended to systems of artificial manuring. The fixation of atmospheric nitrogen has developed out of this, and in this field electricity seems likely to play a very successful part. But apart from this, or possibly as an extension of this, there is another direction in which the experimental enthusiast seems to be able to do useful work. A good deal has been done in the way of improving the yield in agricultural districts by the use of electrical methods. The abstract, which we publish in another column, of the reports presented by Dr. HÖSTERMANN and Prof. GERLACH shows that some of these plans are giving good results. As far as Prof. Gerlach's methods are concerned, it does not seem that he is able to show any results sufficiently satisfactory to lead further workers along the same lines. His plan seems to be to make use of the stray currents from tramway lines, in the hope that the electrolytic effects which are so disastrous to underground pipework may be beneficial to growing crops. On paper such an idea does not sound very hopeful, and in practice the results have been equally unpromising. On the other hand, Dr. HÖSTERMANN seems to have produced results which show that some of his methods are worth careful study. His most successful plan seems to have been to collect atmospheric charges by means of kites, somewhat on the lines of FRANKLIN'S classical experiments, and then to distribute these charges by means of wires stretched parallel to the ground at a small distance above the crops. He calculates that with a kite flying at a height of 800 ft. he is able to get a pressure of 25,000 volts; and, reading between the lines, he seems, as we imagine, to think that the effect is produced by some sort of automatic fixation of atmospheric nitrogen. This may quite possibly be the case, and if methods so simple as this avail to produce a desirable result it seems that the problem is scarcely an engineering one. He has made a variety of experiments in other directions, with different methods of producing the discharge, but none has given equally good results. Still even so, there is much that he quite willingly admits to be obscure. Whether or not some artificial method of obtaining the desired voltage will be an improvement on the kite system, a good deal of discretion and experience is needed before such a simple method even as this can be properly applied. A small amount of treatment goes a long way, and it is easily possible to overdo it. Indeed, he has himself drawn up a system under which he considers that the treatment can be most usefully applied. All sorts of organic reactions require or imply the presence of moisture in some form or another, either as a product of the reaction, or as a necessary preliminary before any reaction takes place. It is on this fact that he lays most stress, and he points out that the electrical treatment is useless, if not positively harmful, when applied in such a way that there is not sufficient moisture present in the atmosphere or in the soil. Still, it is quite possible that this moisture may not be required as an active agent in the stimulation of the growing crop, but as some sort of intermediary in the shape of a carrier. However, in whatsoever manner it acts, it is quite certain that without it little effect is produced.

From the point of view of the engineer, much of this is devoid of interest, and if the whole thing is merely likely to stimulate the manufacture of kites it does not seem likely to bring much grist to the mill of the electrical manufacturer. Still, all phases of electrical activity are of interest, and it is well known that there are many in this country who are already at work on the subject. It may be that other and more hopeful methods will be discovered as the outcome of human ingenuity, but, at any rate, it does not seem to be difficult to determine the directions in which time and money can easily be wasted. In any case, the amount of power which is needed for this kind of work seems to be very small, and we do not think that any station need hope to increase its output by delusions on that account.

SOME EXPERIMENTS WITH THE NEW TELEFUNKEN SYSTEM.*

BY GRAF ARCO.

Summary.—After showing how a singing spark signal is analogous both to a clear musical tone and a regular electrical discharge, the author goes on to describe a number of experiments which he has made with an 8 kw. apparatus working on the new system. He next gives figures for the efficiency of a somewhat smaller station working on the same system, and lastly shows how, by means of a special apparatus, the messages from two sending stations can simultaneously be picked up in one receiver.

I am taking it that the phenomena occurring in Wien's quenched spark-gap are sufficiently well known after my lecture at Cologne,† and I will, therefore, confine myself on this occasion to the peculiarities of sound generation and their use at a receiving station. These are the more important, for

* A lecture delivered before the Verband Deutscher Elektrotechniker, on the occasion of the awarding of the Siemens-Stefan Medal to Prof. Dr. E. Warburg, of Charlottenburg.

† THE ELECTRICIAN, Vol. LXIII., p. 370.

Digitized by Google

a number of improvements in the Telefunken System have been based upon them. In order to make the signals, such as would be received in the usual detector employed in connection with a telephone receiver, audible to a large audience, I have arranged the following small apparatus, which is shown in Fig. 1. This consists of a shaft driven by a small electric motor whose speed can be altered by means of a resistance, giving a variation from 3 to 1. On the shaft are fixed three wheels, one behind the other, which in the present case are taken from an ordinary cheap clock.

For the generation of signals similar to sound tones a visiting card or thin small wood plate is held against the teeth. At a

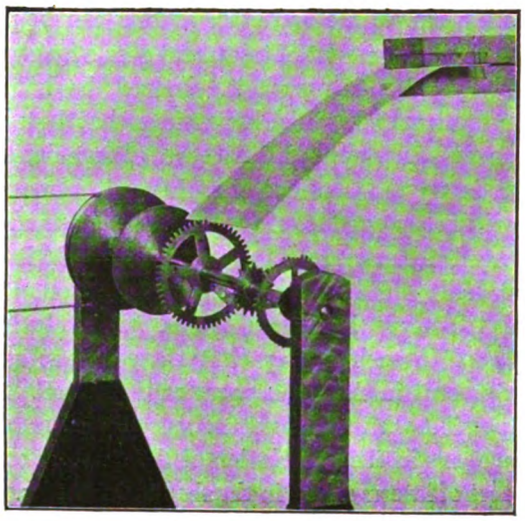

Fig. 1.

speed of two revolutions a second a wheel fitted with 20 teeth causes a sound similar to that obtained with a spark frequency of 40 per second. By altering the distance of the card from the wheel the Morse alphabet can be tapped out. The next wheel has about 90 teeth, about 20 per cent. of which are broken at irregular intervals. This wheel is used for generating sounds such as would be obtained by the irregular discharges obtained from atmospheric electrical phenomena. If spark signals and atmospheric disturbances are at work at the same time, and occur in different strengths, it is easily possible to discover in what relation the two intensities must stand for the Morse signals to be just readable. The third wheel has about 65 teeth regularly spaced round its periphery. This gives at about a speed of 16 revs. per second a clear sound of 1,000 frequency. This represents a singing spark station of normal pattern. It can thus be shown that signals with this sound can be recognised, even when the disturbances are more than 10 times as loud as the sound itself.

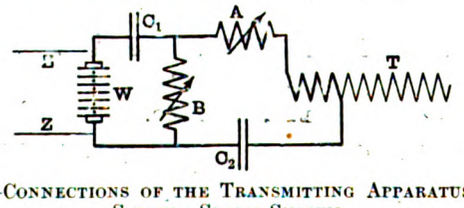

Fig. 2.—Connections of the Transmitting Apparatus in the Singing Spark System.

A similar sound was generated throughout the whole auditorium by means of an 8 kw. sender, working on the sending spark system. This apparatus is of a new pattern, the connections of which are shown in Fig. 2. The high-tension winding of the transformer charges the series quenched spark-gap which is connected with a surface condenser and variometer. These make up the quickly quenched primary circuit. The artificial antenna is coupled up with this circuit through a variometer and surface capacity, and a discharge coil is also connected with the antenna through a galvanic and inductive coupling. The discharge coil works in the well-known way, so that the capacity of the inductor is used as a counterweight instead of the earth. As soon as a voltage amplitude with about 20 cm. spark length is obtained at the free end of the coil, acoustic oscillations, corresponding to the different discharge conditions in the spark-gap, are transmitted from the point and are audible throughout the whole auditorium. When the sparks follow each other regularly a clear musical tone is obtained, while when the series is irregular there is simply a noise. The sound can, in the space of a second, be altered over as much as 22 octaves.

A further arrangement was connected up with this apparatus which made it possible at the same time absolutely to regulate the frequency, and thus to show that the clear sound only occurred when the sparks were regular, and a noise when they

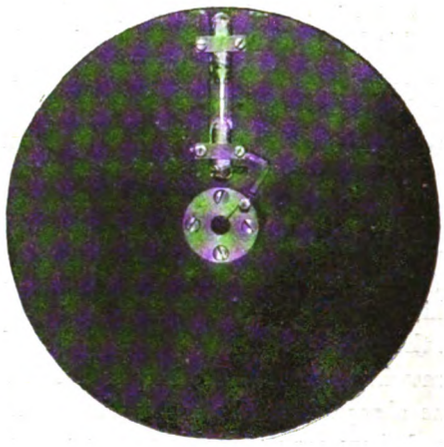

Fig. 3.—Rotating Geissler Tube.

were irregular. This arrangement consisted of a Geissler tube which, as shown in Fig. 3, is connected to a disc revolving in a radial direction. The disc revolved at 50 revs. per second while a high-frequency alternating current was passed through the tube. When a regular spark discharge with a frequency of about 1,000 is obtained, that is a clear sound, the rotating tube appears, as shown in Fig. 4A, in the form of a clear 20 pointed star, there being at each revolution exactly 20 discharges. As the photographic exposure was about one-fifth of a second,

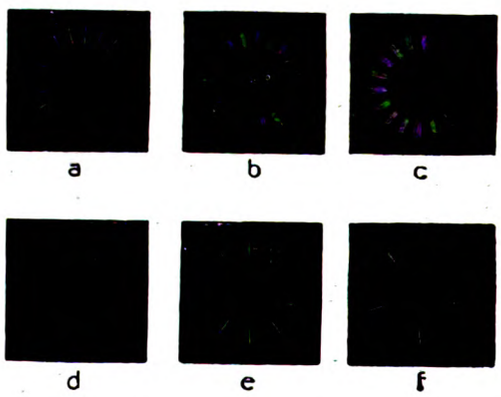

Fig 4.

there were in this period 200 discharges, that is each of the 20 points had glowed 10 times. In spite of this, on account of the great regularity, each ray is shown as a simple sharp line. The same holds good for all the following illustrations, with the exception of Fig. 4D. In Figs. 4A and 4F the frequency of the alternating current was constant, and equal to 500. When the alternator is more strongly excited a second discharge per alternation is set up, that is there are two partial discharges, as shown in Fig. 4B. With a still stronger excitation there are three partial discharges, as shown in Fig. 4C, the discharges per second in Fig. 4B being 200, and in Fig. 4C, 3,000 per second. In all these cases a musical tone was obtained. When the excita-

Digitized by Google

tion is considerably increased the discharges first become irregularly grouped, and instead of a musical sound a hissing is obtained, the discharge in this case being shown in Fig. 4E. If

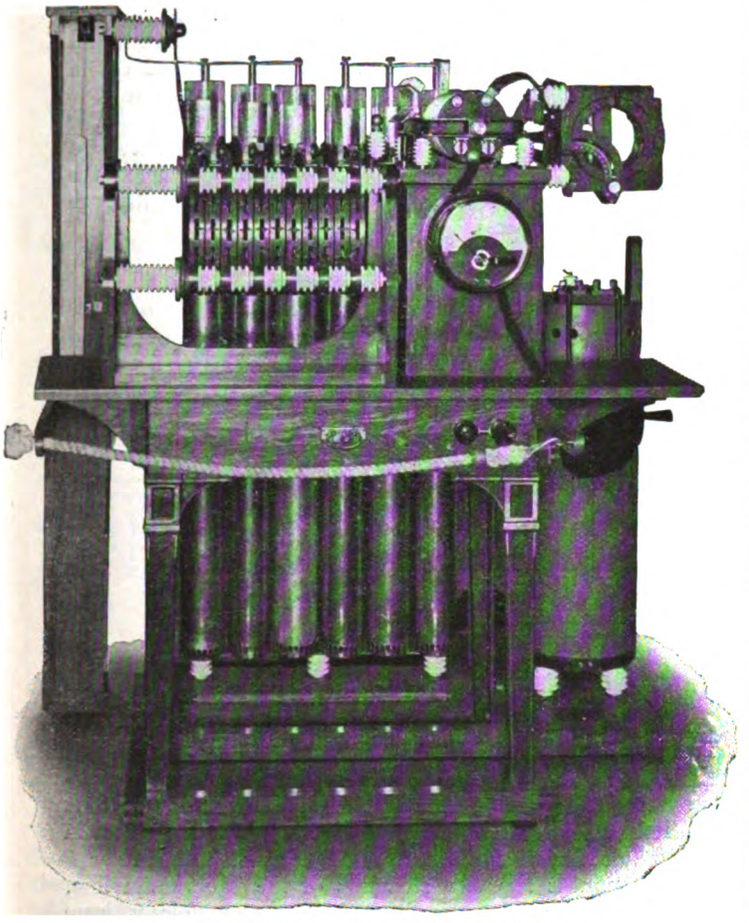

FIG. 5.—8 KW. SINGING SPARK STATION.

the generator is less excited, only one discharge is obtained every two, three or four alternations. Fig. 4E shows, for instance, a 10 pointed, Fig. 4F a five pointed, star, corresponding respectively to 500 and 250 discharges per second. In this way a clear tone can be obtained lying between two and three

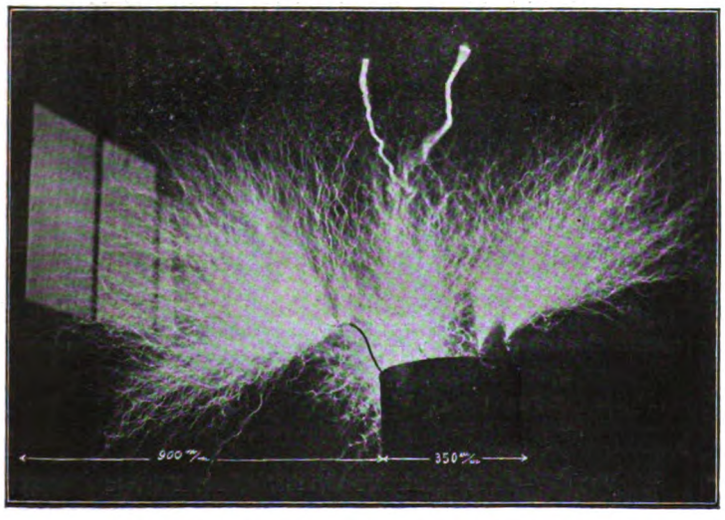

FIG. 6.—THE TRANSMITTING COIL IN OPERATION.

octaves under the fundamental, and the conditions of the obsolete spark telegraphy are very nearly reproduced, when an inductor resonance coupled loosely with a machine having a frequency of 100 alternations and giving out sparks up to frequencies of 25 and 50 is being used.

The standard 8 kw. station can be made to give any desired number of fundamentals, within the half octave above or below the normal, by a continual alteration of the speed of the alternator, and for each fundamental by means of faster discharges the first two overtones, and at the same time by slower discharges, the sounds of the three lower octaves can be obtained.

Dr. Fleming has made experiments on the regularity of spark discharges across spark-gaps subjected, and not subjected, to air draughts, as well as quenched spark-gaps, by using a rotating mirror, and he has photographed the results. As a result of his observations he came to the conclusion that a great regularity could not be obtained. He is only right in the cases when he is dealing with pressure discharges, as shown in Fig. 4D, otherwise with three discharges per alteration, and taking into account all the conditions, it is quite possible to obtain an absolutely regular and constant stream of discharges. This is shown by the photographs reproduced herewith, and by the experiments that I shall perform later.

I come now to the construction of the 8 kw. station, which is shown in Fig. 5. The transformer which steps up the machine pressure to about 20,000 volts and charges the exciting capacity is seen in the right background. A variable high-tension choking coil is placed in the secondary circuit, arranged for the correction of the resonance phenomena when it is desired to generate another tone by raising or lowering the speed. A variation of the sound over a whole octave continuously is possible, and the next three lower octaves can be obtained by altering the generating voltage at each speed.

The exciting capacity consists of Leyden jars which are arranged behind the table and an air-cooled series spark-gap, arranged in 12 parts placed higher up on the right. This is cooled by a ventilator not shown, and is connected to the variometer with a scale on the right. To one of the poles of this is connected a hot-wire ammeter and the earth, and on

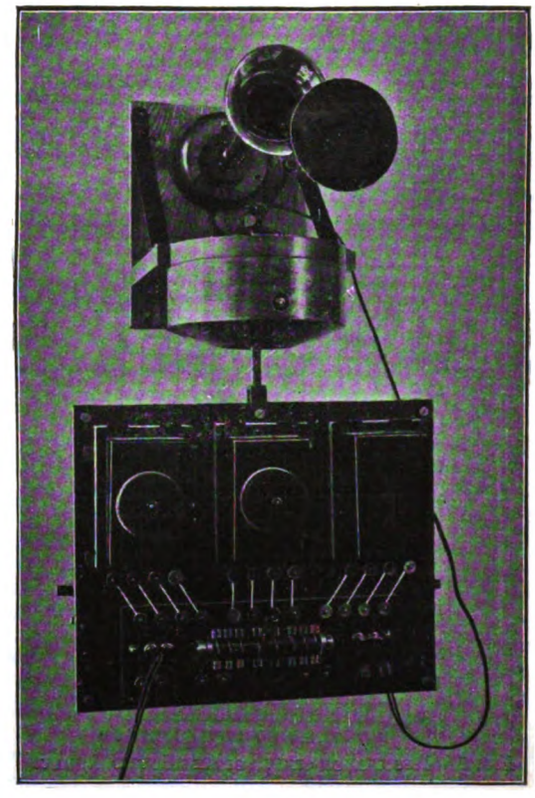

FIG. 7.—RESONANCE SOUND AMPLIFIER.

the other side through a series variometer, the antenna. The wave scale of this station rises continuously from 300 to 2,500 metres. Any desired wave-length can be obtained by altering the variometer while the coupling of the antenna remains absolutely constant at all wave-lengths. The 8 kw. delivered from the machine is divided up as follows :—In a

Digitized by Google

T-shaped ship antenna the current is 38 amperes, and the resistance of the antenna at 600 metre wave-length is 4 ohms. The energy delivered is therefore 5,800 watts, resulting in a total efficiency of 72·5 per cent. In my Cologne lecture I gave 60 per cent. as the efficiency of the new Telefunken System, and as this figure was questioned on different sides I propose now to give the several losses which occur in the 2 kw. type used at Cologne. These are set out in the following table :—

1.—Motor-generator.		
(*a*) Energy supplied to the motor		2,950 watts
Loss in the motor		450 „
		2,500 „
(*b*) Energy supplied to the 500 frequency generator.		2,500 „
Losses in generator		650 „
		1,850 „
2.—Transformer Circuit.		
Energy supplied to inductor		1,850 watts
Losses in inductor	180 watts	
„ in choking coil	60 „	
		240 „
		1,610 „
3.—High-Frequency Circuit.		
(*a*) Energy supplied to exciter circuit		1,610 watts
Losses in the Spark-gap	155	
„ „ „ Condenser	63	
„ „ „ Induction coil	42	
		260 „
(*b*) Energy supplied to antenna		1,350 „
Antenna current 13·5 amperes		
Antenna resistance wave-length of 1,200 m		8.5 ohms
Oscillation Energy in the antenna $= I^2W$		1,350 watts
(4) Efficiency of high-frequency transformation	$\frac{1350}{1610}$	= 84 per cent.
(5) Efficiency of low-frequency transformer	$\frac{1610}{1850}$	= 87 „
(6) Efficiency of A.C. Generator	$\frac{1850}{2500}$	= 74 „
(7) Efficiency of motor	$\frac{2500}{2950}$	= 86 „
(8) $\frac{\text{Antenna energy}}{\text{Motor energy}}$ Efficiency	$\frac{1350}{2950}$	= 46 „
(9) $\frac{\text{Antenna energy}}{\text{Generator energy}}$ Efficiency	$\frac{1350}{1850}$	= 73 „

In this connection I may call attention to a remark of Dr. Fleming's in an article published in THE ELECTRICIAN, of

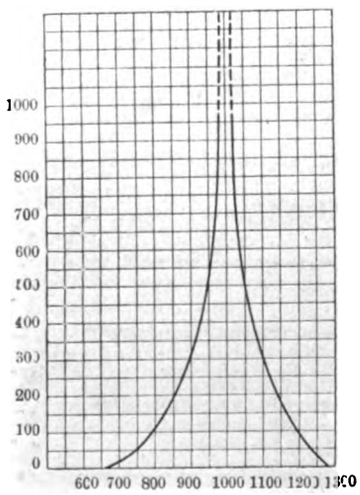

FIG. 8.—RESONANCE CURVE OF THE SOUND RELAY.

December 24, 1909, in which he gives a very low efficiency for a laboratory station, without wishing in any way to compare it with a station erected on technical lines. In our case antenna energy always means the sum of the actual amount transmitted from, and that lost in, the antenna, while Dr. Fleming understands by the efficiency the energy transmitted alone. It is not possible to determine the difference between these two values by measurement, as no exact method of doing so is at present known. Under certain conditions the efficiency of a good ship's antenna, when it is working with about 1·3 times the fundamental wave-length, should reach 50 per cent. The total efficiency between the transmitted oscillations and the load on the machine should be then about 40 per cent. It is quite possible to measure exactly the total energy in the antenna, and these values will in future be used by the Telefunken Co. in describing the sender energy. For these measurements it is not necessary to use any instrument beyond a hot-wire ammeter in the antenna, and to know the total antenna resistance at a given frequency, the latter value being obtained from the antenna resonance curve, or by measuring the current through it at different resistances.

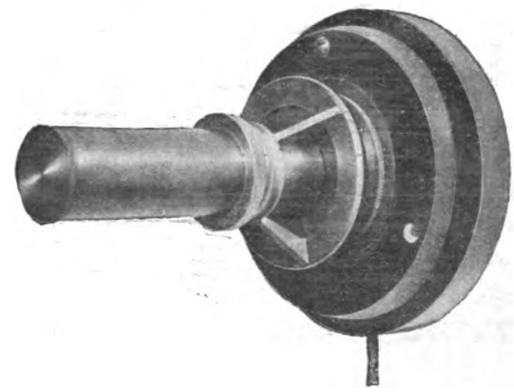

FIG. 9.—VARIABLE ACOUSTIC RESONATOR.

Turning once more to the experiments, the 8 kw. station is excited with about 5 kw. to 6 kw. in the primary, and the discharges are thus quite considerably increased. The thick bush discharge reaches a length of nearly 1 metre, as shown in Fig. 6, a quite impressive operation being thus obtained.

Several months ago two steamers of the Woermann line, which ply between Hamburg and the Cameron Colony, were fitted with stations of this type. Owing to the small mast height, the antenna was only 28 metres above the deck, and the masts being but a short distance apart, the length was only 67 metres, so that the conditions were unsuitable. But in spite of this it was possible to obtain communication at night between the two steamers over a distance of 3,200 kilometres in the region between the Canarian Islands and Cape Palmas. Communication was made more difficult by the presence of the

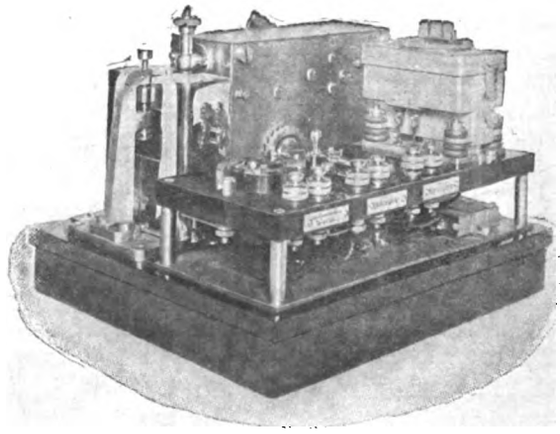

FIG. 10.—MORSE WRITER FOR SINGING SPARK WORK.

African Continent, whose length was about two-thirds of the distance covered. On January 23rd the two steamers were 3,700 kilometres apart at 10 o'clock in the evening, and were then able to get into good communication.

The use of a sound at the receiving station may now be shown by using the new resonance sound amplifier invented by the Company. Fig. 7 shows this apparatus adapted for ships use. On a board balancing in an elastically damped cardan suspen-

Digitized by Google

sion are mounted three sound resonance relays in series fitted with microphone contacts. The system is protected during the sending from the inductive working of the nearby sender by means of an automatic electromagnetic relay working in conjunction with the receiving apparatus.

The sound amplifier contains a well-known mechanical resonance system with small damping. Fig. 8 shows the mechanical resonance curve obtained from the amplifier. The curve shows the sensitiveness of the amplifier as a function of the increasing sound. In this way it is possible for different sounds from the senders to obtain a constant sound from the amplifier. It is evident from the curve that with a certain resonance the primary sound can itself be increased when it

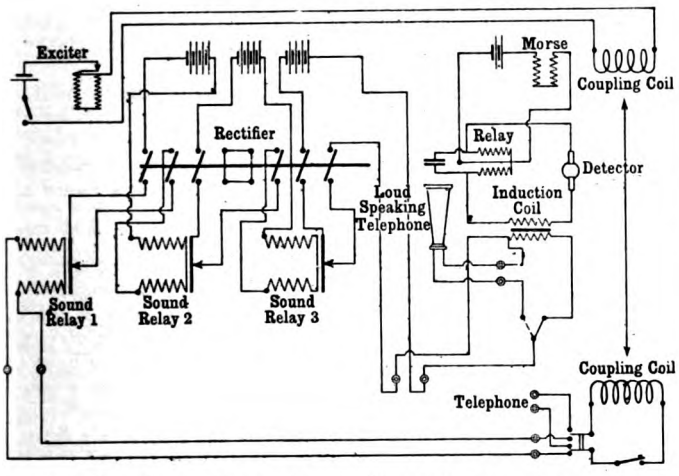

FIG. 11.—CONNECTIONS FOR THE MORSE INSTRUMENT ON THE SINGING SPARK SYSTEM.

does not exceed 1,000 ohms. By a sound of 1,000 ohms is meant that when a coil of 1,000 ohms is connected in parallel with a telephone of 1,000 ohms resistance the latter becomes inoperative. With a sound dissonance of about 5 per cent. a primary sound of about 500 ohms is necessary in the amplifier, and with a dissonance of 20 per cent. 100 ohms are necessary; that is, very much more primary energy is required. Practice has shown that sounds of only 500 ohms can be increased for as long as desired, thus proving that the frequency of the sparks, clearness of tone and constancy of the sender are extraordinarily high. To increase the selection an acoustic arrangement is used as well as a mechanical one. The loud-speaking telephone has, instead of the usual mouthpiece, a continually variable acoustic resonator in the shape of a tube which can be drawn out, as shown in Fig. 9.

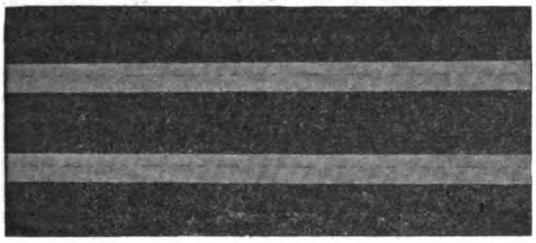

FIG. 12.—TWO TELEGRAMS RECEIVED BY THE MORSE APPARATUS.

The sound amplifier can be arranged to work as in Fig. 10, with a Morse writer, which had disappeared from wireless telegraphy together with the coherer.

The arrangement of connections at present used by the Telefunken Co. is shown in Fig. 11. The current flowing through the microphone contacts of the three amplifiers is composed of direct current and superposed current pulsations. This current passes through a telephone transformer, from which ordinary alternate current is obtainable. An electric valve connected in this circuit transforms this current into a pulsating direct current, and by means of this arrangement a highly senstive polarised relay is worked which operates the local current for the Morse instrument.

I have taken the opportunity in this lecture to show for the first time that double receiving by means of a receiving apparatus in connection with two senders using equal wave-length is possible. The senders differ only in that their tones vary by 20 per cent. At the receiving station the sender oscillations are picked up at the same time by a detector, and the receiving current passes through two primary windings connected in series and tuned in accordance with the sounds. One of these works with a higher, and the other with a lower, sound. Telegrams can thus be distinguished by sound as well as on the Morse instrument. The Morse dots and dashes were during receiving projected on the wall. Fig. 12 shows tests of this arrangement.

We have, in fact, in certain cases used a receiving station to collect three messages at the same time, using a high frequency and both mechanical and acoustic resonance. By this arrangement any fear of disturbance from outside conditions is nearly prevented, and I am of the opinion that by the use of sound arrangements a great improvement in the selection will be made in the near future, and a very important step forward will thus be taken.

TRAMWAY ECONOMICS.*

BY J. R. SALTER.

Summary.—The author here deals with the relationship between the receipts, car-mileage and working expenses of a tramway undertaking and the general commercial principles involved in its operation. A basis of comparison for the results obtained on different undertakings is discussed, and also the point at which the construction of a tramway is justified. The author considers that up to a 30-minutes service, tramway undertakings need have no fear of being replaced by self-propelled vehicles unless the cost of operating the latter is halved or the carrying capacity is doubled without increasing the cost.

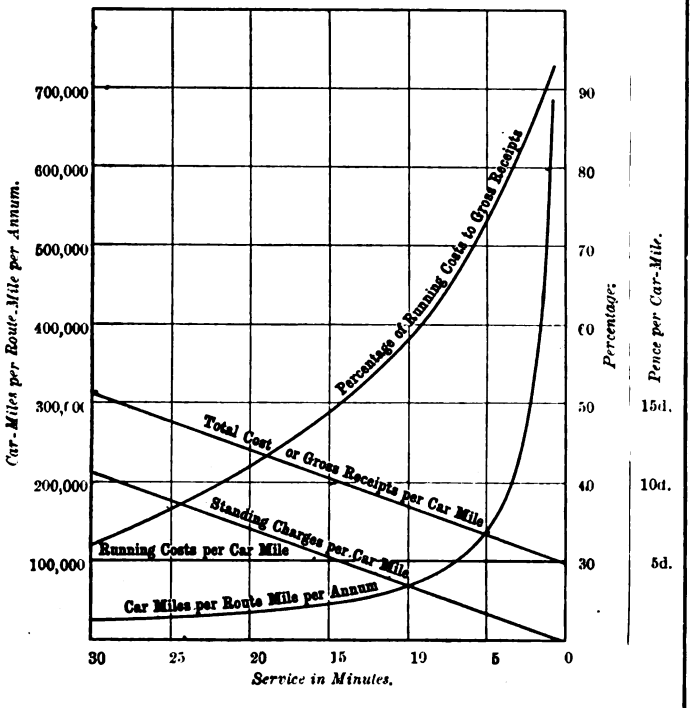
The expenses of operating a tramway, as indeed of almost any commercial undertaking, can be divided into two broad classes. There are, first, the "standing charges," which charges remain constant whatever the number of car-miles run may be; and there are the "running expenses," which are for all practical purposes proportional to the car-mileage run. The standing charges are those for interest, sinking fund and, partly, depreciation upon the capital cost of the equipment, whilst the running expenses are those for traffic, general expenses, power, maintenance of cars, track, overhead equipment and cables. To electric supply engineers the necessity for basing the charge for a given supply upon the cost of giving that supply has long been realised, this principle being enunciated by the late Dr. John Hopkinson in a Paper read in 1892. Dr. Hopkinson contended, taking the Metropolitan District Railway as an example, that as that railway must be prepared to bring in its thousands of passengers to the City at the beginning of the day, and to take them back in the evening, and for the rest of the day it must be content to be comparatively idle, it would not be inappropriate to charge more for carrying a person in the busy time than in the slack time, as it really cost more to carry him. This may be a general statement of the operation of the principle involved, but I venture to suggest that it has not full application in the case either of a railway or a tramway, for the reason that in these undertakings a very great proportion of the capital charges to which the standing charges belong must of necessity be incurred whatever the service may be, and that the only capital expense which is separately incurred for dealing with the heavy traffic is the cars and the power plant for driving them. In a tramway undertaking, too, the supplier may, by increasing his supply—*i.e.*, the number of car-miles run—provide an extra inducement to his customers or passengers, whilst in an electric supply undertaking, the consumer must be first obtained before the supply can be increased. Further than this, although probably the cars are idle for a great portion of the day, during the "rush" hours they actually provide themselves with an extra return owing to the very much higher receipts obtained per car-mile during those periods.

The diagram herewith shows the relation between the number of car-miles run per route-mile per annum and the service in minutes. The ordinates represent the car-miles per route-mile per annum, the abscissæ the services in minutes, the car-miles per route-mile per

* Abstract of a Paper read at the Congress of the Tramways and Light Railways Association at Dublin.

Digitized by Google

annum being on the basis of a slightly under 16-hour-day, in order to get approximately round figures for the different services. There is also shown in this diagram the proportional or running cost per car-mile, the standing charges per car-mile, and the total cost of operating or equivalent gross receipts per car-mile necessary to obtain a given result. The running costs per car-mile have been assumed at 5d., whilst the standing charges have been assumed at £1,000 per route-mile per annum. The figures which have been assumed are, of course, only general in their application, but may be taken as average figures which can readily be modified to suit any particular system, and they are intended to apply to a case where the undertaking generates its own supply of electricity. If the electrical energy is purchased, and the price is based upon the working costs at the power station, plus a charge for the plant capacity used for giving the supply, then the running costs may still remain the same as in the case when the supply is generated by the tramway undertaking; but if, as is more often the case, there is a fixed price per unit which is more or less independent of the car-mileage run, then the capital charges on the electricity portion of the undertaking become, so far as the tramway undertaking is concerned, a proportional or running charge. It may here also be pointed out that the increase in the number of the car-miles run by no means involves a proportional increase in the plant capacity required to give a supply to the tramways, since the greater the service the less the fluctuations upon the power station, and consequently the better the load factor. The charges have been worked out on the route-mile basis, and not upon the track-mile, for the reason that a given service, of course, remains the same whether the track be single or double.



It will be seen that there is a critical point in the service at which the standing charges per car-mile are equal to the running costs per car-mile—viz., at a 14 minutes' service. Again, the increase in the total costs per car-mile above the critical point is very much more rapid than is the decrease in the total costs below the critical point, and in consequence, the more frequent the service, the less important do the capital charges become. Probably one of the most interesting features is the percentage which the working or running expenses bear to the total receipts; the total receipts in this case being assumed as the same as the total costs, or, that is, sufficient to meet the capital charges upon the undertaking on the basis adopted.

I have always thought that the relationship between the working expenses and the gross receipts expressed as a percentage was of no practical value, and gave no idea of the commercial value of the undertaking. The working expenses in most tramways vary so slightly that the percentage between these and the receipts depends entirely upon the receipts, and as it has been shown that, with an increase in the number of car-miles, the receipts per car-mile can be rapidly diminished to obtain the same result, it is evident that no idea can be formed of the remunerative capacity of the undertaking from this relationship. It is apparent that with the rapidly increasing capital charges due to the reduction in the service, and with a practically constant running charge, the less frequent the service the less is the proportion or percentage of the working expenses to the total costs or equivalent gross receipts; and, as a corollary, the more frequent the service, the greater is the percentage of the working expenses to the gross receipts to obtain a given result. It would seem, therefore, from a consideration of these points, that tramway undertakings must look rather to an increase in the gross receipts by increasing the car-mileage and thus reducing the standing charges than to a reduction in the working expenses to improve their financial position. This dictum was advanced, I believe, by Mr. H. Mozley, manager of the Burnley Corporation tramways, in October, 1903, but was not given that credence which a close investigation of the problem seems to entitle it. The diagram shows the error of striving after high receipts per car-mile which one so frequently finds. In the case of one undertaking, where the number of car-miles per route-mile per annum was of the order of 60,000, being equivalent to an average 11 minutes' service, and with receipts of 10·3d. per car-mile, the service was reduced to 52,000 car-miles per route-mile per annum, increasing the receipts per car-mile to 11·53d., and in consequence, increasing the loss on the undertaking from £2,000 to £6,000 per annum.

In the foregoing considerations, the number of car-miles per route-mile per annum seems to be the determining factor, and it is somewhat extraordinary that so little use is made of this factor. Objection has from time to time been taken, and justly so, to the car-mile as a comparable unit. Mr. J. H. Rider has proposed a figure of merit $= \frac{\text{Units per car-mile} \times 100}{\text{Average weight in tons} \times \text{average speed in m.h.p.}}$. This undoubtedly gives a true scientific comparison of the conditions, so far as the current consumption is concerned; but from a commercial point of view such a comparison is of little value, and I think if we take the number of car-miles per route-mile per annum divided by 10,000, and multiply this by the receipts per car-mile, we have a figure which the better enables systems to be compared from a commercial point of view. The number of car-miles run per route-mile per annum is, to my mind, so important that I think it is a figure which could well be introduced into tramway accounts, and if it is divided by 10,000 we could obtain what might be called the "density factor."

This, multiplied by the receipts per car-mile, would give a figure of merit which could be used for comparing different undertakings, if taken in conjunction with the capital cost per route-mile, whilst if it were multiplied by the difference between the receipts per car-mile and the working expenses per car-mile, it would give the relative financial value of the undertaking.

It may be objected that this basis of comparison does not take into consideration the speed, the weight of the car, or the seating capacity, but the seating capacity and the fares determine the receipts per car-mile, whilst the speed mainly affects the power consumption and does not alter the number of car-miles per route-mile per annum—the density factor. It is true that the portion of the standing charges per car-mile represented by capital invested in cars varies in inverse proportion to the average speed. With a low cost per mile (for everything except cars) this becomes of importance, but with heavy cost per mile (for everything except cars) it becomes of less and less importance. With an increase in speed, however, and consequent reduction in the number of cars, and in the standing charges upon the cars, it will be found that there is an increase in the proportional charges due to extra wear and tear and extra power consumption, and as the variation in the average speed on systems in this country is not very great, the number of cars affected by the speed has not been taken into consideration. It is interesting to note that the income tax authorities, as a result of the efforts of thiss Asociation, in fixing the allowances for maintenance and depreciation assumed as a basis the number of car-miles per mile of track per annum. They allowed a life of 16 years for a density factor of 10, of 14 years for a density factor of between 10 and 15, 12 years for a density factor of between 15 and 25, and offered to give special consideration to cases of a density factor above 25.

I may further point out that the density factor could be usefully employed to compare the cost per mile of construction. This brings me to a consideration of the question as to the point at which, having regard to the increasing capital charges, with a reduction in the service, the construction of a tramway is justified. We need only for this object consider what receipts per car-mile with a somewhat infrequent service are likely to be obtained. With a service of this character, and with the fares obtaining in this country, it is unlikely, except in very special circumstances, that the receipts per car-mile will exceed 11d.; this being the case, it would appear on the basis of the curves that an average 17½ minutes' service is in the neighbourhood of the limit at which a tramway undertaking can be remunerative. This limit, of course, may be increased if the capital cost of construction is reduced, or if the character of the undertaking will permit of higher fares than are generally obtained in this country.

Digitized by Google

Of course, this limit of a 17½ minutes' service at which a tramway undertaking can be remunerative, applies to the undertaking as a whole, and the results which may be obtained from an extension of an existing system, or even from the terminal ends of an existing system, should not be considered separately.

Having then arrived at the limit for a remunerative tramway undertaking, it may not be out of place to consider whether some other means of transit, such as motor omnibuses, or the railless traction system, can be utilised, as capital is largely absent from these later modes of transit. In considering this, however, it would be well to ascertain in what way the average receipts per car-mile on a tramway undertaking are obtained. We find almost universally that the traffic upon tramways is of a very varying character. There are what are known as "rush hours," when the traffic often taxes the utmost capacity of the undertaking, and, in addition to this, provision has to be made for week-end and holiday traffic. Were it not for the ample carrying capacity which a tramcar provides for dealing with this extra heavy traffic, it would, of course, be impracticable to earn the average receipts which are now obtained. In this connection reference is made to the traffic on the Liverpool Corporation tramways, showing the enormous carrying capacity which has constantly to be provided if average receipts of even 11d. per car-mile are to be obtained. In an inter-urban tramway where the mid-day traffic is not of so constant a character as is to be found in a large city, the variation in the carrying capacity required upon the system is of a still greater order. On the Liverpool and Prescot Light Railway the receipts vary from 3½d. to 26d. per car-mile, the average receipts throughout the year being in the neighbourhood of 9d. per car-mile.

In considering, therefore, any means of transit which is to be compared with a tramway undertaking, the enormous variation in the number of passengers to obtain given receipts must be taken into consideration, and provision must be made, if the same fares are charged, to deal with extraordinary or "rush" traffic. It would therefore seem, having regard to the fact that the carrying capacity of any self-propelled vehicle is only half the carrying capacity of a tramcar, that at least double the number of vehicles will have to be provided. With motor omnibuses it is unlikely that the expenses per car-mile will be less than 10d., and to compare, therefore, the expenses of running such a system with that of a tramway, the cost per car-mile for operating must be doubled to provide the seating capacity. Although, therefore, the motor omnibus is relieved from many of the capital charges which are so serious to a tramway with a small service, the working expenses are so high that this method of transit is not as remunerative as a tramway, even at a 30 minutes' service, the expenses per car-mile on a tramway at this service being 15·5d. and the expenses per double 'bus mile to obtain the same capacity being 20d. It must not, however, be overlooked that the provision of the two 'buses, or the splitting up of the capacity, would result in a very much quicker service, and would undoubtedly conduce towards increasing the number of passengers during the slack periods.

With the railless traction system, the carrying capacity is only about one-third of that of a tramcar, and the expenses on this system may be assumed at 5½d. per car-mile; but in this case, if we are to provide for the excessive carrying capacity to obtain the average receipts, we find again that the systems are incomparable until a 30 minutes' service is reached. We have, as before, the extra service due to the triplicate number of cars, with an inducement to extra travel, but too much importance should not be attached to this, for the reason that in places where a 30 minutes' tramcar service is not justified, a 10 minutes' railless traction service will still less be justified. This, therefore, leads one to the conclusion that tramway undertakings need have no fear of being replaced by self-propelled vehicles unless the cost of operating them is reduced at least one-half, or unless, with the same operating costs, the carrying capacity can be doubled, until we arrive at a 30 minutes' service, assuming that the same fares are obtainable in each case. This conclusion may be modified by other considerations—that is, where the running of the omnibuses may obviate the necessity for changing cars, which becomes an important consideration, especially with an infrequent service. As an instance of a motor omnibus service which shows very gratifying results, the 'buses of the Scotch Motor Traction Co., which run in Edinburgh out to the Forth Bridge, are mentioned. Here, with a mileage of a little over 360,000 per annum, and with receipts per car-mile at 14·54d., very satisfactory results are obtained.

The clauses embodied in the Heywood Corporation Act, 1909, upon which through running between Bury, Heywood and Rochdale operates, are finally set out in the Paper. This is, I believe, the only instance in which detailed terms have been embodied in an Act of Parliament, and Mr. Stephen Sellon and myself were largely responsible for the drafting of these clauses.

CORRESPONDENCE.

INSTITUTION OF ELECTRICAL ENGINEERS ELECTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Will you allow me to make a few comments upon the recent election of the Council of the Institution of Electrical Engineers, from an entirely detached point of view.

The editorial criticisms in your paper and the comments made in a letter contributed to your columns show, to my mind, conclusively one thing, and that is that the alterations which were made in the Articles of Association of the I.E.E. in 1903 and 1904 do not quite meet the needs of the situation. If it is considered to be desirable that the general body of members should have a direct voice in the selection of candidates for office, the rules should provide that that choice can be exercised without offence being given in any quarter and upon terms which will make that choice equally effective with the choice made by the Council.

That the exercise of this choice should be interpreted by any members as involving a vote of want of confidence in the Council is most unfortunate, and yet, according to my experience, action under these rules always is so interpreted.

The chief criticism has been directed against the suggestion that the name of a particular nominee of the Council should be scratched out on the polling paper. We can all be agreed as to the unpleasantness of such a method of furthering the object in view, but it appears to me that it is the system of election which is at fault, and it, and it alone, must be directly blamed for all the unpleasantness.

If we analyse the situation without regard to any personal element, we find that, in effect, the general body of members are divided into two parties by any action taken under the rules relating to nominations made by members outside the Council. The division is between those who desire to support the Council and those who do not. Of course, in the abstract, this should not be the case, but speaking as one who has been hon. sec. of quite a number of clubs and societies, athletic and scientific, I have found that, among those who are sufficiently interested to vote at all, the voting all takes place on these party lines under such conditions. Now, if this be admitted, every supporter of the Council knows what nominee to scratch out on his polling paper, and knowing that, a little elementary mathematics will demonstrate that the supporters of the Council are placed at a great advantage compared with the supporters of the outside nominee unless the latter also agree among themselves which nominee to scratch out. The movement on the side of the Council is automatically organised, so that such voting power as they can command is concentrated to produce the best effect. If the conditions are to be equal the supporters of the outside nominee must also organise for the maximum effectiveness. I am not defending Mr. Chamen; those who know him realise that he would be incapable of acting otherwise than according to his conception of the highest standard of conduct in such matters, but I am concerned, and I am sure that you are, Sir, as well as others who have taken part in this discussion, that the most complete harmony possible should rule amongst the members of the Institution and its Council. It is upon that harmony that its vitality and well-being so largely depend.

I, therefore, plead for an alteration of the Articles of Association upon some such lines as those adopted by the American Institute of Electrical Engineers. I think that a "General Proposal List," made up from proposals put forward by all the members, from which the Council can make their own selections, might meet the case. As many of your readers will know, the "General Proposal List" is printed side by side with the directors' nominees in the case of the American Institute.

There will no doubt be some who will regard the arguments of this letter as consisting of a kind of specious sophistry, but

Digitized by Google

I trust that others will think differently, and that we may find a common basis of agreement which will strengthen the Institution of Electrical Engineers which most of us value very highly.—I am, &c., EDW. W. COWAN.

4, Queen Victoria-street, E.C.,
June 8th.

SHORT-CIRCUIT LOSSES IN ALTERNATING CURRENT COMMUTATOR MOTORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to Mr. Worrall's letter published in THE ELECTRICIAN, June 3rd, we wish to say that the experimental curves given in our Paper were determined both with ordinary brush holders and with those described by Mr. Worrall.

The results obtained with the different brush holders were quite the same when the necessary amount of care was taken in each case. So far as the aims of the work were concerned it was naturally quite immaterial what particular type of brush holder was used, and a description of the different types was superfluous. We intended to make a reference to Mr. Worrall's work, which, however, has only just recently been published, and, not knowing when it would appear, we were not in a position to refer to it. Moreover, at the time when our Paper was being written, Mr. Worrall was applying for a patent, and consequently a description in our work of his brush holder would have been out of place.

We take this opportunity to mention that the brush holder proved itself to be useful for experimental purposes.—We are, &c.,

Baden, June 7. A. FRAENCKEL.
B. J. M. LANE.

EFFICIENCY OF SHORT SPARK METHODS OF GENERATING ELECTRICAL OSCILLATIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to Dr. Eccles I should like to point out that if the efficiency of transformation from a primary oscillatory circuit to aerial is less than 20 per cent., then on disconnecting the aerial the primary current should not increase by more than 11 per cent., so long as the gap resistance remains constant. $\frac{i_1^2 - i_2^2}{i_1^2} < 0{\cdot}2, \qquad i_1 < 1{\cdot}11 i_2,$

Nor will the gap resistance change appreciably on account of so small a variation of current in the practice of wireless telegraphy. (N.B.—See also Rempp's observations, Fleming's "Principles of Wave Telegraphy," p. 186, Fig. 2.)

It follows that the loss in the primary circuit is Ki^2 for low and average efficiencies and that the simple formula

$$\frac{i_1^2 - i_2^2}{i_1^2}$$

is quite applicable.

For the particular case of high efficiency referred to by myself, I had experimental proof that the coefficient K remained constant for double the primary current if I am allowed to assume that the power consumed and emitted by a given aerial (having no gap), all conditions being identical, is proportional to the square of its r.m.s. current.

Indeed, on quadrupling the power supplied to the primary circuit, both aerial current and primary current doubled, which showed on writing the following proportion that K had not varied: $P - Kb^2 : 4P - K(2b)^2 = a^2 : (2a)^2$, P = power supplied to primary, b = primary r.m.s. current, a = aerial r.m.s. current.—I am, &c.,

Lyons, June 4. R. C. GALLETTI.

TELEPHONE RELAY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Many readers of Mr. Brown's Paper on the "Telephone Relay" must have felt that his modest claims are likely to be far surpassed. By its aid timid speakers at our meetings may soon hear themselves bellowing from the back of the hall, while politicians may be able to address audiences 100,000 strong by means of a number of instruments placed suitably, provided only that listeners turn up. Indeed, the relay may eventually do for hearing what the microscope has done for seeing. It may, therefore, not be thought intrusive to suggest a name. We have the ultra-microscope, which might be called the ultrascope, and this instrument might be called the ultra-microphone, or ultraphone, if a purer word be not discoverable.

The instrument provides an excellent example of the use of method in invention, about which I had the pleasure of giving a Paper some time ago. Working methodically on the problem, one would write down a list of every conceivable variety of contacts, solid, liquid, gaseous and vacuous. The mere fact of keeping such a list by one would be an inspiration in itself; people are so apt to keep to the kind of thing already in use that the idea of using a single small air-gap does not readily suggest itself to the mind working aimlessly. When giving my Paper someone challenged me to produce a relay. It was an awkward challenge, for evidently I would not be likely to give away a good idea at a meeting, whereas want of an answer looked like defeat. I did, however, think of the use of a homopolar dynamo, which will give alternating currents when excited with same, independently of the speed of revolution. Perhaps this might have developed to a practicable machine in the hands of, say, Mr. Brown, but it does not now seem to be wanted.

Could any of your readers give details of the other relays in use? These were mentioned in the discussion, but not described—Yours, &c.,

North Shields, June 3. C. TURNBULL.

LEGAL INTELLIGENCE.

Home Office Regulations for Electricity Works.

In the Sheriff Court, Hamilton (N.B.), on Thursday last week the Clyde Valley Electric Power Co. were charged with having had on March 3 last, in their electrical sub-station at Cambuslang, extra high-pressure conductors in the switchboard passage ways from the front and from below, so that it was not adequately protected while dangerous work was being done by one James Noble, an electrician's labourer; also, with having failed to make such switchboard dead, or to separate the section of such board by removal screens while repairs were being made by a person without technical knowledge or experience, in consequence of which the said James Noble was killed.

An agent from Messrs. Wright, Johnston and Mackenzie, writers, pleaded guilty on behalf of respondents, and asked the Sheriff to dismiss the case with an admonition or the imposition of a nominal penalty. He stated that it was impossible to make the switchboard dead, as the current was running continuously. With regard to screens not having been provided, he said it was the company's practice in the past to provide screens, and the responsibility for their use rested with the engineer in charge. In that instance the work was being carried through without the cognisance of the company. It was also explained that Noble had served his apprenticeship as an iron turner, had been in the employment of electric supply companies for some time, and had been employed at the erection of a sub-station at Catheart, which was completed in 1906 in compliance with the then existing regulations. Since then, however, the Home Secretary had prescribed further regulations which had only come into force on January 1, 1910.

The FISCAL explained that his instructions from the Home Office were, in view of that being the first case in Scotland, to press for a penalty which, while not severe, would yet be more than nominal. As to the Regulations only having recently come into operation, he pointed out that they had been drawn up after long negotiations with the various industrial companies, including the Clyde Valley Co. The room in which the accident occurred was a small one (14 ft. square) and passing through it there was a current of 11,000 volts.

Sheriff THOMSON said those accidents were becoming lamentably frequent. He thought the ends of justice in this case would be served if a penalty of £20 was imposed. Judgment accordingly.

Osram Lamp Works (Ltd.) v. G. M. Boddy & Co.

This action was before Mr. Justice Parker on Friday last upon interlocutory motion.

Mr. WALTER, K.C., representing plaintiffs, said he was instructed to move for an interim injunction to restrain an alleged infringement of patent, but defendants had raised the defence of non-infringement and invalidity, and he agreed it was not a case that could be usefully gone into on interlocutory motion. Defendants had undertaken to keep an account and on that undertaking he was willing that there should be no order on the motion except that the costs of the motion be costs in the action.

Mr. H. T. TERRELL, K.C., appeared for defendants and gave the undertaking mentioned, and his lordship accordingly made an order as agreed.

Re Sunderland District Electric Tramways (Ltd.); Capes v. The Company.

On Thursday last week Mr. Justice Swinfen Eady appointed Mr. Charles Eves, C.A., receiver and manager of the property charged by the first mortgage debentures of this company.

Mr. Micklem, K.C., for plaintiffs, said the company was formed to construct and work a tramway from Houghton-le-Spring to Sunderland. There were £160,000 of first mortgage debentures outstanding and £20,000 of second mortgage debentures. The company had been carrying on business for the last eight years, and always at a loss. No interest had been paid on the preference shares, of which there were £90,000, or on the £74,000 ordinary shares. Though no interest on the debentures was in arrear, it was admitted that there would not be sufficient to pay the interest which became due on July 1 next.

The company, the second debenture holders and trustees for first debenture holders all consented to the order.

Price Bros. v. Cuban Telephone Co. (Ltd.) and Others.

Mr. Justice Parker had before him a motion by plaintiffs for an interim injunction to restrain the second defendants (Messrs. Chaplin, Milne, Grenfell & Co.) from paying over to the first-named defendants £3,864 in their hands.

Mr. Mark Romer, who (with Mr. Howard Wright) appeared in support of the motion, said that the sum was paid to Messrs. Chaplin, Milne & Co. by plaintiffs in payment for 5 per cent. first mortgage bonds issued by the Telephone Co.

Counsel for the second defendants said they were willing to give an undertaking until the trial of the action.

Mr. Wright, for the Telephone Co., said that he would give an undertaking until the trial if the aspersions were withdrawn.

Mr. Romer said that he could not withdraw them at this stage.

His Lordship suggested that the defendants should give the undertakings proposed until the trial, "not admitting the allegations in plaintiffs' affidavits," and that was acceded to.

Babcock & Wilcox (Ltd.) v. Water Tube Boiler & Engineering Co. (Ltd.) and E. Danks & Co. (Oldbury) (Ltd.)

On Monday Mr. Justice Warrington had in his list an action brought by plaintiffs for alleged infringement of patents, but Mr. Colefax (led by Mr. A. J. Walter, K.C.) said the action was launched at rather an early date, and they felt they were not at present in a position to put the case before the Court upon their claim. Their evidence was in such a state that they would not be justified in occupying the time of the Court. But there was a counter claim for revocation.

His Lordship: You submit to have judgment against you on the claim?—Yes.

Mr. Bousfield, K.C., who appeared (with Mr. Gray) for defendants, said the counter claim was put in as part of the defence. He had not had time to consider the matter as it now stood, but he would be averse from fighting these three patents in the face of plaintiffs withdrawing their case. It was practically equivalent to a discontinuance of the action. His Lordship would see that the counterclaim would never have been put in except for the allegation of the plaintiffs that upon the construction of the patent defendants were infringers. He suggested that defendants should be allowed to withdraw the counterclaim, and that each party should pay their own costs in respect thereof.

Mr. Walter said he thought is was an entirely unwarranted counterclaim.

His Lordship said this was an action for infringement of certain letters patent. There were two actions, which were consolidated, and were against different defendants. After reviewing the facts he considered the proper method of dealing with the matter was: The plaintiffs, not asking for judgment in the action and defendants not asking for judgment on the counterclaim, the action be dismissed, with costs, and the counterclaim, with costs.

Compensation Claim for Miner's Death.

Sheriff Thomson (Hamilton) has concluded proof in a case in which compensation is claimed by relatives from Messrs. Archibald Russell (Ltd.) in respect of the death of a miner (John Wallace) killed in Dechmont Colliery, Cambuslang, by coming in contact with an electric cable in the underground workings of the colliery.

David Wallace, night oversman at the colliery and a brother of deceased, said he had authority from the management, if there was a pressure of oncost work, to take ordinary miners from the coal face to render assistance so as to expedite the general working of the pit. On the night of the accident the oncost staff were making excavations in a chamber in which it was proposed to instal an electric motor. Due to the blasting a mortar board used by the bricklayers was badly damaged in the course of the shift. Witness suggested to deceased that he might fill up the time for the remainder of the shift by doing certain work, including lending a hand in repairing the mortar board. Three electric lights were fitted up in the chamber, but only one was lighted. Two of the terminals were thus exposed, while a cable was coiled up and hung on a prop close to the engine seat. While the hutches of sand were being slewed on an iron plate witness heard his brother utter a cry. Instinctively believing that the cable was to blame for the accident witness took off his cap and pulled the coil down from the prop. His brother was almost instantaneously killed. The only theory he could put forward as to the cause of the fatality was that deceased while removing the hutches had come in contact with a live wire.

Prof. John Glaister said he had seen a piece of cable which was used in Dechmont Colliery on the night of the accident, and since the wires were exposed he thought its condition was such as to cause a shock to any man coming in contact with it. He was aware that that chamber was heated, and it was an established fact that sweated hands offered much less resistance to electricity than dry hands. He knew cases where current of a similar voltage to that in the pit (230) had caused death.

Alex. Mathie, electrician in charge of the electric plant in No. 1 pit Dechmont Colliery, said that on the day previous to the accident he removed two of the three arc lamps, but he left the terminals exposed. The cable was coiled upon a prop about 4 ft. 6 in. from the ground. The distance of that prop from the iron plate where deceased was working with the hutches would be from 2 ft. to 3 ft. He agreed that a person coming in contact with a piece of cable in which the wires were exposed would receive a shock. He was not qualified to say whether that voltage would cause death to a man who was perspiring freely on an iron plate, because as a matter of fact he had himself received a higher voltage than that.

Defendants' case was that deceased, being a miner, ought not to have been taken from the face to do such oncost work as removing hutches of sand and a water-chest; that there was no immediate urgency to justify the employment of deceased at that work, and that, moreover, the whole task of shifting the hutches could have been completed in little more than 10 minutes.

Judgment was reserved.

Wakefield & District Light Railway Co. v. John Sharphouse & Co.

At Wakefield County Court on Tuesday Judge Greenhow heard this action, in which plaintiffs claimed £6 damages from defendants for obstruction to their line.

The case for plaintiffs was that on Feb. 2 last Messrs. Sharphouse's motor waggon broke down on plaintiffs' track between Lofthouse and Leeds, and there was a total or partial obstruction for 50 minutes. The motor waggon was got going again in the direction of Lofthouse, but broke down again, causing further obstruction for an hour. When the line was totally obstructed passengers had to be transferred, and the cars reversed, and when the obstruction was confined to one line the cars went back to a bye pass and thus crossed over. The car traffic was greatly disorganised, and much inconvenience caused. There had been numerous prior breakdowns of that motor waggon.

Mr. Shepherd, for defendants, urged that unless it could be shown that defendants ran a motor waggon which they knew would break down and delay the traffic there was no case to answer. This breakdown was an accident. There had been several prior accidents, but none of these was caused by the motor waggon being defective.

After hearing evidence, his Honour said he could not find there had been negligence, and he entered judgment for defendants, with costs.

MUNICIPAL, FOREIGN & GENERAL NOTES.

APPOINTMENTS VACANT AND FILLED.

Applications are invited for the vacant posiiton of assistant lecturer and demonstrator in the physics department of the Technical School, Sunderland. Salary £150 per annum. Applications to the secretary to the Education Department, Mr. T. W. Bryers, 15, John-street, Sunderland, by Tuesday, June 21. See also an advertisement.

A first-class electrical engineer is wanted, with experience in the design of c.-c. machinery. See advertisement.

A machine draughtsman, experienced in a.-c. and d.-c. works, is required by the Electric Construction Co., Bushbury Works, Wolverhampton. Applications to the manager. See an advertisement.

Applications are invited for the position of borough electrical engineer at Salford. Salary £500 per annum, rising to £700. Applications to the town clerk, Mr. L. C. Evans, by June 13.

The Council of the University of Manitoba, Winnipeg, Canada, require a lecturer in electrical engineering. Salary $1,500 a year. Applications to the Registrar by June 25.

Kent Education committee require an assistant master in the electrical engineering department of the Technical Institute, Gillingham. Forms of application from Mr. J. Thompson, Town Hall, Chatham, and applications to the Director of Further Education, Mr. R. L. Wills, M.A., Technical Institute, Gillingham, by June 20.

Hull Education committee require a chief lecturer on engineering for the Municipal Technical College. Commencing salary £250. Forms from the Secretary, to whom applications by June 17.

An assistant engineering lecturer is required at Coventry Municipal Technical Institute. Salary £150, rising to £180. Forms from the Secretary. Applications by June 14.

Professors of engineering, chemistry and mathematics and physics are required for Queensland University. Salary, in each case, £900. Applications to Agent-General for Queensland, London, by Aug. 31.

Digitized by Google

Bermondsey (London) Council want a man to take charge of public arc lamps. Wages £2. 5s. Applications by June 17 to the Town Clerk.

Mr. Chas. Merrall has been appointed engineering clerk of works at the new asylum, Colchester.

Mr. G. J. Walmsley, M.Sc., of the Grammar School, Ashbourne, has been appointed lecturer in mathematics at the Municipal Technical Institute, Belfast.

Dr. F. Gnauth has been appointed general manager of the Felten & Guilleaume-Lahmeyerwerke, A.-G., Mülheim-on-Rhine.

EDUCATIONAL NOTICE.

City and Guilds of London Institute.—The entrance examinations of the City and Guilds Central Technical College, Exhibition-road, and the City and Guilds Technical College, Finsbury, are held in September, and the sessions commence in October.

Both institutions provide courses of instruction in engineering, chemistry, mechanics and mathematics, &c. Particulars of entrance examinations, scholarships and courses of study may be obtained from the respective colleges or at the head offices of the Institute, Gresham College, Basinghall-street, London, E.C. The Central Technical College is intended for higher technical instruction for day students not under 16 years of age, preparing to become civil, mechanical or electrical engineers, chemical or other manufacturers and teachers. The college is a school of the University of London, and forms the engineering section of the Imperial College of Science. The courses of the study for the associateship of the Institute cover a period of three years. The Finsbury College is designed for day students preparing to enter engineering and chemical industries and for those who have already served an apprenticeship and also for evening students. The day courses in mechanical or electrical engineering cover two years and those in chemistry three years.

Accrington.—On the recommendation of the Electricity committee £550 has been appropriated out of the past year's profits on the electricity works to a relief of rates.

Aldershot.—The Council have applied for sanction to a loan of £2,000 for extensions of the electricity supply cables, &c.

Argentina.—The "Review of the River Plate" states that a company has been formed at Olavarria with a capital of $200,000 to acquire Mr. A. Brumana's concession for electricity supply.

The Cia. de Electricidad de la Provincia de Buenos Ayres have purchased the Mar del Plata electricity works of the Cia. de Electricidad del Plata for $1,000,000 (m.n.) of which $300,000 is to be paid in cash, $610,000 in 6 per cent. bonds and $90,000 by a mortgage taken up by the purchasing company.

The Red Telefonica del Norte, Ltda., has been formed to acquire the telephone system of Herdalo & Co. at Colon and the extensions to the Pergamino and Rojas districts, and also to connect all the northern districts of Buenos Ayres and the southern districts of Santa Fé with Rosario, Buenos Ayres, &c.

Atlantic Cable Rumours.—We have received the following note in regard to certain statements published in the daily journals:—

One or two London newspapers have questioned the correctness of the statement made by the President of the Commercial Cable Co. (Mr. Clarence H. Mackay), in which he denied the existence of any foundation whatever for the rumours of a combination between the Commercial Cable Co. and the Anglo-American Telegraph Co. The Vice-President and General Manager of the Commercial Co. (Mr. George G. Ward) emphatically and positively reiterates all former statements that neither the Commercial Cable Co. nor the Postal Telegraph Cable Co. (its landline connection in the United States) have ever contemplated, or now contemplate, such combination or any other.

Australasia.—The residents of Hay (N.S.W.) have endorsed the proposal of the Town Council to light the town electrically and use electric power at the waterworks and sewage works.

A committee has been formed at Toowoomba (Queensland) to promote an electric tramway scheme. The manager of the Toowoomba Electric Lighting Co. (Mr. A. Gibson) has prepared estimates of cost, &c.

Geelong (Victoria) local telephone system is being re-arranged by the Postmaster-General's department, and a new switchboard framework is being installed. A further improvement will shortly be made by the adoption of a modern branching multiple switchboard.

Austria-Hungary.—Agram Municipality are purchasing additional plant for their electricity works at a cost of about 420,000 kroner (£17,500).

Aussig municipal authorities are about to construct an electric tramway from Pokau to Tellnitz.

Battersea (London).—Subject to the L. & S.W. Rly Co. bearing cost of work, services are to be laid to four of the company's signal cabins for electrically operating the signals at an estimated cost of £296. 5s.

Bethnal Green (London).—Last week the Council were again recommended to take steps to afford to occupiers of premises within the borough a supply of electricity by entering into an agreement with Shoreditch Council, on the basis of the alternative flat rate scheme of the latter authority, for seven years. The recommendation was adopted by the casting vote of the Mayor.

Bognor.—The Chichester Electric Light Co. will apply for a provisional order.

Bournemouth.—On Tuesday the Council referred to a committee of the whole Council a recommendation from the Tramways committee that, subject to approval of the Board of Trade, the present conduit system in the centre of the borough be abandoned and the overhead system substituted.

Braunton.—The Parish Council which is negotiating with Edmundson's Electricity Corpn. for the electric lighting of the district, has decided to consult an electrical engineer on the proposed scheme.

Bridlington.—The Council have decided to carry out further electrical illumination work at a cost of £200.

Burnley.—The Electric Tramways committee have decided to purchase two tramcars at £753. 13s. 6d. each.

Camborne.—The Urban Electric Supply Co. have submitted to the Council details of a scheme for supply of electricity for power in this and adjoining districts. Overhead cables will be employed, and the proposed route has been sanctioned by the Highways committee.

Canada.—An electric railway from False Creek to Point Grey and New Westminster is to be constructed by the Vancouver-Westminster Terminal Railway Co.

Carlisle.—The Council will apply for a provisional order to extend the electricity supply area into the rural districts.

Costa Rica.—A private company has obtained a concession for the electric lighting of the Port of San José.

Coventry.—On Wednesday an inquiry was held into the application of the Corporation to borrow £54,200 for extensions of the electricity supply undertaking.

Part of the proposed loan was stated to be to cover cost of obsolete plant and part for new plant, there being applications for power from the Daimler Motor Co. and other manufacturers, and it was estimated that the proposed expenditure would be sufficient for five years. The town clerk (Mr. G. Sutton) gave a sketch of the financial position of the undertaking, and said the Council had adopted the policy of endeavouring to sell the current at such a low figure as would attract customers and it was intended to reduce the charge to both manufacturers and private consumers.

Cuba.—The "Chamber of Commerce Journal" states that the average annual value of the imports of electrical machinery into Cuba from 1905 to 1907 is officially stated at $70,000.

Of this the U.S.A. sent $50,000 worth, and the U.K. $18,000. Electric lamps imported averaged $40,000 per annum, of which the U.S.A. supplied $24,000 and Germany $10,000 worth. Dynamos from 10 kw. to 50 kw. and single phase motors of ¼ to 7 H.P. are most in demand. There is an opening for metal filament lamps. The best means of securing business is to appoint a tr veller speaking English and Spanish, and representing one or more firms, and to establish a depot at Havana, it being practically useless to canvass for orders by correspondence, as the country is well worked by Americans and Germans.

Customs Duties.—A recent supplement of the Customs Tariff Guide states that the following duties are leviable (according to recent decisions) on wireless telegraph plant imported into the Australian Commonwealth States:—

Stepdown transformer, induction coil (for a.c. motor), variable coil (for a.c. motor), motor (under 200 H.P.), resistance coil, impedence coil (for a.c. motor), and resistance starter 20 per cent., ad val. (for British or foreign goods); spark gap, receiving instrument, morse key, leyden jars, high frequency protector, lightning arrester, and zinc insulators (so-called) 17½ per cent. for foreign and 10 per cent. for British goods; porcelain insulators, 25 per cent. (British 20 per cent.); ammeter, 5 per cent. (British free); voltmeter, switches, cut-outs, and wire, n.e.i., free (British or foreign).

The following are import duties under the Tariff which has been approved by the Japanese Diet, and come into force on a date to be fixed by Imperial Ordinance:—

Insulated electric wires, armoured with metals (other than submarine): Combined with india-rubber or gutta-percha, 11 yens per 100 kin (19s. per cwt.), ditto, not combined with rubber or gutta-percha, 5·50 yen per 100 kin. (9s. 6d. per cwt.); flexible cords combined with silk, 25 per cent. ad val; ditto not combined with silk 18 yen per 100 kin (£1. 11s. 1d. per cwt.); other electric wires, combined with india-rubber or gutta-percha 14·50 yen per 100 kin (£1. 5s. 0½d. per cwt.); ditto not combined with india-rubber or gutta-percha, 25 per cent. ad val; tyres for locomotives and other vehicles, running on rails, 1·50 yen per 100 kin (2s. 7d. per cwt.); parts of automobiles, excluding motive machinery, 30 per cent. ad val.

Digitized by Google

Darlington.—In future, theatres and music halls, which are not likely to make a large demand on the electricity works until after 6:30 p.m., and which use not less than 10,000 units per annum, are to be charged at a flat rate of 2½d. per unit for lighting.

Dundee.—The additions to the public baths are to be wired at a cost of £129. 15s.

Eastbourne.—The L.G. Board has sanctioned the borrowing of £1.835 for condensing plant.

Edinburgh.—The electric tramway from Ardmillan-terrace to the new markets at Gorgie was opened for traffic on Wednesday.

Electricity Supply in Hanley.—Mr. C. H. Yeaman, chief electrical engineer at Hanley, forwards a pamphlet which he is issuing in pushing the claims of electricity in that town. The first few pages give some very good reasons why electricity should be used rather than gas, and two illustrations show what has been done in the way of lighting in that town. The remaining pages of the booklet are on power supply, and consist principally of illustrations showing where and for what purposes motors are being used in Hanley.

As might be expected, pottery works figure largely amongst the consumers, though such apparatus as sausage-making machines are also to be found. The book, in general, is excellently got up, and if there is one criticism to make it is that the paper used should in future be of rather better quality, as the half tone blocks do not come out quite so well as they might.

Exhibitions.—The fourth annual Business Exhibition will be held at Olympia, London, from Oct. 13 to 22 next. Particulars from the Secretary, 2, Breams-buildings, London, E.C.

At the British Consulate at Colima (Mexico) a room has been set apart for the exhibition of specimens and samples of British goods. These must not be large and must be accompanied by cards giving prices and address of exporter or agent.

Particulars may be obtained from Signor R. Martinenghi, Societa Mostra Politecnica, Milan, as to charges for space, &c., at the Permanent Technical Exhibition at Milan.

Felixstowe.—Some time ago the Council applied for sanction to a loan of £4,500 for a Diesel oil engine, dynamo, &c., but before complying with the request the L.G. Board ask that the balance of £2,636. 18s. 3d., borrowed under the authority of previous sanctions and not spent, should be invested in authorised securities and treated as a sinking fund.

France.—A concession for constructing and working about 88 miles of tramways at Bayonne has been granted to a French company.

Frome.—The Council have decided to transfer their electricity undertaking to Edmundson's Electricity Corpn., which has hiterto worked it on lease, the Council providing the capital and paying interest and sinking fund charges.

German East Africa.—The "British and South African Export Gazette" states that a 30,000 H.P. plant is required in connection with the projected electric power installation at the Pangani Fields.

Grimsby.—The Lighting committee recommend the Council to apply for sanction to borrow £4,000 for mains extensions and £1,500 for services.

Holland.—An application has been lodged for a concession for electric tramways from the Hague to Leyden, via Wassenaer.

It is probable that Nijmegen Council will shortly take over and convert to electric traction the steam tramways of the Nymeesche Tramweg maatschappij.

India.—"Indian Engineering" says the Railway Board have sanctioned the commencement of the work of electric lighting and ventilation of the southern portion of the station buildings and two platforms at the Howrah station of the East Indian Railway.

In connection with the working of the Mysore Cauvery Falls power undertaking, the outlay on the scheme exceeded the budget grant for the past year (R.5,40,000) by R.10,33,040, owing to the adjustment of a sum of R.11,27,685 towards the new depreciation fund. Revenue during the year was R.17,46,295 and working expenses were R.2,97,000. Out of R.79,97,234 spent on the scheme up to June, 1909, a net revenue of R.56,11,697, or 70·17 per cent. of the capital expenditure, has been realised. The third installation of the works was practically completed during the year.

A proposal is before the Cochin Durbar to connect Tripunitrah, the seat of H.H. the Rajah's family, with Ernadulam by means of an electric tramway.

I.M.E.A. Glasgow Convention.—We are asked to state that the special arrangements made by the Electrical Press (Ltd.) for journeying to Glasgow from Euston next week is extended to all who are journeying by the 2 o'clock train on Monday, June 13. Saloons will be provided on that train, which, leaving Euston at 2 p.m., calls at Willesden at 2:10, Rugby 3:40, Crewe 5:55, Preston 6:18 and Carlisle 8:8. Apply immediately to Mr. W. Alderson Smith, 37-38, Strand, London, W.C.

Inquest.—An inquest was held on Friday into the death of Edward Abbott, who was killed at the Glamorgan Colliery, Llwynypia, on 1st inst.

The evidence showed that a haulier named Doel was driving a horse attached to two trams at the brickyard, when the horse fouled two stay wires supporting a derrick, and received an electric shock which killed it. Abbott was seen clutching hold of the hind tram, to which the horse was attached. The power was cut off at the power station, but it was found that Abbott was dead.

Mr. DUNCAN M'DONALD, electrical engineer, thought the accident was caused through the breakage of an insulator at the top of the derrick, supported by wire stays. The horse received a shock and fell against the stays. The stays attached to the derrick holding the electric cable were evidently affected by the broken insulator. A part of the rubber casing being broken caused a surface leakage, and it was evident that Doel's horse came within the influence of the leakage, causing it to plunge and fall across the stays.

The CORONER, in summing up, said the question was whether the system now working was a good one.

The jury returned a verdict of "Accidental death," adding that no blame was attached to anyone.

Islington (London).—The Council have decided to obtain the opinion of Sir Alex. Kennedy, at a fee of 50 guineas, on the report of the borough electrical engineer (Mr. A. Gay) recommending an increase of the capacity of certain of the electric supply mains.

Italy.—The Ministry of Public Works have approved the application of Andreucci, Allegra e Cia for a concession for the construction and working of an electric railway from Rome to Nettuno, via Anzio.

Japan.—The Musaski Electric Railway Co. have obtained a charter to construct an electric railway on the standard gauge from Yokohama to Tokio. It is stated that this will be the first standard guage railway in Japan.

Kent Tramway Scheme.—Maidstone Corporation are considering a scheme for constructing an electric tramway between Maidstone and Chatham, a distance of nearly 7 miles. It is estimated that the cost of the scheme would be £60,000, and the yearly net profit about £2,000. The consulting engineer is Mr. S. Sellon.

Leyton.—The engineer and manager of the Lea Bridge Gas Works has applied for a supply of electricity for a 7 H.P. motor at the gas works for increasing the pressure of gas, and having regard to the fact that the motor will be chiefly used in the evening, a charge of 4d. per unit is to be made for current.

Mr. D. H. Boggis-Rolfe, district auditor, has made various recommendations, in his report on the accounts of the tramways and electricity supply departments for the year ended March 31, 1909, and especially in regard to the keeping of stores.

The Electric Light committee, while admitting that improvements, to secure which steps have now been taken, may be effected they are unable to agree with the auditor's conclusions.

Lincoln.—At the meeting of the City Council on Tuesday it was reported that the net profit on the electricity undertaking during the past year was £2,503, or £5 less than in 1908-9, and on the tramways a deficit of £44.

Metropolitan Association of Electric Tramways Managers.—A meeting of the members of this association was held on the 3rd inst., at the offices of the Metropolitan Electric Tramways, Ltd. (Finsbury Park, N.). Among those present were: Messrs. H. E. Blain, West Ham (acting chairman), F. Schofield (Leyton), C. Mittelhausen (Bexley), Mr. Ullmann (East Ham), W. Murray (Walthamstow), T. B. Goodyer (Croydon) (hon. secretary), A. H. Stanley (managing director, London United Tramways), W. F. Hammond (Metropolitan Electric Tramways), and V. Mason (South Metropolitan Electric Tramways); W. Binns (Reading) being also present by invitaiton.

Letters regretting inability to attend were received from: Sir Clifton Robinson and Messrs. J. K. Bruce (L.C.C.), A. Covenay (Erith) and A. G. Balfour (Dartford).

The HON. SECRETARY reported that he had received further communications from America respecting the registration of accident claims; that, on request, he had supplied a schedule of the "Through running arrangements" in the metropolitan area to the Public Service Commission, Fourth District, New York, and that he had been invited to join, as representing the Association, a committee for the protection of electrical industries.

Mr. H. E. BLAIN explained the views of the hon. secretary and himself as to the preliminary course which should be adopted in connection with the proposed central bureau for the registration of claims, and the proposition was agreed to.

The company then left by special car (provided by the Metropolitan Electric Tramways, Ltd.) for a visit of inspection to the car repair works at Hendon. They were shown over the shops by Mr. J. Devonshire managing director of the company, and Mr. A. H. Pott, the chief engineer; and the members were extremely interested in the various appliances and arrangements which they inspected. Mr. Pott demonstrated

Digitized by Google

the methods used in the company's motormen's training school, by which the visitors were very much impressed.

Mr. BLAIN, on behalf of the association, requested Mr. Devonshire to convey the appreciation of the members to his fellow directors for their kindness in both facilitating the reception and also for kindly providing tea. He also thanked Mr. Pott for his courtesy in giving the necessary information in connection with the exceptionally interesting and instructive inspection just completed.

Mr. DEVONSHIRE suitably replied, and subsequently the members returned to London and were entertained to dinner by Mr. Stanley, who was accorded a hearty vote fo thanks for his hospitatty.

Middlesbrough.—The borough electrical engineer (Mr. H. M Taylor) has reported upon the present scale of charges for electric current.

In view of the future use of metal filament lamps Mr. Taylor thinks it unwise to make a general reduction in prices. He suggests that they should make a reduction this year to large consumers by reducing the price per unit after the first 1,000 units per quarter from 3½d. to 3d. A further reduction might also be made to theatres and music halls after the first 1,500 units per quarter from 3d. to 2¾d. per unit. The general use of metal filament lamps in theatres and music halls is impossible (continues Mr. Taylor) owing to the amount of vibration, and thus they were unable to obtain the reduced cost of light by which private consumers were able to benefit. Power charges should be reduced from 2d. per unit for 250 hours' use of the maximum supply demanded per quarter and 1d. thereafter, to 2d. for 200 hours' use and ½d. thereafter.

Mr. Taylor's suggestions have been adopted by the Electric Supply committee.

North Berwick.—Messrs. Crompton & Co.'s terms for the erection of electricity supply works were considered by the Council on Tuesday, but it was decided to adjourn consideration of the matter until a formal agreement is prepared.

Northampton.—The extension of the tramways to Far Cotton is projected at an estimated cost of £14,560.

Nuneaton.—The Council have decided to withdraw their application to the L.G. Board for sanction to a loan of £2,155, and to substitute an application for £4,804, so as to provide extensions of the electricity undertaking during the next three years.

Peterhead.—Recently Messrs. Jas. Simpson & Son asked the Council to allow an underground pipe to be laid to enable them to give a supply of electricity to a shop in the new post office buildings, but the Council insist, as a condition, that the firm must generate electricity by gas-driven plant, the town gas being used.

Rotherham.—The Council is to apply for sanction to borrow £27,832. 7s. for the electricity undertaking, including £10,000 for mains and transformers, £3,000 for a 1,000 kw. turbo-alternator, condensing plant and switchboard, £6,175 for 3½ miles h.t. feeder cable, £2,222 for feeder and distributor mains for Broom district, £1,050 for a 250 kw. rotary converter set, £1,172 for a 250 kw. transformer set and h.t. switchboard set (for generating station), and £975 for equipment at Howells, Wincobank.

Russia.—A German Consular report states that there is an increasing demand in the Saratoff district for electrical material and accessories, and the inhabitants evince a desire to have electric light in their houses.

Shoreditch (London).—The Council will give a bulk supply to Bethnal Green at one or more points on the boundary at the following rates:—

250,000 units per annum, and under 500,000, 1·15d. per unit; under 750,000, 1·1d.; under 1,000,000, 1·05d.; 1,000,000 and over, 1d., subject to a seven years' agreement and a coal clause providing for any rise or fall in coal to be followed by a corresponding rise or fall in charges.

Sheffield.—An inquiry was held on Tuesday into the application of the Corporation for sanction to borrow £78,207 for extensions of the electricity undertaking.

The Inspector (Mr. H. Ross HOOPER) said he understood the application was for the extension of the buildings at the Neepsend station and the installation of additional generating plant. At Neepsend the capacity was 7,000 kw., and at Sheaf-street 4,000 kw., total 11,000 kw., and the maximum demand last winter was 6,980 kw., which showed that there was barely sufficient plant to be able to meet the demand if anything happened to the 4,000 kw. machines. The estimated demand next winter would be approximately between 8,000 kw. and 8,500 kw. That being so, he thought it was clear that some additional plant was necessary, and the proposal was to duplicate all the existing large plant. They had five boilers at Neepsend, with a steam capacity of 155,000 lb. On that they had at present a load of 5,500 kw., and, taking that as a mean of 18½ lb. per kilowatt, there was necessity for additional boiler power. The buildings would be erected on land purchased for electric lighting purposes. They conformed to the by-laws, and the work would be carried out by contract. No tenders had been as yet invited. Continuing, Mr. Hooper said: "I told Mr. Fedden last night that the policy of the Board now in regard to these large applications for additional plant was, in the first instance, to approve the expenditure, but to defer the issue of sanction until furnished with an amended estimate based upon the tenders which had been accepted, their object being that the amount of the sanction should approximate as closely as possible to the expenditure, and thus do away with the old method of not having enough or having too much." Mr. Fedden had informed him that £7,450 would be required this year, and that, therefore, it was desirable for sanction for that amount to be given at once. When the tenders had been accepted for the buildings and plant an amended estimate would be furnished, and the Board would be asked to issue sanction on those lines.

The TOWN CLERK concurred, and said he could not do better than accept the outline of the position given by the Inspector.

The Electric Supply Committee have decided to reduce the price of electric current from 4d. to 2d. per unit.

Mains extensions are to be carried out at an estimated cost of £490.

The Glossop-road new baths are to be illuminated by incandescent electric lamps.

The tramway track in a portion of Attercliffe-road is to be relaid at a cost of £4,700, the centre poles are to be taken out, and span wire construction erected.

The old music hall in Surrey-street, which is being fitted up as a lending library and reading room, is to be wired by the electric supply department of the Corporation at a cost of £81. 9s. 6d.

South Africa.—The "British and South African Export Gazette" states that orders from South Africa have been placed with Butters Bros. & Co. (Glasgow) for electric cranes and with H. Simon Limited (Manchester) for electric motors.

Johannesburg Corporation are on the market for 1,000 5-ampere, 153 10-ampere, 80 20-ampere and 20 40-ampere meters.

The Consolidated Goldfields of South Africa will shortly require a number of electric pumps.

An electric pumping plant was recently imported for the Ruia Mine, Rhodesia.

Stevenage.—The Board of Trade are inquiring of the Council as to the steps taken to carry out the provisions of the electric lighting order of 1902.

Swansea.—The Electricity committee has discussed the possibility of competition with the Harbour Trust in the supply of electricity, and a conference is to take place on the subject.

The assessment of the electricity works has been increased from £1,300 to £3,300.

Warrington.—An inquiry was held on Wednesday into the Council's application for sanction to borrow £7,420 for extensions of the electricity works.

The deputy town-clerk (Mr. A. T. Hallaway) said the money was required for additional generating plant at the electricity station. There was an increased demand for current, and no extensions to the present buildings would be required, with the exception of a shed for the switchboard.

Technical details were given by the borough electrical engineer, Mr. F. V. L. Mathias.

Wednesbury.—The Council are recommended to apply for sanction to a loan of £4,600 for the extension of the plant at the electricity works.

The Council have received sanction to a loan of £2,858 for the electricity undertaking, viz., £1,300 to defray expenditure on mains from April 1, 1909 (loan to be repaid in 25 years); £750 for services (15 years), and £808 for meters, to defray excess expenditure up to April 1, 1909 (£208), and expenditure from April 1, 1909 (£600), the loan to be repaid in five years.

West Bromich.—The Council have applied for sanction to a loan of £11,386 for extensions of the generating plant at the electricity works, additional feeder and distribution cables, &c.

Wimbledon.—At the last meeting of the Council the new chairman of the Electric Lighting committee, Coun. Dudley Stuart, made an interesting statement on the position of the electric supply department.

He said he wanted it to be understood that the electric light undertaking was started purely for street lighting, at a time when the town was having some difficulty with the gas company. Since then they had not come on the rates for a single penny. Last year they made a gross profit equal to 9·14 per cent. on the capital outlay. If they put 4·57 per cent. (£7,653. 6s. 6d.) away for depreciation and to reserve, they would have still an equal amount to pay shareholders' dividend if they were a private company. The surplus, to the extent of £10,080, had been applied to reserve, which was equal to 5·07 per cent. on the capital. In addition, they had paid over £6,000 in relief of the rates.

Wireless Telegraphy.—It is announced that a wireless telegraph station is to be erected on the top of Pike's Peak, Denver, Colorado, U.S.A., to be employed as the midway transmitting and receiving point for wireless telegraph transmission from the Atlantic to the Pacific Coast.

Wireless Telephony.—The "Western Daily Press" (Bristol) on June 6 contained a lengthy report of some experiments which are being carried out at New Passage, near Bristol, by Mr. Grindle Matthews. It was at New Passage where Mr. Raymond Phillip's "wireless controlled airship," which has been on view at the London Hippodrome, was constructed. The object of the experiments

Digitized by Google

described in the Bristol journal is the development of the wireless telephone and the wireless operation of torpedos.

L.C.C. Electrical Staff Dinner.—The first annual dinner of the L.C.C. Tramways electrical staff (Greenwich North and South sub-stations) was held on June 1, Mr. John H. Rider, M.I.E.E., presiding, supported by Mr. J. Shepherd, Mr. E. L. Pope, Mr. T. L. Horn and Mr. Walker.

About 70 members of the staff were present. After the loyal toasts an excellent musical programme was carried out, the whole of the contributors being members of the staff.

The toast "Our Chairman" was proposed by Mr. C. S. WRIGHT, who referred to the excellent design of the electrical system under Mr. Rider's charge. The toast was drunk with musical honours.

The CHAIRMAN responded, and in the course of an interesting speech advised his hearers that the only way to attain success in the electrical profession was to keep plodding on steadily, and to seize every opportunity that presented itself. He impressed on the staff the necessity for debating electrical problems amongst themselves, and urged as many as could to join the Institution of Electrical Engineers, concluding by stating that the success of the L.C.C. tramways was due in a great measure to the efficient way in which the staff carried out their duties.

In proposing "The Committee," Mr. WALKER referred to the difficulty in arranging a function of that kind, owing to the majority of the staff being on shift work, and the large area covered by the system.

Mr. A. L. JOHNSON responded, and expressed gratification that so many were able to be present. The representatives of the committee present included Messrs. F. Scott, C. S. Wright, H. Storey, C. A. Butcher and A. L. Johnson (hon. sec.).

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Aberdeen.—The traffic receipts of the tramways department for the past year were £70,076, compared with £70,744 in 1908-9, and the total receipts were £71,116, a decrease of £563.

Bootle.—The accounts of the electricity department for the year ended March 31 show total revenue £19,194, including £10,839 from sale of current by meter, £5,837 for current supplied by contract and £2,476 for public lighting.

Total expenditure was £9,016. Out of the gross profit of £10,177, interest on mortgage debt (£2,620), instalment of principal moneys (£2,044), and sinking fund (£2,194) were paid, leaving a net profit of £3,365 (compared with £1,805 in previous year). £1,926 was transferred to reserve, and £1,440 applied in relief of local rates. 3,143,501 units were generated, 1,250,937 sold to private consumers by meter, and 1,213,355 by contract and 297,644 were supplied to the public lamps, of which there are 174 arcs and small lamps, equivalent to 680·8 c.p. The total maximum supply demanded was 1,269 kw. £112,633. 14s. 9d. has been borrowed, of which £34,036 has been repaid. Works costs were 0·58d. per unit sold (against 0·67d.) and total costs 0·78d. (0·89d.); interest required 0·23d. (0·24d.) and instalment of capital and sinking fund 0·37d. (as in previous year). Total 1·38d. (1.5d.)

Bradford.—The total revenue of the tramways department for the past year was £259,096, an increase of £15,462.

The total expenses were £170,699, an increase of £503, and after paying interest (£22,407), income tax (£2,250), rent of leased lines (£4,137), repayment of mortgage loans (£1,112), and sinking fund (£29,342), there was a net profit of £32,365, of which £20,000 is to be allocated to relief of rates and £12,365 to reserve and renewals account. The increase in the receipts was due to improved traffic (£14,208) and increase in parcels department (£819). Receipts per car-mile were 10·977d., against 10·456d. Passengers carried were 50,518,813, against 47,660,011. The increased receipts were mainly due to the institution of through running between Leeds and Bradford, the takings for through tickets being £5,454. The number of tickets issued free to blind passengers was 43,852. The total capital expenditure is £930,113.

Burnley.—The total capital expended on the municipal tramways at March 31 was £198,365, an increase of £5,269 on the year.

The traffic revenue was £65,295 and the total receipts £65,525. Deducting the working expenses (£41,570), the gross profit was £23,955. Interest and sinking fund came to £10,834, and after paying rents for leased lines, income tax, &c., placing £6,000 to reserve and £1,000 to contingencies, the balance (£3,232. 13s. 11d.) was transferred to the Borough Fund account. 12,911,113 passengers were carried, against 12,176,782; and 1,263,118 car-miles run, against 1,229,224. The average fare per passenger was 1·22d., against 1·20d., and the traffic receipts per car-mile were 12·22d., against 12·41d.

Canterbury.—The total revenue of the electricity department for the year ended March 31 was £9,370, including £8,840 net for electricity for public and private lighting and power.

Working expenses were £4,785 and gross profit £4,585. Interest on loans £1,564 and repayment of loans and sinking fund £2,415, and after paying one or two small items the net profit was £562, against £94. Total capital expended is £67,593, an increase on the year of £1,214. 796,358 units of electricity were generated; 309,802 were supplied for private lighting and 172,907 for power and 206,143 for public lamps (12 arcs and 655 incandescents). The total maximum supply demanded was 465 kw.

Colchester.—The net revenue from the sale of current for the year ended March 31 for private lighting and power was £10,990.

The receipts from public lighting were £959 and from traction £2,948, the total receipts being £15,146, against £14,302. The total costs were £8,410, against £8,153, and after deducting interest (£2,195) and sinking fund, &c. (£3,073), writing off £872 for mechanical stokers and prepayment installations, and applying £240 in purchase of arc lamps for hire, there was a net profit of £414, against a deficit of £21. 16s. 11d. Of the net profit, £214 has been placed to depreciation and the balance applied in relief of rates. The capital expended is £83,049, an increase of £2,815. The total costs were 1·47d. per unit, against 1·46d. 1,372,340 units were sold, against 1,344,177. The equivalent of 56,191 8 c.p. lamps is connected (against 51,595 8 c.p.), and the maximum load was 895 kw., compared with 881 kw.

Croydon.—For the year ended March 31 the total receipts of the electricity supply department were £64,982. 10s. 2d., including £56,200. 10s. 8d. from the sale of electricity for private lighting, power and traction, and £7,302 from public lighting.

Total expenditure was £31,549 and gross profit was £33,433. After paying interest (£10,681), sinking fund and instalment of loan repaid (£11,614), and income tax (£1,353), the balance profit was £10,466, against £9,443. Total capital expended is £348,341, an increase of £4,877. 7,961,395 units were generated; 621,008 were supplied to the public lamps and 3,600,941 to the tramways department, and 2,349,646 were sold to private consumers. There are 419 public arcs and 317 incandescents, and the total maximum supply demanded was 3,319 kw.

In the report of the borough electrical engineer (Mr. A. C. Cramb) it is stated that the use of the metal filament lamp has continued to exercise a marked effect on the output, and although the net increase in consumers compared with two years ago is 617, the electricity sold for lighting is only 18,000 units more. Reductions in prices have also affected the tariff. Although the output increased by 531,044 units, the increase in revenue was only £332. 2s. 7d. The cost of generation was £2,989 less, and the cost of coal decreased from £13,566 to £10,528. The load factor was 22·85 per cent., an increase of 1·93 per cent. There are 3,593 consumers, an increase of 338. During the year 253 arc lamps have been replaced by high candle power metal filament lamps with satisfactory results. There has been a satisfactory increase in the demand for power, the total horse-power in motors being now 1,070, and there have also been as number of inquiries for electric cooking and heating.

Eastbourne.—The accounts of the electric supply department for the year ended March 31 show total capital expenditure of £173,533 an increase of £2,546 during the year.

The total income was £25,144 (against £25,109), and included £21,121 from the sale of electricity for private lighting and power and £2,020 from public lighting. The working expenses were £11,282 (against £11,517), leaving a gross profit of £13,861, and after paying interest, sinking fund, &c. (£11,661), there was a net profit of £2,200 (against £1,938), which was added to the balance in hand from which £1,509 has been placed to reserve, leaving £6,147. The works costs were 1·36d. (against 1·40d.) per unit, and the total costs 1·92d. (against 1·98d). 1,640,200 units were generated and 1,249,718 units sold (960,120 for private lighting, 140,506 for power and 149,092 for public lighting). The load factor was 12·99 per cent. (against 13·13), and the maximum load was 1,098 kw., against 1,096 kw. The total connections to the mains (including 117 motors and 97 arc lamps) are equal to 111,755 30 watt lamps (against 105,719), and the consumers number 1,584, against 1,426. The units sold for private lighting decreased by 2·6 per cent. (against an increase of 0·3 per cent.), and the revenue from private lighting decreased by £165, but power showed an increase of £107. There are 117 motors of 311 H.P. (including 74 on hire) connected.

Glasgow.—During the year ended May 31 the tramways department carried 222,730,571 passengers, an increase of 986,002.

The average track (single) mileage open was 188¼ miles, an increase of 8 miles; traffic receipts per car-mile were 10·225d., decrease 0·037d. A number of extensions (2·8 miles) were opened for traffic since June 1.

Gloucester.—The total receipts of the light railways for the year ended March were £16,372, including £15,342 traffic revenue.

The operating expenses were £12,268, and the gross profit was £4,104. Interest required £4,833 and repayment of loans £2,217. 3,843,553 passengers were carried and 603,211 car-miles run. 597,739 units of electric current were consumed for traction and car lighting. The capital expended is £131,300. 19s. 4d.

Nottingham.—The accounts of the electricity department for the year ended March 31 were adopted by the Corporation on Monday.

The city electrical engineer (Mr. H. Talbot) reported that during the past year two additional steam dynamos were installed at St. Ann's station, thus completing the equipment of the first half of the station. The total horse-power installed at the three generating stations is 17,345 H.P. (Talbot-street station 8,925 H.P., St. Ann's 7,700 H.P. and Eastcroft destructor works 720 H.P.) There were 39 extensions of distributing mains, making the total length 58·91 miles, an increase of 1·69 miles. The number of applications for electricity was 3,801, compared with 3,608, an increase of 193; the equivalent of 17,709 additional 32 watt lamps were connected, making a total of 386,887. There has been a steady increase in the use of electricity for power, 84 motors aggregating 349 H.P.) having been connected during the year, bringing the total up to 1,040 motors and 4,169 H.P. The number of units sold was as follows, viz.:—For lighting 3,893,241, power 2,164,277, traction 5,412,217, total

Digitized by Google

11,469,735, an increase of 16,939 units, 52·48 per cent. of the units for private lighting were sold at the reduced rate of 1½d. per unit. The total works costs were 0·99d. per unit (the same as in 1909), and the total costs were 1·69d. (1·59d.) Although there were many additional users of electricity for lighting there had been a still further decrease in the number of units sold for that purpose, due to the increased use of metal filament lamps. In some cases consumers have made a saving of 50 per cent. in the cost of lighting (with an increased light), compared with the corresponding account when carbon filament lamps were used. The gross income was £92,459, and the expenditure £47,489, the gross profit being £44,969. The sale of current produced £89,607; and generation and distribution costs were £31,964 and £1,882 respectively. The total net income was £45,742. Interest on consolidated stock and loans, with contributions to sinking fund and instalment for repayment of loans (£13,204), &c., absorbed £28,957; and £16,700 is to be contributed to the general district rate, leaving £83. 9s. 10d. to be carried forward.

In moving the adoption of the report the chairman of the Electricity committee (Sir John Turney) said that the increase in the sale of current during the year had been the smallest since the undertaking was started. They regretted that the profits for the year was not larger, especially when they took into consideration the fact that they paid £1,800 less for coal. But for that good slice of luck, there would have been a big falling off. They had received an intimation from the Assessment committee that, although they were paying £6,000 out of their earnings in rates and taxes, the assessment was to be increased by £10,000, which meant that another £4,000 would have to be taken out of their earnings if the assessment was insisted upon.

Peterborough.—The accounts of the electricity department for the year ended March show a deficit on the year's working of £1,801, compared with a surplus of £89 in 1908-9

The deficit is mainly due to costs in the arbitration proceedings with the Tramway Co (£1,016), and as a result of the case £267 was refunded to the company. Though the Corporation are supplying current to more lamps than ever before, the consumption was less owing to the extended use of metal filament lamps.

St. Helens.—On the past year's working of the electricity undertaking the net profit was £1,031, of which £600 has been placed to plant renewal and accident fund and £431 carried to reserve fund. 2,779,464 units were sold, an increase of 12 per cent.

West Bromwich.—The capital expenditure on the electricity undertaking at March 31 was £75,118, an increase of £1,509 compared with 1909.

The income from the sale of current was £12,662. 17s. 3d., a decrease of £409. 1s. 10d. The total number of units sold was 2,010,608, a decrease of 1,377. The annual expenses were £6,902. 3s. 2d., against £6,740. 5s. 11d. The gross profit amounted to £6,348. 16s. 3d., against £6,855. 19s. 8d. Net profit was £1,756. 3s. 6d., decrease £686. 3s. 5d.

The net capital expended on the tramways is £134,786. The South Staffordshire Tramways (Lessee) Co. paid as rent of lines £8,606, less £502 for income. After providing for sinking fund, &c., and taking into account bank charges and sundry expenses, the net profit on the rental of the lines was £246.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.—The 1910 Edition of the Big Blue Book is NOW READY, price 15s., post free in the United Kingdom, 15s. 9d. The volume brings a great mass of very valuable statistical and technical data quite up to date, and the Directorial Division has been thoroughly revised and amplified up to February 16th.

All branches of Electrical Engineering and Industry are fully treated, and Electro-Financial matters receive every attention in the new volume, which aggregates more than 2,000 pages. The Directory Division is complete and thoroughly accurate, and has been completely revised. The Big Blue Book contains more names of live electrical firms and persons than any other Directory published, and this notwithstanding **that all mere lists of members of Societies and Institutions (so easily and cheaply available) are excluded, as unreliable and of little value for Manufacturers' and Dealers' purposes. The full set of valuable Statistical and Engineering Tables, &c., have been very carefully revised and extended, and are now issued in a handy form. These are included in the 1910 Big Blue Book, making it the most complete work of the kind ever published.**

TRADE NOTES AND NOTICES.

TENDERS INVITED.

BELFAST Harbour Commissioners are prepared to receive tenders for the construction, delivery and erection in their electric light station, Abercorn Basin, Belfast, of a direct-coupled steam engine and dynamo, with all requisite accessories. Specifications and form of tender, &c., from the harbour engineer, Mr. W. Redfern Kelly, M.Inst.C.E. Tenders to the secretary, Mr. W. A. Currie, Harbour Offices, Belfast, by June 22. See also an advertisement.

The Electricity committee of the County Borough of NEWPORT (Mon.) invite tenders for the supply and erection of l.t., h.t. and e.h.t. switchboards. Specifications, &c., from the borough electrical engineer and tramway managers, Mr. H. Collings Bishop, M.I.E.E. Tenders to the Town Clerk, Town Hall, Newport, Mon., by Monday, June 27. See also an advertisement.

Tenders are invited for supply of 36,000 incandescent electric lamps to the City of MELBOURNE. Specifications, forms of tender, &c., from the agents for the City Council (Messrs. McIlwraith, McEacharn & Co. Proprietary, Ltd.), Billiter-square Buildings, London, E.C., to whom tenders by noon July 1. See also an advertisement.

Tenders are invited by July 6 for the supply of cordless switchboards to the Postmaster-General's Department in SOUTH AUSTRALIA. Tender forms and specification may be obtained at the Commonwealth Offices, 72, Victoria-street, London, S.W. See also an advertisement.

The Electric Lighting committee of HULL Corporation invite tenders for supply and laying of electric mains, &c., required in connection with the extension of the electric lighting mains during the period ending March 31, 1911. Forms of tender and specification from the City treasurer, Mr. T. G. Milner, and tenders, addressed to the chairman of the committee, must be delivered at the Town Hall, Hull, by noon June 20.

WEST BROMWICH Electricity committee invite tenders for the supply, delivery and laying of paper-insulated lead-covered feeder and pilot cables. Specifications, forms of tender, &c., from the borough electrical engineer and manager, Mr. W. A. Jackson, Electricity Works, West Bromwich. Tenders to the chairman of the Electricity committee, Town Hall, West Bromwich, by noon June 20.

BARNES Urban District Council invite tenders for supply of 4,000 yds. of 0·25, 0·25, 1·25 sq. in. triple concentric cable, paper insulated, lead sheathed and jute served, suitable for a working pressure of 660 volts, manufactured in strict accordance with the British Engineering Standards committee's specifications. Tenders to the Clerk to the Council, High-street, Mortlake, by noon June 14.

ERITH Council want tenders by noon June 20 for supply of a Lancashire boiler, mechanical stokers, superheater and pipework; a 750 kw. three-phase turbo-alternator, with surface condenser, air and circulating pumps and pipework. Specification from the Electrical Engineer.

DEVONPORT Corporation want tenders by noon June 15 for 12 months' supply of d.c. meters, paper-insulated cables, rubber-covered wires and cut-outs, lubricating oils., &c. Forms of tender, &c., from Borough Electrical Engineer.

The Council of the University of BRISTOL want tenders by noon June 11 for electric lighting and other electrical work in connection with the new chemical and physiological buildings. Specifications, &c., from the Registrar.

LONDON County Council require tenders by 11 a.m. July 5 for supply of 250 electric tramcar bodies and 250 electrical equipments for conduit and overhead systems. Specifications, &c., from the Clerk.

RAWTENSTALL Corporation want tenders by July 1 for permanent way construction and supply of steel poles, overhead equipment, cables, conduits, &c., for a tramway. Specification from the Borough Engineer.

BATLEY Council require tenders by noon June 23 for supply of a battery of accumulators, an automatic reversible traction booster and a battery charging booster. Specifications from Borough Electrical Engineer.

STOCKPORT Electricity and Tramways committees require tenders by noon June 22 for supply of carbon brushes, overhead line material, tubing, ironmongery, oils, &c. Forms of tender from Borough Electrical Engineer.

TONBRIDGE Council want tenders by July 1 for supply of a Lancashire boiler, economiser extension and pipework. Specification from Mr. M. P. Plunkett, Electricity Works, Tonbridge.

Tenders are required by June 28 for supply of electric light and power plant and wiring at the County Asylum, Knowle, FAREHAM. Specification from the County Surveyor, The Castle, Winchester.

MANCHESTER Electricity committee want tenders by 10 a.m. June 22 for meters, service cables, motors and starters. Forms of tender from Mr. F. E. Hughes, Town Hall, Manchester.

Digitized by Google

Tenders are required by June 11 for wiring and fitting a new Police Court at BARGOED (Glam.) for electric lighting. Specifications from Council offices, Cardiff.

EALING Corporation require tenders by noon July 4 for supply and erection of surface condensing plant, &c., at the electricity works. Specification, &c., from Town Hall, Ealing.

WEST HAM Education committee require tenders by 6 p.m. June 20 for wiring three schools. Specifications, &c., from Mr. Wm. Jacques, 2, Fen-court, Fenchurch-street, London, E.C.

BRISTOL Sanitary and Improvement committee want tenders by 10 a.m. June 13 for supply and erection of electrical plant and fittings at the proposed refuse destructor, Eastville, Bristol. Specification, &c., from City Engineer.

Tenders are wanted by noon June 13 for the electric lighting of the new asylum buildings on the Purdysburn estate, BELFAST. Specifications from Messrs. Watt, Tulloch & Fitzimons, 77A, Victoria-street, Belfast.

SOUTH SHIELDS Corporation want tenders by 10 a.m. June 13 for 12 months' supply of stores to the tramway department. Specification, &c., from the Tramways Manager.

WALLASEY Council require tenders by noon June 14 for the supply and erection of a water cooling tower. Specifications from engineer and manager of electricity department, Liscard.

PORTSMOUTH Corporation want tenders by 10 a.m. June 22 for one or two years' supply of coal to the electricity department.

Tenders are invited up to July 19 for supply and delivery of 4,200 telephone sets (as per schedule No. 231) to the Postmaster-General's Department in VICTORIA. Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W.

The Deputy Postmaster-General, BRISBANE (Queensland), will receive tenders until noon June 22 for supply of 130 miles copper tinned wire and 25,000 insulators. Local representation is necessary. Specifications, &c., from 72, Victoria-street, London, S.W.

Tenders are also invited for supply of 941,000 arc lamp carbons to the city of MELBOURNE. Tender form, specification, &c., from the agents (Messrs. McIlwraith, McEacharn & Co. Propty., Ltd.), Billiter Square-buildings, London, E.C., to whom tenders by Friday, June 17.

Tenders are invited up to June 14 for supply of 100 party line common battery telephone wall sets, 10 party line common battery table sets, 100 switches, common battery, single extension and intercommunication, and 3,000 telephone protectors to the Postmaster-General's department in VICTORIA. Tender forms and specification at the Commonwealth office, 72, Victoria-street, London, S.W.

The Deputy Postmaster-General, BRISBANE (Queensland), will receive tenders until noon June 22 for supply of copper wire and accessories, covered wire, iron wire, insulators, ironwork and sal ammoniac and zinc for batteries. Local representation is necessary.

The Turkish Ministry of Commerce and Public Works want tenders by Oct. 28 (Nov. 10) for a concession for the construction and working of electric tramways in CONSTANTINOPLE and suburbs. A deposit of £13,500 (sterling) is required with each tender. Local representation is essential. Copy of specification (in French) may be seen at 73, Basinghall-street, London, E.C.

TENDERS RECEIVED AND ACCEPTED.

London County Council have received the following tenders :—

39 double-deck car-bodies, with roof covers :—

Hurst, Nelson & Co. (*accepted*)	£14,040 0
Metropolitan Amalgamated Rail. Car. & Wagon Co.	15,366 0
United Electric Car Co.	14,742 0
Brush Electrical Eng. Co.	14,469 0

39 sets of electrical equipments :—

British Westinghouse Co. (*accepted*)	£12,753 0
British Thomson-Houston Co.	13,045 10
Dick, Kerr & Co.	13,006 10

40 centre-bearing four-wheeled bolster trucks :—

Hurst, Nelson & Co. (*accepted*)	£4,930 0
Metropolitan Amalgamated Rail. Car. & Wagon Co.	5,040 0
United Electric Car Co.	4,880 0

The Highways committee of London County Council have also accepted the tender of the British Westinghouse Co. for the supply of 40 sets of magnetic track and wheel brake equipments for double-deck cars at £2,280.

The Metropolitan Water Board have accepted the tender of the Appleby Crane & Transporter Co. for the erection of a motor-generator (to be manufactured by the General Electric Co.) for coal transporter apparatus at £105 ; and that of the Rees Roturbo Co. for a centrifugal pump and electric motor for Ealing, £55. 10s.

Tunbridge Wells Council have accepted the following tenders :—

Underfeed Stoker Co., mechanical stoker, £199 ; Fuller Mfg. Co., motor, £28. 5s. 6d. ; W. E. Burnand & Co., transformer, £3. 10s. ; Ross, Hotchkiss & Co., circulator, £60 ; and J. Bennett Lawes & Co., lagging, £5.

Leyton Council have accepted the following tenders :—

Headland & Headland, fire alarm post and single wire connection, £30 ; Reason Mfg. Co., annual supply of electrolytic ordinary meters ; Mordey, Fricker & Co., annual supply of electrolytic slot meters.

Kilburn & Co. (Calcutta) have supplied about 137 "Russa" electric fans to the electrical department of the East Indian Railway.

Burn & Co. have orders for gearing, &c., required in connection with the conversion of the Malakand Fort (India) water supply pumps to electric driving.

Dublin Corporation have accepted the tender of Fletcher & Phillipson for electric wiring at Bolton-street technical schools at £1,273. 7s. 6d.

Belfast Tramways and Electricity committee have accepted the tenders of J. H. Holmes & Co. for a motor booster and switchgear, and Cowans, Ltd., for switchboard extensions.

The Isle of Wight Joint Isolation Hospital Board have accepted the tender of the local electric light company for wiring the new hospital at Fairlee, Newport, at £113. 12s.

Wrexham Council have accepted the tender of the British Economical Lamp Co. for supply and renewal of metal filament lamps at 7s. 6d. per pillar for the first year and 5s. after.

Burnley Corporation have accepted the tenders of the United Electric Car Co. for two tramcar bodies at £292. 5s. each, and of the British Thomson-Houston Co. for car electrical equipments at £264. 8s. 6d. each.

Colchester Corporation have accepted the tender of W. T. Henley's Telegraph Works Co. for cable at £37.

Sheffield Council has accepted the tender of their electric supply department (at £45) for a 10 H.P. motor and wiring at the baths.

Heckmondwike Council have accepted the tender of E. Deane & Beale for condensing plant at £2,418.

Wednesbury Council have accepted the tender of the British Westinghouse Co. for a 230 kw. dynamo and gas engine.

Burton Council have accepted the tender of the Brush Co. for a synchronous motor-generator at £257. 10s.

Eastbourne Council have accepted the tender of W. T. Henley's Co. (at £130) for cable.

Blackpool Council have accepted the tender of the British Thomson-Houston Co. for h.t. switchgear for the South Shore sub-station.

Commonwealth Tenders.—The Australian Postmaster-General's Department have accepted the following tenders :—

Victoria.—W. T. Henley's Telegraph Works Co., telephone cable ; British Insulated & Helsby Cables, copper wire ; India Rubber, Gutta Percha & Telegraph Works Co., zincs for gravity cells ; Hellesens Enke & V. Ludvigsen, Hellesens' dry cells ; J. Bartram & Son, micro-telephones, wall sets and table sets.

N.S.W.—British Insulated & Helsby Cables, copper wire ; R. Johnson, Clapham & Morris, g.i. wire ; T. Zwicker & Co., g.i. spindles ; Noyes Bros., stay rods ; Dalgety & Co., porcelain insulators.

W. Australia.—British Insulated & Helsby Cables, bronze and copper wire ; Dalgety & Co., porcelain insulators.

S. Australia.—British Insulated & Helsby Cables, phosphor bronze wire.

Tasmania.—British Insulated & Helsby Cables, wall telephone sets, telephone cable and copper wire ; India Rubber, Gutta Percha & Telegraph Works Co., shackle insulators ; Western Electric Co., telephone cable ; J. Bartram & Son, wall telephone sets ; Gibbs, Bright & Co., copper wire.

BUSINESS NOTICES

Messrs. Clark, Forde & Taylor, 4, Great Winchester-street, London, E.C., notify that they will take into partnership, as from July 1, Mr. Reuben Marchant Sayers, A.M.I.C.E. There will be no change in the style of the firm.

The partnership between W. H. Trentham, Jas. Saunders and John Saunders (carrying on business as Trentham & Saunders), consulting and civil engineers, 39, Victoria-street, London, S.W., has been dissolved so far as concerns Mr. Trentham. Messrs. Jas. and John Saunders continue at the same address as Saunders & Saunders.

The partnership between John Anthony Littlewood and Fred. H. Beaumont (trading as Littlewood, Beaumont & Co.), electrical and motor engineers, Thirstin Ironworks, Honley, near Huddersfield, has been dissolved. Debts by Mr. Beaumont.

Digitized by Google

Sale by Auction.—Messrs. Horne & Co., 35, Old Queen-street, Westminster, S.W., will sell by auction at the Royal Arsenal, Woolwich, on 23rd inst., at 11 a.m., some unserviceable and obsolete stores, including quantities of iron and steel, brass, gun metal, lead, zinc, &c., electric cable, steam engines, lathes, machine tools, telegraph instruments, electric lamps, dynamos, &c. The lots may be viewed at the Royal Arsenal, Woolwich, on the Monday, Tuesday and Wednesday previous to and on morning of sale. Catalogues at the War Office, Whitehall; the Ordnance Office, Tower; and the Ordnance Office, Royal Arsenal, Woolwich. See also an advertisement.

Patent Development.—The proprietor of patent No. 13,891/1907, for "Apparatus for treating liquids electrolytically," desires to enter into arrangements for exploiting and working the same in this country. Applications to Messrs. Haseltine, Lake & Co., 7 and 8, Southampton-buildings, Chancery-lane, London, W.C.

Electric Fans in Marylebone.—Mr. A. H. Seabrook, general manager of the Marylebone electricity department, has sent us a copy of a pamphlet dealing with the appropriate subject of electric fans. All the cogent reasons as to why electric fans should be used are given, and various ways in which they may be employed in business and in domestic use are also provided. Illustrations of standard, desk and ceiling fans are shown.

New Shaped Osram Candle Lamps.—We learn that the General Electric Co., after careful consideration and attention to the manufacture, have been able to produce a standard pattern 10 c.p. Osram candle shape lamp, suitable for working on 25, 33, 50 and 55 volts, in a globe measuring 26 mm. in diameter. The shoulder of the cap measures 23 mm. The lamp is, therefore, suitable for using in practically all designs of candle fittings. The size and shape of the lamps will be found particularly attractive, and being all of one size they are interchangeable. The price remains as before (3s. 3d. each). As the appearance of this lamp is now so much altered, we are showing an illustration of it.

Equipment of a Modern Elementary Electrical Laboratory.—A small booklet issued by Mr. R. W. Paul contains some criticisms and views on the equipment of an electrical laboratory suitable for first year students.

It is pointed out that too much of the apparatus used in such cases is obsolete and generally in bad order, so that the student becomes disheartened and his attention is diverted from the laws which he is studying to the repair of the apparatus which are to prove them for him. It is also contended that all the apparatus required can be made up from eight very simple components, and that these components should be all interchangeable, an advantage which by no means obtains at present. The apparatus required is a unipivot galvanometer, a volt range multiplier and current shunt, resistance box, rheostat, selector switch, tapper key and a single-pole switch.

The remainder of the booklet contains details and descriptions of these items of apparatus, while a list of the various experiments which can be carried through by their aid is also given. Whether all the statements made by Mr. Paul will be approved by teachers of technical students is, perhaps, open to doubt, but we understand that Profs. S. P. Thompson and T. Mather, as well as Dr. Drysdale and Dr. Sumpner, are in agreement with him.

CATALOGUES, &c.

Siemens Supplies List.—Messrs. Siemens Bros. Dynamo Works (Ltd.) have ready a price list of electrical supplies covering all the articles used by an electrical contractor in his business. All these goods can be obtained from Messrs. Siemens Supplies Department, 39, Upper Thames-street, London, E.C., and at their various branches at home and abroad. The principal features of the catalogue to which attention may be called are the reduced prices for Tantalum lamps and particulars regarding Zed cartridge fuses. The latter useful apparatus was described in a recent issue of the Industrial Supplement. Particulars may also be found of watertight switch boxes, wires and cables, as well as, of course, details of the well-known standard system which is now being extensively used in installation work by some of het leading contractors. A description of a cheap knife switch which is being made in large quantities at Messrs. Siemens' Stafford works and the latest forms of horn lightning arresters are also to be found.

Paraffin and Spirit Engines.—Messrs. Chas. Price & Son, Broadheath, Manchester, are issuing a pamphlet dealing with paraffin and spirit engines. Full specifications of the engines are given along with illustrations showing the working parts. These engines are now being constructed for use on inspection cars for marine work and for various other industrial purposes. An interesting engine is the 1-cylinder air-cooled engine, which has been supplied for Admiralty work. These iengines are also admirably adapted for use with electric lighting sets for country house work.

Moving Iron Electrical Instruments.—From Messrs. Crompton & Co. we have received a copy of a catalogue dealing with moving iron electrical instruments both for alternating and continuous current work. These are made in the usual round, sector and edgewise types, while a special modification is designed with a bottom flange for fixing on the top of controller pillars. Portable instruments working on the same system are also made.

Siemens Central Battery Instruments and Telephone Condensers.—Messrs. Siemens Bros. & Co. forward a pamphlet in which are described central battery telephones arranged to work with every type of central battery switchboard, the patterns being suitable for fixing on walls and sides of tables, as well as for standing on desks or tables. The hand micro-telephone supplied with most of the types is similar to the latest P.O. standard instrument. The condensers are of the rolled type, being built of tinfoil and specially prepared and impregnated paper. They are very compact, and are made in several sizes and shapes to suit general conditions and requirements of telephone and telegraphic work.

Gearing.—The Power Plant Co. has ready a pamphlet dealing with the use of their gears in colliery and mining work.

Rivets, Bolts and Nuts.—The Rivet, Bolt & Nut Co., of Glasgow, forward a very handsome book containing details of their manufactures. In addition to prices and illustrations, particulars are given of the approximate weights of bolts, nuts, rivets and bars. Details of the British standard tests, and hints on heating rivets can also be found, while the inclusion of stamped dimensions and other information make up a handy book of reference for everyday use.

Imports.—The following are official values of electrical machinery, material and apparatus imported into this country (*a*) during May, 1910, and (*b*) during the current year from Jan. 1 to May 31, with the increases or decreases compared with the corresponding periods of 1909:—

Electrical machinery (*a*) £51,493 (increase £14,198), (*b*) £233,082 (increase £41,859); telegraph and telephone cables (*a*) £8,358 (decrease £154), (*b*) £6,1279 (increase £20,409); telegraph and telephone apparatus (*a*) £15,882 (increase £1,288), (*b*) £74,678 (decrease £443); other electrical wires and cables, rubber insulated (*a*) £19,765 (increase £15,961), (*b*) £68,992 (increase £47,166); with other insulations (*a*) £3,943 (decrease £3,573), (*b*) £12,837 (decrease £32,540); carbons (*a*) £11,569 (increase £2,869), (*b*) £57,860 (increase £3,095); glow lamps (*a*) £54,856 (increase £31,293), (*b*) £227,810 (increase £42,576); arc lamps and electric searchlights (*a*) £148 (decrease £767); (*b*) £1,549 (decrease £6,996); parts of arc lamps and searchlights (other than carbons) £6,049 (decrease £75), (*b*) £30,248 (increase £8,002); primary and secondary batteries (*a*) £3,407 (increase £575), (*b*) £17,248 (decrease £3,865). Total of electrical goods and apparatus, other than machinery and telegraph and telephone wire (*a*) £131,814 (increase £46,345), (*b*) £592,532 (increase £74,563).

Exports.—The exports of electrical machinery, material, &c., (*a*) during May, 1910, and (*b*) during the current year from Jan. 1 to May 31, and the increases and decreases compared with the corresponding periods of 1909, are as follows:—

Electrical machinery (*a*) £106,215 (increase £566), (*b*) £568,713 (decrease £11,101); telegraph and telephone cables (*a*) £66,185 (increase £24,640), (*b*) £870,321 (increase £683,042); telegraph and telephone apparatus (*a*) £13,383 (decrease £15,569), (*b*) £65,863 (decrease £28,714); other electrical wires and cables, rubber insulated (*a*) £34,954 (increase £13,608), (*b*) £172,380 (increase £62,220); with other insulations (*a*) £34,378 (increase £9,506), (*b*) £113,509 (increase £8,714); carbons (*a*) £1,223 (increase £333), (*b*) £7,413 (increase £4,052); glow lamps (*a*) £9,688 (increase £2,620), (*b*) £51,495 (increase £21,896); arc lamps and searchlights (*a*) £844 (decrease £537), (*b*) £7,766 (decrease £679); parts of arc lamps and searchlights (other than carbons) (*a*) £1,031 (decrease £219), (*b*) £5,711 (decrease £1,833); primary and secondary batteries (*a*) £7,747 (decrease £53), (*b*) £41,317 (decrease £4,884). Total of electrical goods and apparatus, other than machinery and telegraph and telephone wire (*a*) £206,549 (increase £43,765), (*b*) £1,524,628 (increase £785,535.)

BANKRUPTCIES, LIQUIDATIONS, &c.

The estates of Wm. Chalmers, electrical engineer, 142, Bath-street, Glasgow, have been sequestrated. A meeting to elect trustee and commissioners will be held on July 10 at the Faculty Hall, St. George's-place, Glasgow.

A receiving order has been made against John P. L. Donlevy, consulting electrician, 123, Tulse-hill, London, S.W. First meeting of creditors at Bankruptcy-buildings, London, W.C., on June 16, and public examination on July 14.

A meeting of creditors of Thornton & Crebbin (Ltd.) will take place on June 13 at the Queen's Hotel, Leeds.

Digitized by Google

An application for the discharge of Alfd. Horswill Gibbings, engineer, 17, Gambier-terrace, Liverpool, will be heard on July 1 at the Court House, Victoria-street, Liverpool.

A dividend is to be paid to creditors of Joseph Platt and Richd. Bleasdale, electrical engineers, Victoria-square, Bolton, and also in respect of the separate estate of Richd. Bleasdale. Claims to Mr. H. Mather, 10, Acresfield, Bolton, by June 28.

The Electric Sterilizing, Carbonizing & Stripping Co. (Ltd.) is being wound up voluntarily. Mr. H. Appleyard, Prudential Buildings, Market-place, Dewsbury, is liquidator. Creditors will meet at his office on June 20.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

Note.—The undermentioned Applications (except those marked †) are not open to public inspection until after acceptance of Complete Specifications. Those marked † are open for inspection 12 months after the date attached to them, if they have not been published previously in the ordinary course. Names within parentheses are those of communicators of inventions. When complete Specification accompanies application, an asterisk is affixed.

March 26, 1910.

7,489 Crompton & Co., Macfarlane & Budgé. Dynamo-electric machines.

March 29, 1910.

7,573 Black. Single-phase alternate-current motor.
7,574 Macalister. Determining the position of faults in electric mains.
7,587 Goddard. Prepayment electricity meters.
7,589 Gorham. Resuscitating the negative plates of secondary batteries and assisting in their formation.
7,593 Smith. Charging electrical accumulators.
7,617 Pecszus. Electric igniter for explosion motors.*
7,621 Prentice. Electric train control system.*
7,641 Bloxam. (E. Hoorickx & A. Hindeb, Belgium. Current terminals for use in the manufacture of mirrors by electro-deposition. Addition to No. 2,493/09*
7,656 Egner & Holmstrom. Cooling devices for telephone transmitters for strong current. (Date applied for, 3/4/09.)*†
7,659 Neuhold. Automatic telephone systems. (Date applied for, 20/4/09.)*†

March 30, 1910.

7,714 Goulet. Hydrocarbon incandescent lamps. (Date applied for, 16/9/09.)*†

March 31, 1910.

7,808 Frost. Electric current generating and motive power machine.
7,821 Siemens Bros. Dynamo Works. (Siemens Schuckertwerke G.m.b.H., Germany.) Arc lamps.*
7,822 Siemens Bros. Dynamo Works. (Siemens Schuckertwerke G.m.b.H., Germany.) Starting of polyphase electric asynchronous motors.*
7,823 Conradi & Conradi. Electrical distribution boards and safety switch fuses and fuse carriers.
7,860 B.T.-H. Co. (G.E. Co., U.S.) Electric heating apparatus.*

April 1, 1910.

7,868 MacDonald. Electrical generators or motors.
7,892 Hopkins. Junction points for railways, tramways and the like.
7,929 Highfield. Electric fittings.

April 2, 1910.

7,963 Ross & Co. Electric lamp.
7,966 Sutton. Anti-vibratory devices for electric and other lamps or burners.
7,995 Woollard & Evans. Adjustable coupling for magnetos and other machines.
8,014 Buck. Electric lampholders.
8,018 Thompson. (George, Graf von Arco, Germany, and Ragnar Hakan Rendahl, Sweden.) Variometers for electrical oscillations.*
8,024 Graham. Telephonic transmitters.*
8,031 B.T.-H. Co. (G.E. Co., U.S.) Tungsten and the manufacture thereof.

April 4, 1910.

8,076 Zweigberck. Controllers for electric motors.
8,083 Lundberg, Lundberg & Lundberg. Electric switches.*
8,125 Heraeus G.m.b.H. Starting alternate-current mercury vapour lamps. (Date applied for, 17/1/10.)*†
8,126 Heraeus G.m.b.H. Shunt circuit-tilting devices for mercury vapour lamps. (Date applied for, 24/1/10.)*†

April 5 1910.

8,167 Nasmith. Enclosing the arc of arc lamps. (Tito Livio Carbone, Germany.) (Addition to No. 17,448/09.)*
8,219 Leitner. Reversible variable speed dynamos. (Date applied for, 31/7/09. Comprised in No. 17,847, dated 31/7/09.)
8,225 Adams Mfg. Co. (Cutler Hammer Mfg. Co., U.S.) Electromagnetic breakers and means for resetting the same from a distance, and in signalling devices combined therewith.*
8,226 Taylor. Switch for use on motor cars lighted by electric lamps.
8,228 Neuhold. Telephone exchanges. (Date applied for, 10/6/09.)*†

April 6, 1910.

8,257 Ayton. Electric sparking plugs.
8,274 Barry & Clarke. Rheostats.
8,286 Lehmann, Harvey & Inrig. Variable-speed dynamo for motor-car lighting.
8,288 Warmbold. Overhead electric cables.
8,294 Chalmers & Co. Magnetic clutch. (Date applied for, 6/4/09.)*†
8,332 Chisholm. Telephone system and individual transmitter.*
8,341 Cervenka. Incandescence filament or body and process for manufacturing same. (Date applied for, 23/10/09.)*†

SPECIFICATIONS PUBLISHED.

1909 Specifications.

7,576 Brookes. Couplings or connections for electric conductors or cables and the like.
7,593 Handcock, Dykes & Rawlings. Connecting or jointing of electrical conductors and means therefor.
7,995 Simplex Conduits, Ltd., & Waterhouse. Junction and the like boxes.
8,111 Sharman. Discharge gaps for the production of electric oscillations.
8,165 Spencer. Electrical distributing systems. (Request under sec. 19 not granted.)
8,382 Hanna & Hanna. Manufacture of bushes or bearings. (Cognate Application, 22,869/09.)
8,419 Gray. Electric conductors.
8,489 Burks. Magneto-electric machines. (Date applied for, 5/3/09.)
8,694 Thomson. Electric coal-cutting machines.
8,781 B.T.-H. Co. (G.E. Co., U.S.) Manufacture of rods or filaments of refractory material.
9,133 Mayor & Mayor & Coulson. Enclosed electrical machines. (Cognate application, 16,174/09.)
9,456 Hawker. Electric switches.
9,686 Sharman. Out-going telegraph signal recorders.
9,812 Mackay. Shade-holders for incandescent electric lamps.
10,586 Rymer-Jones. Wireless telegraphy.
10,729 Cochrane. Through control magnetic switches.
10,940 Marsh. Electric time switches.
11,060 Johnson. (Chemische Fabrik Griesheim-Elektron.) Production and maintenance of long electric arcs for effecting reaction between gases.
11,135 British Insulated & Helsby Cables, Cole & Shaw. Insulating of electric cables.
11,338 Spalazzi. Electrical device for transmitting angular movements to a distance. (Dated 13/5/09.)
11,400 Allgemeine Elektricitats Ges. Electric systems for power transmission. (Date applied for, 13/5/08. Addition to No. 11,339/09.)
11,634 Siemens Schuckertwerke Ges. Electric motor meters. (Date applied for, 6/6/08.)
11,773 Johnston. Ceiling roses, junction boxes, conduit boxes, and like electric fittings.
12,254 Bluhm. Third rails for electric traction systems.
12,878 Akt.-Ges. Kostin's Elektricitatswerke. Electric motor meters. (Date applied for, 9/11/08.)
13,142 Curtis, Mould & Adams Mfg. Co. Electric rheostats, motor-starters and the like.
13,612 Kemble. Insulators for supporting electrical conductors.
13,798 Allgemeine Elektricitats Ges. Electric systems for power transmission. (Date applied for, 12/6/08. Addition to No. 11,339/09.)
15,371 Houghton, Allman & Gray. Collector shoes or skates for electric traction systems. (Date applied for, 2/6/09.)
15,544 Thomas & Thomas. Electrically-controlled brakes for cranes.
15,792 B.T.-H. Co. & Samuelson. Packings for elastic fluid turbine shafts. (Addition to No. 24,936/08.)
15,880 Jaburg. Arc lamps. (Date applied for, 26/5/08, originally included in 7,471/09.)
15,891 Huth. Generators for wireless telegraphy and telephony with continuous oscillations.
16,095 Hill. Electromagnetic clutches.
16,642 Aitken & British Insulated & Helsby Cables. Telephone switchboards.
16,855 Ges. fur Elektrotechnische Industrie & Gyuris. Production of electric licht between the electrodes of arc lamps.
17,107 Romer. Intercommunication telephone instruments.
17,561 Baker. Electric fly switches.
17,620 Siemens Schuckertwerke Ges. Indicating differences of pressure. (Date applied for, 6/8/09.)
17,627 Kuzel. Electric incandescent lamp with metal filament loops. (Date applied for, 4/1/09. Request under sec. 19 not granted.)
17,742 Giglio. Rectifying alternating currents. (Date applied for, 29/4/09.)
17,932 Karolyi, Klupathy & Berger. Process and apparatus for wireless operation of switches and other apparatus at a distance by sound waves and other vibrations. (Rights under sec. 19, Patents, &c., Act, 1907, not granted.)
18,193 Newton. (Farbenfabriken vorm. F. Bayer & Co.) Insulation of metallic threads, wires and bands. (Date applied for, 13/5/09.)
18,228 Conradi & Conradi. Safety electric connector plug.
18,511 Holdsworth. Self-driving electric heat and fluid pressure motor.
19,024 Unterberg & Helmle. Distributor for high-tension sparking apparatus for multi-cylinder internal-combustion engines. (Date applied for, 19/8/08.)
19,368 Dane & Perks, Dane & Co. Proprietary. Drying of or abstraction of moisture from insulated electric cables.
19,914 Fuller. Electric batteries.
21,854 Gray. (Seabolt.) Electric lamp fittings.
22,596 Neuhold. Automatic telephone exchanges. (Date applied for, 7/4/09.)
22,897 Lundberg, Lundberg & Lundberg. Electric switches.
23,316 Green. Cathodes for Röntgen-ray tubes and like appartaus.
23,628 Rossi. Detector of electromagnetic waves.
23,821 Siemens Bros. & Co. & Riber. Clamping and supporting devices for electrica l condensers.

COMPANIES' MEETINGS AND REPORTS.

ANGLO PORTUGUESE TELEPHONE CO. (LTD.)—The directors' report for the year ended Dec. 31 last states that the gross revenue was £49,489. 18s. 2d., of which operating, management and general expenses absorbed £27,235. 3s. 9d., and royalties to the Portuguese Government £1,487. 3s. 4d., leaving gross profit £20,767. 11s. 1d. After providing for debenture interest (£2,302. 18s. 4d.), sinking fund (£1,297. 1s. 8d.), income tax (£596. 8s. 2d.), and appropriating £7,500 to reserve and £500 to exchange fluctuation account the amount available for disposal, including £4,820. 18s. 2d. brought forward is £13,392. 1s. 1d. An interim dividend of 3 per cent. (tax free) has already been paid, and the directors recommend a final dividend of 5 per cent., tax free (making 8 per cent. for the year), leaving £5,392. 1s. 1d. to be carried forward. With a view to ensuring the Company's service and plant being maintained in the highest state of efficiency, the directors arranged for an inspection of the system by Mr. Frank Gill, chief engineer of the National Telephone Co. Mr. Gill, accompanied by Mr. Kerr and Mr. Kingsbury, two directors, recently visited Portugal, and recommendations resulting from that visit are now being carried out. The directors express their appreciation of the value of the engineering experience thus placed at the disposal of the company.

BIRMINGHAM & MIDLAND TRAMWAYS (LTD.)—The total revenue for 1909 was £99,713. 11s. 2d., compared with £97,004. 9s. 1d. for 1908. Expenses were £48,710. 6s. 7d., compared with £45,639. 16s. 6d. After providing for expenses chargeable to revenue (including repairs, maintenance, sums payable to corporations, and placing £3,000 to renewals account) there remains £48,003. 4s. 7d., added to £92. 7s. 6d. brought forward, making £48,095. 12s. 1d. Deducting interest (£28,483. 11s. 11d.) the balance was £19,612. 0s. 2d. Debenture sinking fund required £3,550 and preference dividend £11,537. 18s., leaving £4,524. 2s. 2d., and the directors recommend a dividend on the preferred ordinary shares of 1¼ per cent. for the year (£4,375), leaving £149. 2s. 2d. to be carried forward. Gross receipts from the tramways were £46,477. 17s. 4d., compared with £45,826. 1s. 2d. Gross receipts from the lighting and power departments amounted to £19,795. 1s. 8d., an increase of £4,834. 1s. 6d. Dividends received from investments were £27,228, compared with

Digitized by Google

£33,551. Capital expenditure during the year was £8,544. 2s. 3d., of which £1,590. 9s. 1d. was spent on the tramway and £6,953. 13s. 2d. on the lighting undertaking. The purchase by Dudley Corporation of the tramways and light railways in Dudley was completed in November last, and the price (£10,631) paid by the Corporation. A lease of the lines has since been granted to the company for 30 years from Jan. 1, 1909. An arbitrator has been appointed to determine the price to be paid for five years commencing July 1 last to Dudley Corporation for electricity for working the tramways. The supply of electricity to consumers in Oldbury has made good progress. The number of units sold to the Shropshire Co. for distribution by that company during the year was 4,386,341. The Board of Trade has granted the order authorising the transfer of the Smethwick electric lighting order, 1898, to the Shropshire, Worcestershire & Staffordshire Electric Power Co.

BRUSH ELECTRICAL ENGINEERING CO. (LTD.)—At the meeting on Monday the chairman, Mr. E. Garcke, said the past year had been one of great anxiety to the directors and staff. The troubles of the company and of other similarly-situated manufacturing companies were largely due to excessive competition. The cost of obtaining orders was enormously increased by such competition, and so greatly intensified the competition among English firms. The advent of the metal filament lamp had reduced the necessity for power-house extensions and additions to plant. They had been particularly hit during the last few years by the fact that there had been very few expansions of railways, tramways or light railways in this country. All electrical manufacturing companies in this country were in a similar position. They had during the past two years made very substantial reductions in expenses. During the current half-year business had been to some extent better. The engineering shops were more full of orders at present than they had been for some time past. He could not speak in too high terms of praise of the services rendered by their officers.

COMPANIA INDUSTRIAL DE ELECTRICIDAD (BUENOS AYRES).—For the year 1909 the gross profit was $78,932 (gold) and $1,930 was brought forward. After placing certain sums to reserve, &c., a dividend of 6 per cent. was paid and $523 carried forward. The directors have taken part, on behalf of the company, in the formation of two electric companies in the interior.

KALGOORLIE ELECTRIC POWER & LIGHTING CORPN. (LTD.)—At the meeting last week Mr. Roger W. Wallace, K.C., said that one of the difficulties the company had to encounter was that Continental firms offered to put down small plants in the mines—not only electrical plants, but also at the present time they were putting down a great many suction gas plants. That was extremely unfortunate, because Kalgoorlie was not a good place in which to use gas engines, and those who did use them would find out eventually that they would lose money by not buying electricity direct from the company. That referred principally to the smaller companies, but in addition to that they were always being threatened by the larger mining companies that they would put down their own plants. They had been extremely fortunate in their manager, and under his management they had never had any breakdown except from the effect of lightning storms, and such things as could not be contemplated. They had entered into larger contracts, which necessitate putting down a new unit of plant. They had issued sufficient debentures to clear off their bankers' overdraft, and to pay for that new unit. The duty charged on new plant which could not be bought in Australia was exceptionally high, and made it rather difficult to incur the expenditure they would like to incur for additional plant, &c.

UNITED ELECTRIC TRAMWAYS OF MONTEVIDEO (LTD.) — The directors' report for the year ended March 31 last states that the gross receipts of the tramway system for the year to Oct. 31, 1909, were $1,190,310, an increase of $96,440 compared with 1907-8. Operating expenses were $694,588, against $701,009, the net receipts showing an increase of $102,861 (or £21,885). Passengers carried were 29,293,804, an increase of 3,392,365, and the car-miles run 6,282,240, against 6,036,669. The extension of the power house and the installation of new plant are almost completed. Further extensions to the main car shed and store shed and other improvements have been authorised. The amount received from La Sociedad Comercial de Montevideo in respect of dividend and interest was £106,197. After providing for administration expenses and charging £39,800 for debenture interest, the credit balance is £63,863. 2s. 2d. making, with £11,118. 3s. 2d. brought forward, £74,981. 5s. 4d. After setting aside £2,200 for debenture stock redemption fund, transferring £15,000 to renewals and contingency account and paying interim preference and ordinary dividends (£18,731. 4s. 2d.), the directors recommend the balance dividends, absorbing £27,202. 9s. (making 6 per cent. on both shares for the year), carrying forward £11,847. 12s. 2d.

NEW COMPANIES, STATUTORY RETURNS MORTGAGES AND CHARGES.

NEW COMPANIES.

NEW LIVERPOOL RUBBER CO. (LTD.) (103,933.)—Reg. May 31, capital £150,000 in £1 shares (52,000 5½ per cent. cumulative preference), to take over business carried on at Liverpool, and elsewhere, by the Liverpool Rubber Co. (Ltd.) (incorporated in 1894), and to carry on the business of manufacturers of and dealers in indiarubber and other gums, rubber goods, electricians, &c. First directors, F. H. Smith and P. A. Birley.

T. E. MORGAN & CO. (LTD.) (109,957.)—Reg. June 1, capital £100 in £1 shares, to carry on the business of electrical, mechanical, gas and general engineers, light, heat and power suppliers, founders, &c. Private company. First directors, T. E. Morgan and O. Huxley.

STATUTORY RETURN.

SOUTH METROPOLITAN ELECTRIC LIGHT & POWER CO. (LTD.)—In return dated March 14 capital is £500,000 in 250,000 ordinary, 100,000 second preference and 150,000 first preference shares of £1 each. 123,000 ordinary, 50,000 second preference and 142,968 first preference shares taken up. £1 per share called up on 120,500 ordinary, 50,000 second preference and 137,600 first preference. £308,100 paid. £7,868 considered as paid on 2,500 ordinary and 5,368 first preference. Mortgages and charges, £240,000.

MORTGAGES AND CHARGES.

CRYSELCO (LTD.)—Trust deed, dated May 6, to secure £7,500 first and £7,500 second debenture stock. Property charged, land, factory and other buildings at Kempston, and company's undertaking and property, including uncalled capital. Trustees, A. Baker and H. S. Deacon.

RADYR ELECTRIC CO. (LTD.)—Issue on May 14 of £300 debentures, part of a series of which particulars have already been filed.

COMPANY INCORPORATED OUTSIDE UNITED KINGDOM.

UNIVERSAL WIRELESS TELEGRAPH SUPPLY CO. (LTD.)—Particulars filed May 28. Capital stock $100,000 in $5 shares. Reg. in New York May 14: Directors, S. F. Cuthbertson, T. Stockdale (England), and D. C. Munson (New York). Principal office, Manhattan, New York City. British address, Avenue-chambers, 42, Bloomsbury-square, W.C., where S. F. Cuthbertson is authorised to accept service.

CITY NOTES.

MEMORANDA (June 9).—Bank rate 3 per cent. (June 9, 1910). Price of silver, 24½d. per oz. Consols 82—82¼ for money; 82⅛—82⅜ for account. **Consols Pay Day, July 1; Stock and Shares Continuation Days,** June 27 and July 12; **Ticket Days,** June 28 and July 13; **Pay Days,** June 10 and 29; **Mining Shares Carry Over Day,** June 24.

PRICES OF METALS (London).—*Copper*, cash, 56⅜; three months, 57⅛. *Lead*, English, 12⅝—13⅛; foreign, 12⅝—12¾. *Spelter*, 22½—22⅝. *Tin*, English, 148—149; foreign cash, 148½; three months, 150¼. *Iron*, Cleveland, cash, 49/4, three months, 50/3.

BRITISH THOMSON-HOUSTON CO. (LTD.)—A meeting of the debenture stockholders will be held at 83, Cannon-street, London, E.C., at noon on 15th inst., for approving the appointment of new trustees—Messrs. Cosmo Bevan and Lewis Kerrison Jarvis, bankers, 54, Lombard-street, E.C.

DIESEL ENGINE CO. (LTD.)—For the year ended March 31 the credit balance was £2,956, making, with £6,075 brought forward, £9,031. The directors recommend payment of the preference dividend and the placing of £5,000 to general reserve, carrying forward £3,093.

DOULTON & CO. (LTD.)—The accounts for the past year show a debit balance of £16,010.

GLOBE TELEGRAPH & TRUST CO. (LTD.)—The trustees recommend a final dividend of 5s. 9d. per share net on the ordinary shares, making 5¾ per cent. net on the ordinary shares for the year.

HAVANA ELECTRIC RAILWAY CO.—The gross receipts for 1909 were $2,488,647, increase $211,840. The surplus earnings available for dividends were $816,331. 3 per cent. has been declared on the common shares, leaving $292,420.

LONDON ELECTROBUS CO. (LTD.)—Mr. R. D. Yelverton desires to hear from debenture holders or shareholders of this undertaking. He complains that he is experiencing a difficulty in obtaining information concerning the present position of the company, or of the syndicate which is supposed to have been formed to take over its business.

NATIONAL ELECTRIC CONSTRUCTION CO. (LTD.)—The directors' report for the year ended Dec. 31 last states that, after providing for debenture interest, depreciation, &c., the credit balance of £9,661 brought down was reduced to £6,322.

SAO PAULO TRAMWAY LIGHT & POWER CO. (LTD.)—This company has declared a quarterly dividend of 2½ per cent.

STOCK EXCHANGE NOTICE.—The Stock Exchange committee have been asked to grant quotations to a further issue of 20,000 £5 (fully-paid) and 20,350 £5 (£2 paid) 5 per cent. cumulative preference shares of the *Calcutta Electric Supply Corpn. (Ltd.)*

TRACTION & POWER SECURITIES (LTD.)—For the year 1909 the credit balance was £24,848, which, added to £5,775 brought forward, made £30,623. The directors have transferred £25,000 to investment reserve account, leaving £5,623 to be carried forward.

WESTERN TELEGRAPH CO.—The directors have declared the third quarterly interim dividend of 3s. per share (tax free) for the year ending June 30, being at rate of 6 per cent. per annum. The transfer books will be closed from 17th to 23rd inst. inclusive, and the dividend will be payable on 24th inst.

NOTES.

Mr. Lackie's Address.

As was only natural, Mr. W. W. LACKIE, in his presidential address to the Incorporated Municipal Electrical Association, touched upon some of the "burning questions" of electricity supply. One of these was depreciation. Mr. LACKIE'S view is that depreciation should be met by a sinking fund properly calculated. Any loss in efficiency should be met by the depreciation fund if the ordinary maintenance out of revenue is not sufficient to provide for this; in other words, loss in efficiency should be a running charge, such as repairs and maintenance. Obsolescence, in Mr. LACKIE'S opinion, does not involve depreciation, but a prudent authority may see the advantage of setting aside a sum for providing more up-to-date plant as may seem desirable. Perhaps the only difficulty in a classification of this kind is to distinguish sharply between the different classes in every case.

IT is well known that American engineers make a point of supplying light rather than energy. Mr. LACKIE is inclined to support this policy, and he suggests that a new lamp might be given to the consumer for every 100 or 200 units used. Since satisfaction depends, partly at least, on the goodness of the illumination, there is certainly something to be said in favour of the idea. The British public, however, are essentially conservative, and for that reason it is doubtful if the change would be welcomed. It might, perhaps, be felt that the liberty of the subject was being molested. What, we wonder, would have been the attitude of the supply authority if this system had been in force when the metal filament lamp made its appearance, and to what extent would the consumer have benefited? The subject is, of course, closely connected with tariffs, on which Mr. LACKIE also made some remarks. He evidently thinks that flat rates may make progress, but they must be based on the maximum demand of each particular class. There is no doubt that a flat rate appeals to the consumer, who, as Mr. LACKIE remarks, is liable to remember the high-priced units at 3½d. for 730 hours per annum and to forget all the cheap units at ¾d. In such cases a flat rate of, say, 2½d. per unit might seem a much better bargain.

Reflectors for Street Lighting.

THE technical success, or otherwise, of street lighting, so far as electric lamps are concerned, is to no small extent connected with the distribution of the light; and whilst popular impressions will not entirely be disregarded, the increasing attention now being paid to the science of illumination is likely more and more to make itself felt when decisions have to be reached between the claims of electrity and gas for street lighting. That this should be the case is certainly the wish of electrical engineers, since questions of the minimum illumination provided and the effective distribution of light have in the past been frequently discounted, if not entirely disregarded, by committees in coming to a decision on the merits of different schemes for public lighting. The introduction of dioptric globes has undoubtedly placed the flame arc lamp in a stronger position by enabling the rays of light to be distributed more effectively over the area illuminated. Now that metal filament lamps are coming into very extensive use for street lighting and lamps of higher candle-power are being employed, the question of reflectors is likely to become increasingly important. This point is emphasised by a Paper (given in abstract elsewhere) in which Dr. CLAYTON SHARP describes a novel form of reflector.

Digitized by Google

THIS reflector has been designed primarily for the illumination of suburban streets and sparsely populated districts, where the lamps are necessarily spaced rather far apart, and where it is very important that the illumination should be effective at some distance from the sources of light. In this particular, gas lamps are very deficient, the illumination, as shown by a photometer, being very patchy. The facilities afforded by electric lamps for distributing the light by means of reflectors are likely to be more and more appreciated in the future, and the type of reflector introduced by Dr. SHARP for securing the most effective illumination is certainly worthy of careful consideration by illuminating engineers. By using the polished metal type of reflector the author claims that a gain of from 200 to 300 per cent. is obtained in the effect. Engineers, however, will probably have to experiment with these reflectors for some time to ascertain if the glare is a serious disadvantage. In this connection, it was mentioned in the discussion following the reading of the Paper that when a lamp is placed so high that its light reaches the eye at an angle from the horizontal of not less than about 26 degrees, tests showed the glare to be practically nil.

Metering Large Demands.

WHERE the price of electrical energy involves a charge based on the maximum demand of the consumer it is obvious that the method of determining the demand is of considerable importance to large power users. As overloads of short duration are not usually of great consequence to the supply authority, it is customary to use demand indicators having a considerable time lag—that is to say, the instruments do not attain their full reading unless the load is maintained for several minutes. The Commonwealth Edison Co., of Chicago, who are one of the largest suppliers of electrical power in the world, and who sell energy in bulk to several large traction undertakings, have, in the case of large consumers, for some time based their annual fixed charge per kilowatt (occasionally as low as £3) on the maximum demand as given by the greatest consumption of energy in any individual hour; an additional charge based on the number of units used (and ranging from about 0·2d. upwards) being also made. For ascertaining this demand it is necessary to read the energy meters registering the supply at intervals of one hour, such intervals having, of course, to be observed with great accuracy. Efforts have naturally been made to record the meter indications automatically, with the result that a printing attachment has now been developed. This attachment can be applied to most types of meters, and prints on a strip of paper the actual reading in kilowatt-hours at any desired intervals, say, five minutes, quarter of an hour, or longer periods. From these readings the consumption during the periods in question can be ascertained. In its latest form this attachment can be fixed on a separate panel and is electrically connected to the meter of which the indication is to be recorded. It is interesting to notice that by means of these readings it is easy for the supply authority to ascertain the period of the day at which the maximum demand of the consumer occurs; and this information will, undoubtedly, prove of considerable value in determining the price at which energy can be supplied.

Transatlantic Cable Negotiations.—Many rumours have appeared in the public press during the past week concerning the alleged outcome of negotiations between the Anglo-American Telegraph Co., London, and others. We are able to state that, so far as any result is concerned, there is no accuracy in any one of the statements made. Certain negotiations are in progress, but no result had, at the time of our going to press, been reached.

Electricity Meter Approved by the Board of Trade.—On June 8th the Board of Trade approved of the pattern and construction of the continuous-current meter, No. 50,015, deposited at the Board of Trade on Nov. 26, 1908, by the Aron Electricity Meter, Ltd., and known as the Aron D.C. Watt Hour Meter, Type W.M., provided that the meter be tested, fixed and used as described in the specification and instructions dated June 3, 1910, and numbered H.7493.

Electric Traction in Germany.—According to the "Railway Gazette," plans are being drawn up for the construction of a new high-speed electric railway in Berlin and environs, which, starting in the north of the city, will extend to the suburbs of Reinickendorf, Wittenau, Tegel, Waidmannslust, Hermsdorf and Frohnau. The local authorities concerned have declared themselves willing to give the necessary land free of charge for any portions of the railway built as a surface line, and also to contribute part of the capital expenditure. The question of an interest guarantee is also being discussed. The line is being promoted by the Bergmann Electrical Co., of Berlin, and will, if constructed, form a useful supplement to Berlin's traffic facilities.

The Royal Society—On Thursday June 9th H.M. the King received an address from the Royal Society, which was presented by a deputation consisting of Sir A. Geikie, president, Sir A. Noble, vice-president, Mr. A. B. Kempe, treasurer and vice-president, Sir Joseph Larmor and Prof. J. R. Bradford, secretaries, and Sir W. Crookes, foreign secretary, with Mr. R. Harrison, assistant secretary, bearing the mace.

In the address the following interesting passage occurs :—

We are proud to remember that no less than 47 years ago King Edward was graciously pleased to enter the Fellowship of the Royal Society, and later, on his Accession to the Throne, to become our Patron.

Your Majesty enters upon the duties of your high station with a wider personal knowledge of the Empire and its various peoples than was ever possessed by any previous Sovereign of this country. Your subjects have had many proofs that this extended knowledge has been accompanied by an active sympathy with every cause and movement that will promote their welfare and happiness. The interest which your Majesty has shown in the progress of discovery and invention assures us that these elements of national greatness will continue to receive your favour and protection.

His Majesty replied as follows :—

I thank you for the loyal address of condolence from the president, Council and Fellows of the Royal Society on the death of my beloved father. It is a consolation to feel that your Society, numbering amongst its Fellows the most distinguished men of science of this country, sympathises with me in my terrible bereavement.

Your words of appreciation of the character of the late King are very welcome to me. He always regarded with the deepest interest those scientific discoveries and those applications of discoveries already made, which have been of such supreme importance in the advancement of civilisation. I also have watched with close attention the work of your Society, and it is my sincere hope that its prosperity will continue, and that a Fellowship of the Royal Society will always be esteemed one of the highest honours which can be earned by devotion to the cause of science.

I desire to thank you most cordially for your congratulations on my Accession to the Throne, and to assure you of my sympathy and support in your beneficient efforts for the promotion of natural knowledge. I gladly accede to your request that I should inscribe my name as Patron in your charter book.

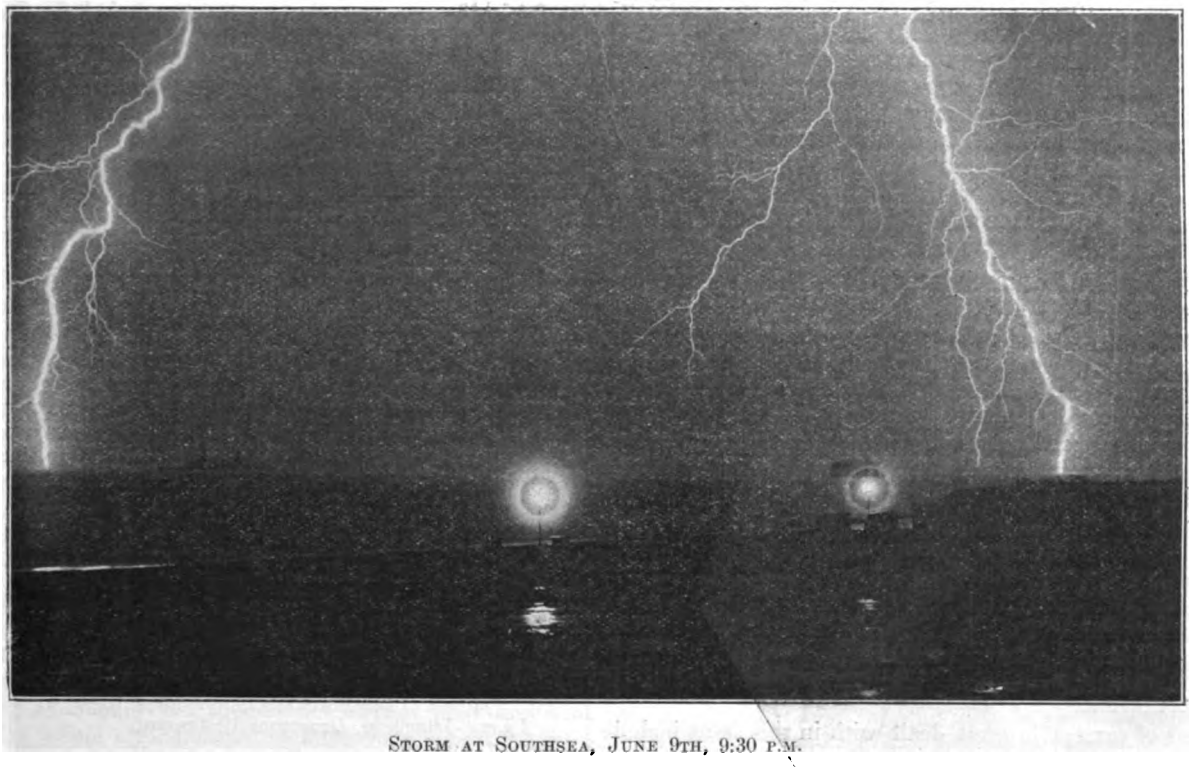
Tramway Development in Germany.—In an article in a recent issue of the "Elektrotechnische Zeitschrift" Mr. G. Dettmar gives statistical data of the position of electric tramways in Germany in 1908. The total length of the electric tramways is 2,575 miles, the total rating of the generators, 143,822 kw.; that of the storage batteries, 39,262 kw.; the number of cars, 20,249; the capital invested, £54,580,600. The average interest earned on the capital invested is 4·34 per cent. The values of interest in different parts of Germany vary greatly; the interest is lowest in the Province of Eastern Prussia, namely, 2·29 per cent., and highest in Hamburg, namely, 8 per cent. The average interest earned by tramways not operated electrically is 3·19 per cent. The total number of annual car-miles is 362,118,750, the total number of seats in the cars 622,635, the total number of passengers per year 2,103,119,000, the average number of passengers per kilometre 555,200, the average receipts per mile £2,800, the average cost of operation per mile £2,080, the average receipts per passenger 1½d., and the average cost of operation per passenger 1d.. About 82 per cent. of the German street railways are operated electrically.

Lightning Flashes.—The thunderstorms of unusual severity which were experienced in most parts of this country last week doubtless provided many opportunities to photographers for obtaining interesting records of lightning flashes. A striking example is reproduced herewith. This was taken at Southsea at 9:30 p.m. on Thursday, June 9th, by Mr. W. H. V. Marshall. The plate was exposed for five or six seconds, so that the lights on the ship (H.M.S. "Invincible"), on the Spit Fort and on the parade are clearly shown in the photograph. The two main lightning flashes in the field of view were practically simultaneous, and a very fine record of electric discharges has undoubtedly been secured. Attention may be called to the fact that the halos surrounding the arc lamps are due to the rain and could be seen with the naked eye, being similar to the familiar lunar halo.



Storm at Southsea, June 9th, 9:30 p.m.

Electric Heating and Pyrometry.—The Tyndall lectures at the Royal Institution have this year been delivered by Prof. J. A. Fleming, F.R.S., and where on the subject of electric heating and pyrometry. In the first lecture, on June 4th, Prof. Fleming considered electric furnaces based on resistance heating, describing their many applications, such as the production of carborundum, quartz glass, the reduction of aluminium from its ores, &c. After discussing induction furnaces and arc furnaces the lecturer passed on to electric heating apparatus, in which moderate temperatures are required. In this connection, "Silundum" heaters, the Bastian heater, the "Tricity" cooker, the Siemens heater and others were referred to; and the question of relative cost of electric and gas heating was then considered. To raise one pint of water from 60 deg. to boiling point requires about 56 watt-hours; for this work the "Prometheus" saucepan, Prof. Fleming stated, required about 60 watt-hours, a "Prometheus" kettle 65 watt-hours, and a large Isenthal immersion heater 66 watt-hours; whilst a gas ring with "Kwik" kettle used the equivalent of 89 watt-hours and a gas ring with ordinary kettle 99 watt-hours. Theoretically, the combustion of 1 cubic ft. of ordinary gas produced an amount of heat equivalent to 160 watt-hours; on this basis, with gas at 2s. 9d. per 1,000 cubic ft., the cost of heating a pint of water from 60°F. to 212°F. would be about ¼d. In practice, however, this figure was increased three times, making the cost about the same as with a good electric heater using electrical energy at 1d. per unit. To obtain the best results, the supply companies would favour some system of thermal storage, such as the "Therol" heater. In conclusion, the lecturer stated that until the price of current fell there was little prospect of an extensive adoption of electricity for domestic heating, but so far as cooking was concerned much depended upon the cost and durability of the apparatus. In the second lecture, on Saturday last, Prof. Fleming dealt with pyrometry. The two usual electrical methods of measuring temperature were by means of changes in electrical resistance and by the production of an E.M.F. at the junction of two metals. The various apparatus based on these two methods, viz., resistance thermometers and electric pyrometers, were described by the lecturer, who showed examples supplied by various firms. Amongst this apparatus was a direct reading thermo-couple pyrometer of Messrs. Crompton & Co., a quartz tube platinum thermometer of Messrs. Griffin & Son, the Féry radiation pyrometer of the Cambridge Scientific Instrument Co., and a platinum thermometer of Mr. R. W. Paul.

International Electro-Technical Commission.—We have received from the central office of this Commission a copy of the first annual report, which contains an account of the activities of the Commission up to December 31, 1909. The report is prefaced by a portrait of Col. R. E. Crompton, to-

Digitized by Google

whose efforts towards the formation of the Commission a tribute is paid in the preface, while in the same preface attention is called to the work which the general secretary, Mr. C. Le Maistre, is doing. This preface is signed by Prof. Elihu Thomson, who has been president of the Commission since 1908. The annual report proper begins by an account of the preliminary meeting held under the presidency of Mr. Alexander Siemens in June, 1906, and also briefly describes the formal election of officers and the first council meeting held in London in 1908. The report goes on to point out that at the present time there are 15 properly constituted committees, of which two, however, are not in full operation. Most of these committees are formed under the co-operation and assistance of the government of the country. With regard to the progress of the work during the year under review, there has been a large amount of correspondence dealing solely with the general work. Besides this, progress has been made in the purely technical work, especially in regard to nomenclature, the unit of candle-power, symbols and standards of electrical machinery. Summaries of the annual reports of the various committees are also given. We may say that the report is printed in two languages, English and French, the former language being confined to the left, and the latter to the right hand pages, so that it becomes truly international in character. We are asked to call attention to an invitation from the Belgian Electro-Technical Committee, stating that they are organising a reception to be held at Brussels from August 8 to 13, and will take this opportunity to bring together the various members of the committees at two or three unofficial meetings, so that they may exchange views, and in this way assist in the preparations for the official meeting which is to be held at Berlin in 1911. Members of the committee in this country are requested to inform the Belgian authorities as soon as possible of their intention to attend.

Operation of an Accumulator Lorry.—According to the "Electrical World" a 4,000 lb. electric lorry was run from Boston to Manchester, U.S.A., recently on a single charge, the distance being 59 miles. Throughout the trip a load of 2,500 lb. was carried. The lorry made an average speed of 8·57 miles per hour on the trip. Between Boston and Nashua the roads were in good condition, but on the last part of the journey, 19 miles, hilly and sandy highways were encountered. No boosting of the battery was resorted to on the way. The lorry is the seventh machine of its kind to be purchased by the Amoskeag Co., who are understood to be securing decided economies with electricity compared with the horse traction formerly used in their yards. The lorries are used mainly for inter-mill service, and a feature of the work is the constant overcoming of heavy grades.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

We give a complete account, up to last evening (Thursday), of the proceedings at the Convention of the Incorporated Municipal Electrical Association, held this week at Glasgow. The presidential address was delivered by Mr. W. W. Lackie, and the following Papers were read: "Commercial Advancement of Electric Supply," by Mr. A. C. Cramb; "The Commercial Progress of Electricity Undertakings," by Mr. H. Collings Bishop; "Exhaust Steam Turbines and Condensing Plant at McDonald-road Station," by Mr. F. A. Newington; and "Mixed Pressure Turbines," by Mr. A. Bremner. Discussions also took place on "The Advantages of Continuous Records of Costs and of Steam Consumption," opened by Mr. G. Wilkinson and Mr. C. E. C. Shawfield, and on "Cheapening of the Cost of Mains and Services," opened by Mr. S. E. Fedden and Mr. S. J. Watson.

Mr. R. M. Neilson contributes an article on "The Effect of Vacuum on the Economy of Steam Turbines."

Mr. F. Fernie continues his article on Electrolysis of Underground Mains.

At a recent meeting of the New York Section of the American Illuminating Engineering Society, Dr. Clayton H. Sharp read a Paper on "A High Efficiency Reflector for Street Lighting."

Messrs. Harper Bros. are reporting upon a proposal to erect a large power station in the Kroonstad mining district, near Klerksdorp, and for the transmission of electrical energy to Kimberley, Jagersfontein, Bloemfontein, &c., for mining, traction, power and lighting.

Several L.G. Board inquiries were held during the past week into applications for sanction to loans for electricity supply extensions, including Newport, for £31,255; St. Helens, £10,230; and St. Anne's-on-the-Sea, £3,000.

Legal.—Mr. Justice Neville commenced the hearing of an action on Monday brought by the Attorney-General (at the relation of a Leicester ratepayer) against Leicester Corporation to restrain them from undertaking wiring work, &c. Judgment was reserved.

Companies' Meetings, &c.—The directors' report of the British Electric Traction Co. for the year ended March 31 (abstracted on another page) contains particulars of the financial position of the tramway undertakings owned by the Company and its associated companies.

INSTITUTIONS AND SOCIETIES.

FARADAY SOCIETY.—At the meeting of the Society on May 31st the following nominations for the offices and Council (1910-11), to be elected at the annual general meeting on July 12th, were announced:—*President:* Mr. James Swinburne, F.R.S. *Vice-Presidents:* Messrs. A. C. Claudet, S. Z. de Ferranti (President I.E.E.), R. T. Glazebrook, F.R.S., F. W. Harbord, Lord Rayleigh, O.M., F.R.S., Ernest Solvay, Prof. James Walker, F.R.S. *Treasurer:* Dr. F. Mollwo Perkin. *Council:* Messrs. E. J. Bevan, Bertram Blount, W. R. Cooper, Dr. J. A. Harker, F.R.S., Prof. A. K. Huntington, Dr. T. Martin Lowry, Robert L. Mond, W. Murray Morrison, H. K. Picard, Dr. G. Senter.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.—Mr. Dugald C. Jackson has been elected as president of the Institute for the ensuing year.

INSTITUTION OF ELECTRICAL ENGINEERS.—On Monday, June 20th, the Institution offices will be transferred from Victoria-street to the new home on the Embankment. All communications after June 23rd should be addressed to the Institution at Victoria Embankment, London, W.C. The new telephone number is Gerrard 764. The library will be closed until Sept. 1st, for reclassification; and the common room will not be ready for use before the opening of the new session.

IRON AND STEEL INSTITUTE.—As previously announced, the autumn meeting of the Iron and Steel Institute will be held at Buxton, on Monday, Tuesday, Wednesday, Thursday and Friday, Sept. 26th to 30th. An influential reception committee has been formed, with the Duke of Devonshire as chairman, Sir Alfred S. Haslam as vice-chairman, and Major A. Brown as hon. sec. A good selection of Papers will be read and discussed, and visits to various works have been arranged.

ARRANGEMENTS FOR THE WEEK.

FRIDAY, June 17th (to-day).

INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION.

10 a.m. Annual General Meeting in the Rankine Hall of the Institute of Engineers and Shipbuilders, Glasgow.

1 p.m. Luncheon, Grosvenor Restaurant.

TUESDAY, June 21st.

FARADAY SOCIETY.

8 p.m. Meeting in the Rooms of the Chemical Society, Burlington House, Piccadilly, W. Papers on (1) "Studies in the Electro-metallurgy of Ferro-Alloys and Steel," by Mr. P. Girod. (2) "The Failure of the Light Engineering Alloys, particularly the Aluminium Alloys," by Mr. E. F. Law. Exhibit of some new types of mercury vapour lamps by Dr. F. Mollwo Perkin.

WEDNESDAY, June 22nd.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Meeting at Great George-street, Westminster. Lecture on "Recent Developments of Telegraphy and Telephony," by Sir John Gavey, C.B. James Forrest Lecture.

The Corps of Electrical Engineers (London Division).

Officer Commanding, Col. R. E. Crompton, C.B.

The following orders have been issued for the current week:—

Monday, June 20th, "A" Company.—Technical drill 7 to 9:30 p.m.; rating examination for those who have been warned.

Tuesday, June 21st, "B" Company.—Recruits infantry drill 6:30 to 7:30 p.m., technical drill 7:30 to 9:30 p.m. Any N.C.O. or man who has not yet performed his qualifying drills is reminded that they should be performed before Camp.

Wednesday, June 22nd.—Gymnasium 6:30 to 9:30 p.m.

Thursday, June 23rd, "C" Company.—Examination for ratings for all N.C.O.s and men who have been warned.

Friday, June 24th, "D" Company.—Examination for ratings for all N.C.O.s and men who have been warned.

ELECTRIC CABLES.*

ELECTROLYSIS.

BY F. FERNIE.

(*Continued from p. 283.*)

Summary.—The author first considers the general phenomena of electrolysis as observed in the neighbourhood of electrical networks. He then discusses in more detail the corrosion of lead-covered cables and armoured cables, and the effectiveness of earthing. Another cause of deterioration is electric osmose, which causes an accumulation of moisture at the negative conductor if there is any flow of current through the insulation. Finally, the causes of faults and measures for preventing them are considered. Faults may be classified into those of manufacture, those caused during laying, and those developed after the cables are laid. The last class is due to a number of causes, such as mechanical injuries, electrolysis and electric osmose, chemical action, overloading and decentralisation, high temperature, abnormal pressures and static discharges. Another cause of trouble is the accumulation of gas in manholes, causing explosions. The various ways in which gas may accumulate are considered and the remedies to be applied.

Causes of Faults; Measures for Preventing Them.

Speaking generally, cables used for alternating currents do not develop nearly so many faults as those used for continuous currents, and this in spite of the much higher pressures employed. Also, on a three-wire system, with earthed neutral, the negative cables break down sooner and to a greater extent than the positive cables. Moisture is to be avoided as much as possible, particularly on an earthed system and with leadless cables, and experience shows that it is much better for cables to be entirely submerged rather than merely wet. This is perhaps because the minute traces of chemicals that get deposited on the outside of the cable (as we think through electrolysis) rapidly diffuse away if there is any quantity of water present. Earthenware pipes, concrete, or brickwork tend to prevent diffusion, and thus cause an accumulation of salts on the surface of the cable. If it were practical, we believe it would be a good thing occasionally to flush out ducts containing leadless cables with clean water. Thus, in testing samples of vulcanised bitumen cables, with the insulation intentionally pared down to hasten the action, we have found the insulation to stand for long periods with 460 volts if the sample be immersed in a large volume of a neutral salt solution; but if it be put in a porous pot and packed in tightly with soil it will break down in a comparatively short time in the same solution.

Wishing to test samples of pitch and bitumen for use on a "solid" system, we installed bare conductors in stoneware troughs and filled in the troughing with the different samples, and connected the conductor to the negative pole of a three-wire system. In order to make the test as severe as possible, we wrapped another bare wire tightly round the outside of the troughing and connected this to the neutral pole, and then buried the whole arrangement. Under these conditions none of the samples would break down, we think because the soil was altogether short-circuited; by earthing the neutral a few feet away from the troughing we were able to break down some of the samples.

Leadless cables, particularly when in iron pipes, often break down close to the edge of the pipe. This is perhaps due to the fact that the protective action of the iron pipe, which is to make the path of any leakage current partly metallic, is impaired, and a current may flow through the insulation along wet tapes or braiding to the earth, its path being electrolytic. Similarly, cables are sometimes found to be faulty at definite equal distances spaced along the cable, these distances corresponding to the joints in the earthenware pipes, which if of cement provide a better earth for the cable than the body of the pipe. Negative faults always collect an akaline liquid round them, and it should be the custom of the mains foreman to test any trickle of water running down a duct into a draw box with pole-finding paper for alkalinity, its presence always indicating a faulty negative cable in the duct.

Faults on the positive and neutral wire (which is nearly always *above* earth potential) are generally acid, much drier and with the conductor corroded. The great object of the designer of joint boxes and other fittings for underground use is to exclude moisture, and faults caused by the ingress of water into joints, &c., should be regarded as due to faulty workmanship or material, and not as primarily due to water. No kind of fibrous substance, however well impregnated, can be regarded as waterproof.

There is one kind of fault the cause of which is difficult to classify; where bitumen cables are bent at all sharply the insulation will crack and open in time. Now service cables often have a nearly right-angled bend in them, and we have known many bitumen service cables to fail at this point.

Faults on underground mains may be roughly divided into three classes:—

1. Faults of manufacture.
2. Faults caused during laying.
3. Faults caused after the cables are laid.

A fault may be either an "earth," a "short-circuit" or a discontinuity. With single cables it is almost impossible to get a short-circuit unaccompanied by an "earth," and with concentric or multi-core cables it is also very rare. Positive and neutral leadless cables are sometimes corroded asunder by electrolytic action, and may be clear of "earth," but this has always been caused by an "earth" originally. Multicore pilot cables sometimes develop a discontinuity without an earth, this being generally caused by a short-circuit which has cleared itself.

The faults coming under the first class are exceedingly rare, probably less than 0·1 per cent. of all those occurring on a low-tension network. Cables used for extra high-tension currents may possibly give a larger percentage. Proper testing of the cables will eliminate practically all danger due to manufacturing defects.

Perhaps 30 per cent. of all faults might be included in class 2, their chief cause being rough and careless handling of the cables. Negligent workmen will get sharp bends and kinks in a cable, will stretch the lead, drag the cable over sharp edges and rough surfaces, and in other ways lay up a store of future trouble. Badly aligned and inherently bad ducts and troughs, badly designed joint boxes and carelessly made joints are also responsible for faults caused whilst the cables are being laid. In very cold weather special care has to be taken in all the operations of handling and laying cables. The general remedy for this class of fault is, of course, efficient supervision. Really reliable foremen and gangers are difficult to get, and should be treasured when found. Faults of the second class may not, and generally do not, develop for some months, or possibly years after the cable is laid, and when they do manifest themselves the defect from which they originated is difficult to recognise. Thus the foreman responsible for laying the cable escapes all blame, and it is on account of the absence of any immediate result from improperly handling cables that it is so difficult to impress him with the necessity of using them tenderly.

Faults in class three may be caused by

(*a*) Mechanical injuries.
(*b*) Electrolysis and electric osmose.
(*c*) Chemical action.
(*d*) Overloading and decentralisation.
(*e*) Excess of temperature.
(*f*) Abnormal pressures, surges, lightning.
(*g*) Static discharges.

(*a*) Faults in this category are most generally caused by workmen engaged in excavating the streets, for underground works, electrical or otherwise. Occasionally an iron spike used for supporting a barricade round some operation will be driven into buried cables. A particularly crude method used by gas engineers for finding leaks is responsible for some severe faults. This consists in driving a heavy steel bar a foot or two into the road bed on the supposed line of the gas main, and then applying the usual tests for the presence of gas. Unfor-

Digitized by Google

tunately, the point of the bar may unwittingly perforate an electric cable.

Cables laid under concrete (as installed for wood setts) are very liable to injury if the concrete has ever to be broken up for installing other works, because wedges and steel bars are driven through it at random. Subsidence of the ground which is particularly common with cables laid in mines and mining districts, comes under this heading. This may cause joints to be pulled asunder or severance of the cable. In one instance, where cables were laid solid in troughing, the ground fell away from the troughs and carried them with it, leaving the cable taut, with the protecting bricks and a considerable weight of earth above it, which in the end cut through the insulation. The laying of ducts or troughs may also indirectly cause subsidence owing to their acting as drains for water.

Attacks by rodents also come into this class. We have found nests of young rats in manholes, but recorded instances of damage from this cause are very rare. An inspector, under the direction of the mains department and provided with a copy of all permits given for street openings of any kind, will largely obviate faults due to mechanical injuries.

(*b*) *Electrolysis and Electric Osmose.*

Electrolytic damage is often underrated. It is discussed in relation to lead-covered cables in another part of this book. Although the term is generally applied to lead-covered cables, the slow deterioration of leadless cables possibly also is a kindred effect. Electric osmose is also discussed elsewhere.

(*c*) *Chemical Action.*

This is a relatively infrequent cause of trouble. Vulcanised bitumen is rapidly attacked by free alkalies, as discussed elsewhere. Coal gas in the soil attacks and softens bitumen, and we have seen the bitumen filling of "solid" laid cables attacked in this way. Callender-Weber bituminous casings are sometimes corroded in a similar manner with holes eaten right through the wall of the casing. The slow deterioration of rubber in dry places, and its more rapid destruction by condensed water, may be included under this heading, although vulcanised rubber with no electrical pressure on it, retains its elasticity better in a damp box underground than in a dry one.

Lead is not attacked by absolutely pure water, but oxygen dissolved in water causes lead to be corroded, forming a film of lead oxide (or dioxide) on its surface, which absorbs Co_2 from the air and forms an insoluble carbonate of lead. This permits more lead oxide to come into solution, and the process is thus cumulative. Nitrates, nitrites, chlorides and ammonia all increase the corrosion of lead, but hard water containing calcium and magnesium carbonates almost entirely prevents any corrosion. Lead buried in chalk remains particularly bright and clean.

The above kind of corrosion is, of course, generally very slow and as a rule negligible, but we have seen instances where there was a good deal of condensation on bare lead-covered cables suspended in the air, with probably a lot of Co_2 present, in which the lead was thickly coated with a white salt (carbonate) in a few weeks. Ducts should be kept dry, and in particular free from sewage contamination; and lead should be carefully protected in the neighbourhood of stables, farmyards and urinals. Stable manure and artificial garden fertilisers are liable to corrode lead, and this is a point to notice when laying in service cables through gardens. Important information as to durability may often be had from the experience with lead water pipes. PbO is a powerful base, and will combine with the weakest acids; lead in a finely divided state is extremely sensitive towards oxygen. Red lead in contact with lead in a moist place seems to cause rapid corrosion. It is probably the presence of organic acids in some pit waters that causes them to corrode lead. If in contact with wet wood (oak in particular) lead is sometimes badly attacked, due to the presence of some organic acid (acetic or tannic) produced from its decomposition. This is again a cumulative process and results in the formation of lead carbonate, a very little acid being used over and over again. The action is in some degree similar to the Dutch method of preparing white lead. It is fairly rapid, and we have seen lead sheathings corroded three parts through in a year or so. It is possible that the braiding used on lead-covered cables may itself rot in course of time if continually wet, and produce organic acids similar to those from wood. We have seen bad cases of cone-shaped pitting on cables used for alternating currents which may have been caused in this way. With reference to this speces of corrosive action, a mere film of moisture produces more marked effects than a large volume of water.

Wooden saddles impregnated with wood creosote, used for "solid" laid cables, have caused corrosion of the lead, and trouble was at one time experienced with telephone cables due to the use of creosoted wood conduits. Where conduits of this type are still used, oil of coal tar is better for impregnation than wood creosote, as it contains no acetic acid. With telephone cables, lead sheaths containing 3 per cent. of tin were found to be far less corroded than those of pure lead.

The salt glaze on earthenware casings is sometimes stated to have a chemical action on lead, but this lacks confirmation, and is very improbable. Cement and plasters are also often stated to attack lead, but this corrosion is in nearly every case due to electrolysis. Ashes badly corrode the steel armouring of cables, but do not appear to attack the lead, at any rate until all the armouring has disappeared. Care should be taken that ashes are not filled in round buried cables, and to safeguard them it is best to use troughing in "made up" ground.

(*d*) *Overloading and Decentralisation.*

This source of faults is most frequent with vulcanised bitumen and allied cables. Lead-covered paper cables of sections up to 0·5 sq. in. may be run at a current-density of 1,200 amperes per square inch for long periods without danger. Vulcanised bitumen cables, of course, vary considerably in kind, but probably 800 amperes per square inch is the maximum safe current-density for this size. Smaller sections may be run at a relatively higher current-density, for whilst the heat generated in a 0·2 sq. in. cable is twice that in a 0·1 sq. in. cable for similar current densities, the heat dissipating surface of the former is less than 1·5 times that of the latter.

Rubber insulation deteriorates more rapidly when heated up by overloads than when carrying normal currents. Vulcanised bitumen softens when heated, and the conductor tends to become decentralised. This statement is often made and nearly as often contradicted. We believe the effect takes place far more readily with some makes than with others, and not to so great an extent with the more modern cables as with the earlier ones. Some examples of decentralisation have been discussed earlier, and also the general question of the heating of underground cables.

(*e*) *Effect of Temperature.*

This is an infrequent cause of faults. Cables laid and jointed in warm weather may contract and break their joints during cold weather. This is, of course, very unlikely to happen when they are in constant use, owing to the heat produced in them by the load current. At week-ends, however, they may be so free from load that they will assume the temperature of the soil, and if this is low they may suffer severe strain, thereby causing distortion of the box fittings and bringing them into contact with earthed boxes and bonds. Some cases have been recorded of long feeders failing in this way. That there is a considerable strain may be seen by cutting a heavy feeder cable in cold weather, when the two cut ends will sometimes spring apart as far as 18 in. On the other hand, cables laid "solid" in cold weather must expand a little when they are used, and, being held everywhere rigid, must tend to break some of the joints of the troughing in which they are laid; this effect is, however, insignificant, the expansion of a cable 1 mile long being about 1 in. per degree centigrade. Rubber and bitumen cables rapidly deteriorate when laid in proximity to baker's ovens, and they should be avoided as much as possible when laying cables, although this is sometimes difficult.

(*f*) *Abnormal Pressures.*

Pressure rises may be caused in many different ways: by any disturbance on the circuit, abrupt change of load or poten-

Digitized by Google

tial, by resonance, or by lightning phenomena. A lead-covered paper-insulated cable is hardly ever broken down by high-pressure rises occurring in practice, the failure generally taking place at joints or other fittings, transformers, &c. A momentary concentration of potential often takes place on the end turns of transformer or motor windings when switched into circuit. Even on 2,000 volt circuits we have found that when transformers fail it is nearly always due to a short-circuit on the high-tension winding, and not a breakdown to earth. At least one British firm put extra insulation on the end turns of all their transformers. On high-tension circuits, and particularly where the line is overhead and subject to lightning disturbances, a choking coil is often connected in the line to act as a buffer to receive the shock of any wave of potential.

Some oscillographs illustrating the rise in pressure produced when switching on a cable, obtained by Mr. Duddell from the County of London Supply Co.'s system, are shown in the *Proc.* of the I.E.E.* When switching on 9 miles of rubber cable on open circuit at 2,000 volts, using brass contacts in air, a rise of 2·25 times the root mean square value of the generator volts was obtained. Switching on the cable with loaded transformers is said by Mr. Duddell to reduce the pressure rise, but with a 400 kw. transformer on *open* circuit, connected at the far end of the cable, a rise in pressure of 2·7 times the root mean square generator volts was obtained under the same conditions as above. It is improbable that very quick rises of pressure, maintained for very short periods such as the above, will do any damage, but they may be prevented by charging up a cable through a resistance, or by putting the machine on at a low pressure and raising it gradually by means of the exciting current.

A rise in pressure when switching off an inductive circuit may be prevented if the current is alternating by breaking the circuit under oil, which has the effect of breaking the current at or near the instant when it reverses. The rise in pressure on breaking a current depends on the rate of change of current di/dt; hence continuous currents should not be broken under oil, but to reduce the pressure rise the arc should be drawn out as long as possible. A condenser connected across a switch or fuse will tend to break the arc immediately, because the condenser behaves (until charged) as a momentary short-circuit to the arc; lead-covered cables, intercepted by a fuse, may act as condensers in this way. On some of the long transmission lines in America it is found to be easier to work with high voltages than with relatively lower pressures, because the current being less with the higher pressures the effect of breaking it is not so disastrous. On these long lines, short-circuits or other disturbances may set up violent oscillations or surges in the line.

Resonance effects are unlikely to occur with commercial frequencies (25 or 50 periods) except on very long lines or with a large number of feeders supplied in parallel; the frequency of any oscillation set up in the circuit depends inversely on the square root of the product of capacity and inductance, and thus the larger this product is the lower will be the applied frequency which will produce resonance. Mr. Sayers† quotes an instance of resonance troubles occurring on 100 miles of high-tension mains. The cables used to fail in a wholesale way, always during the hours of light load, when the frequency of supply was reduced to about 65, the normal frequency being 83. Mr. Sayers found by calculation that resonance was probable at frequencies from 60-65. He raised the light load frequency to above 70 and the wholesale cable failures ceased. Mr. Patchell has also given the results of some interesting calculations on this point in connection with the Charing Cross Company's Bow (London) works.‡

Lightning phenomena are not often manifested on wholly underground systems, but are often a great source of trouble on these when associated with overhead systems. We have, however, seen several case of lightning charging underground mains. Cables used for a town supply come to the surface in a consumer's premises, and the whole system may get charged if a building is directly struck by lightning, but it is more probable that an electrostatic charge is induced by a heavily charged cloud immediately above. A conductor inside a conducting vessel is screened from all electrostatic influences, hence lead-covered or armoured cables, or any class buried fairly deeply in good conducting soil, are completely screened from induction by a cloud, but it would appear possible that non-lead-covered cables laid in insulating ducts above cellars with very little covering but the dry pavement flagstones, and also bare copper strip strained in culverts, also with very little covering, and that nearly insulating, might be electrostatically charged. The subject is of great interest, but its occurrence too rare to discuss fully here.*

(*g*) *Static Discharges.*

Rubber cables have been known to fail when carrying high pressures when they are near some earthed metal. This is attributed to a kind of brush discharge which oxidises the rubber and destroys its insulating properties in course of time.

Practically all the causes mentioned above as the origin of faults must operate equally on all the three cables of a three-wire system, yet with leadless cables the negative cables develop at least 90 per cent. of all the faults; with lead-covered cables the proportion is more equal between the positive and negative mains, and this is probably because the electric osmotic effect is largely eliminated.

Third wire faults are very rare if the third wire is always kept anchored down at earth potential; they chiefly develop in the immediate neighbourhood of positive or negative faults. The following table is due to Mr. C. E. Phelps, and gives the number of faults from all causes on the high and low tension and telephone cables in Baltimore during the seven years ending December, 1906, the total length of cable in operation being about 290 miles.

Nature of damage.		No. of faults.		Percentage of whole.
Defective cable		3	.....	2·0
Damage during installation		24	.....	16·0
Mechanical injuries	Damage by picks, bars, &c.	58	.....	55·0
	Floods	2	.....	
	Gas explosions	2	.....	
	Rats	5	.....	
	Workman in manholes	13	.....	
Electrolytic action		31	.....	20·0
Cables above ground		2	.....	1·5
Unknown		8	.....	5·5

This table exhibits generally the number of faults to be expected in a modern city from external and mechanical causes. It is no criterion of the number and importance of faults that are consequent on electrical defects, such as electric osmosis on three-wire systems. Half the mechanical faults occurred during two years when many street improvements were carried out after a fire, so that the percentage shown in the above table s not an exact guide for ordinary practice.

(*To be concluded.*)

Telephony from Ship to Shore.—According to the "Electrical Review and Western Electrician" the steamer "Theodore Roosevelt," which is to take the members of the Chicago Association of Commerce on a tour round the cities of the Great Lakes in June, will be in direct telephonic communication with Chicago during its entire trip. While at sea, wireless telegraphy will enable them to send and receive messages, and the Chicago Telephone Co. will install a portable telephone outfit for use on the boat. The Company has arranged with the telephone companies of the various cities to be visited by the Chicago delegation to have wires laid to the docks at which the "Theodore Roosevelt" will land. As soon as the boat is docked attachments will be made with the apparatus set up on the boat, so that those on board may call up their Chicago offices from their quarters on the steamer.

FIFTEENTH ANNUAL CONVENTION OF THE INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION.

It is five years since the members of the I.M.E.A. had an opportunity of visiting Glasgow in connection with the Annual Convention, the occasion then being the meeting held in Edinburgh under the presidency of Mr. F. A. Newington. At that time the delegates paid a complimentary visit to Glasgow, almost as a matter of course, and were entertained by the Corporation, who are the keen rivals of their municipal brethren in the Athens of the North. Now, in 1910, the position was reversed. The Convention proceedings centred in Glasgow, and a day trip to Edinburgh formed one of the principal attractions of the programme. Progress in central station plant design and maintenance has been most marked during the time that has elapsed, and delegates to the Edinburgh Convention of 1905 who were impressed with the massive proportions of the Pinkston tramway units were keener this year upon live steam and exhaust turbines. The electricity departments of both Glasgow and Edinburgh have closely followed the developments of this class of prime mover, and each now has interesting examples of both patterns in use. In the Glasgow tramway power house at Pinkston, near the huge reciprocating engines round which much controversy raged when they were installed, a 3,000 kw. high-pressure steam turbine has been running for some time. Its diminutive proportions compared with the reciprocators are very striking.

For the convenience of members from London and the South of England who are attending the Convention, the Electrical Press (Ltd.) arranged for four special saloons to be attached to the 2 o'clock train from Euston on Monday. Some 80 members and guests availed themselves of this facility, which was greatly appreciated, the more so, since a whist drive served to pass the time very pleasantly. The consolation prizes in the drive were by no means the least valuable, consisting of a 12 months' subscription to THE ELECTRICIAN, "Electrical Industries" and "Electrics," the "Electrical Review," the "Electrical Times" and the "Referee." Music and stories also formed part of the programme, so that we need scarcely say that the long journey was shorn of all its tedium.

Among the engineers who are attending the Convention may be mentioned: Messrs. H. P. Acland, N. Appelbee, F. Ayton, G. G. Bell, H. Bell, J. A. Bell, H. C. Bishop, A. S. Blackman, T. W. Bloxam, H. R. Burnett, J. H. Cawthra, R. A. Chattock, J. Christie, S. Clegg, T. D. Clothier, A. Clough, H. H. Couzens, A. C. Cramb, J. Dalrymple, A. A. Day, C. S. Davidson, J. E. Edgecome, A. Ellis, R. F. Ferguson, S. Z. de Ferranti, E. E. Hoadley, E. M. Hollingsworth, W. W. Lackie, C. W. Mallins, A. B. Mountain, H. D. Munro, F. A. Newington, E. G. Okell, S. L. Pearce, P. J. Pringle, H. Faraday Proctor, C. A. L. Prasmann, W. M. Rogerson, T. Roles, M. Ruddle, A. H. Seabrook, C. E. C. Shawfield, D. A. Starr, H. M. Taylor, G. Tough, C. Turnbull, W. A. Vignoles, S. J. Watson, G. Wilkinson and C. H. Wordingham. There is also a large attendance of representatives of electricity committees; prominent among whom are Alderman G. Pearson, of Bristol, Alderman Sinclair, of Swanesa, Alderman J. P. Smith, of Barrow-in-Furness, and Councillor Willock, of Glasgow.

Tuesday, June 14th.

The Rankine Hall of the Institute of Engineers and Shipbuilders was well filled when the Hon. A. McInnes Shaw, Lord Provost of Glasgow, rose to give an official welcome to the delegates. As is usual on such occasions, the municipal "glad hand" was extended to the accompaniment of the permitted indulgence in electrical reminiscence. The speaker recalled his particular association with the early days of the electrical industry, and concluded with the well-worn phrase, long since deprived of its irritation, that "electricity was still in its infancy"; and this despite the rapid and important strides made in the last five years.

Mr. W. W. Lackie then read his Presidential Address, of which the following is an abstract:—

PRESIDENTIAL ADDRESS.

BY W. W. LACKIE.

After referring to the present position of the Association, which now numbers 416 members, and was being increasingly recognised as an important factor in the electrical world, the author passed on to general questions affecting electricity supply. There has been much progress since the Association met in Glasgow in 1901, under the chairmanship of Mr. Chamen, as is well illustrated by the following figures:—In Glasgow in 1901 electrical energy cost, including interest, depreciation and sinking fund, 2·96d. per unit as against 1·73d. to-day. Excluding the standing charges, the works costs then were 1·41d. per unit as against 0·562d. per unit to-day. The larger electrical undertakings throughout the Kingdom show similar evidence of development.

Very important work has been done by your council during the past year. Last August the Electric Lighting Acts Amendments Bill received the council's careful consideration, and the amendments made upon the Bill embodied in the Act now passed are practically all in accordance with the expressions of opinions received from the representatives of the municipalities interested. To the Scottish municipalities it was particularly gratifying that an amendment was accepted at the last moment protecting both authorised private companies and authorised municipal undertakings from unfair and unreasonable competition on the part of unauthorised companies.

In connection with the clause of the same Bill regarding the raising of capital by municipalities for the purpose of wiring consumers' premises, and the hiring-out of motors, &c., it is known to you that this clause was dropped out entirely. If the clause authorising the work in consumers' premises to be done "through a contractor only" had been passed, it would have been contrary to the existing Electric Lighting Acts and Orders, and undoubtedly would have been found quite unworkable. I do not know if the mover for the addition of the words "through a contractor only" realised that all municipalities would require, if these words became law, to engage a contractor to erect the main fuses and switches, and connect, disconnect, remove and repair all meters.

It has been alleged that the electrical industry has suffered through municipalities obtaining powers to raise money for electrical purposes. This, I am certain, is a fallacy. Municipalities have done much to advance our industry. In many burghs they undertook the supply of electrical energy at a time when no company would have ventured to do so. Further, they borrow money at a low rate of interest, the benefit of which is directly reaped by the public in a cheapened supply of energy; and nothing is, or can be, better for the whole industry than such a supply. It leads to more than an equivalent amount of plant being installed in consumers' premises, and the supply of such plant is, as a rule, left to private enterprise. Some kind of protection should therefore be extended to those municipalities who, after having acted as pioneers, now find their areas surrounded or invaded by private supply companies. These power companies can, as a rule, select their consumers, and this leads to unfair comparison in the same district between the rates of charge made by the municipality and those made by the private company. The supply authority, whether private or municipal, should therefore be protected. In like manner I am also averse to a municipal concern harassing a company in this way.

The question of depreciation and its relation to sinking fund is one that still remains undecided. Since the rate of sinking fund has been so seriously increased, any undertaking having a rate of not less than 3½ per cent. and a reserve fund equal to one-tenth of its capital is surely quite sound financially. As to what is depreciation, and whether it is dependent on efficiency and obsolescence, I should say in reference to these questions that:—

1. Depreciation of value is met by the sums set aside for sinking fund, if such sinking fund be properly calculated upon the probable life of the plant.

2. Decreased efficiency should be met by depreciation if the ordinary maintenance chargeable to revenue is not sufficient to keep the plant in its first state of efficiency.

3. Obsolescence does not mean, nor does it involve, depreciation. It is not true depreciation, but it is quite possible that a prudent

Digitized by Google

authority, owning works, might look to the advantage which would be gained by installing present-day plant, and so getting greater efficiency than would be obtained from antiquated plant. Such an authority would annually lay aside a sum for this purpose and might be found dispensing with old plant in favour of something more up-to-date, even although the latter might not have reached the end of its usefulness. Such a course, however, is not compulsory under the Electric Lighting Acts. It is not legal to create a deficit by setting aside a sum either in name of depreciation or of reserve fund. Only such sums as are profits are available for this purpose. Allow me to point out that the Court of Session in 1880 held that the deduction for wear and tear to be made under the section of the Act above referred to is deduction for diminished value as a means of earning income, and not as a saleable subject, and that inasmuch as the plant in question was undiminished in value for the purpose of earning income, no deduction from income tax charge could be made beyond repairs already allowed for.

In the machinery for the generation and distribution of energy, no very great change has taken place. There has been a good deal of serious depression, which was emphasised by the advent of the metal filament lamp, but we all believe that the metal filament lamp will do for the supply of electricity for lighting purposes what the incandescent mantle has done for gas lighting, and more also; but the immediate effect has been to cause many stations to cease putting down additional plant for a year at least. It has not been so necessary for increased lighting connections to be obtained as was at first thought, owing to the growth of the power load.

Much could be said in favour of the supply authority providing the consumers with lamps. Frequently bad lighting is found to be entirely due to defective lamps. In premises which are rented, whether for business or dwelling in, the rule now is that the proprietor in the first instance provides lamps, but there is no definite arrangement for these lamps being either of the most efficient type or renewable at stated periods. It is not uncommon for a tenant to rent premises where the lamps are of an older type and dim with age; this has naturally a prejudicial effect on electricity for lighting purposes. Even if the ingoing tenant, for his own satisfaction, bears the expense of new lamps, it is too much to expect that on his departure he should leave the good lamps he has put in, in place of the old ones he found installed at the time of entry; and cases have come to my knowledge where the outgoing tenants have substituted old defective lamps on the eve of their removal. It seems to me that in the end it would be for the best welfare, not only of the supply undertaking, but of the wiring contractors, if the lamps (which, after all, are the means of transforming electrical energy into light) were left to the supply authority, either to be supplied and the price included in the charge per unit, or sold direct to the consumer by the supply authority. If the former method were adopted, one lamp might be given for every 100 or 200 units used, and if the latter, the price would be, at most, net cost.

Very great improvements in heating and cooking appliances have been effected, and more extensive use of electricity is daily being made for these purposes.

Rapid growth of supply has brought to the front the question of rates of charge to special classes of consumers. For example, consumers with large and small demands; and extra long hour consumers. This is a question which is bristling with difficulties, but it is only by flogging at it that we can come to anything like a solution, and every time that an individual engineer boldly tackles the subject of special charges as regards small, large or long hour consumers he is helping those who find themselves faced with similar difficulties. A flat rate per unit is what is wanted by most people, and it appears to me that it may be possible to adopt this. Any flat rate adopted must be based on the maximum demand system, or, in other words, on the load factor of each consumer, and, where classification is possible, on the average load factor of any one class. For instance, in Glasgow we have a maximum demand system for both lighting and power. We might begin to charge flat rates to-morrow, but these rates would be the same as the average rate paid by each consumer during the previous year on the maximum demand system. The maximum demand would still be taken during the year and the average rate worked out. This would mean that we should have flat rates for different consumers or for various kinds of consumer, ranging from 3½d. per unit to ½d. per unit, decreasing from the former to the latter by tenths or even hundredths of a penny; but each rate would be the result of fair and just computation. A rating committee might be appointed, and sit once or twice a year to hear and settle cases in dispute. It is quite conceivable that such a method might lead to increased consumption of energy; for do we not find that consumers paying 3½d. per unit for the first 730 hours' use of the maximum demand and ¾d. thereafter, or an average price of, say, 2d. per unit, forget about the units they have got at the ¾d. rate and grudge the price of energy when the time comes to revert to the 3½d. rate? It is quite likely that many such consumers would regard a flat rate of 2d. as a distinct boon, and would not exercise the rigid economy which is often practised in connection with 3½d. rate. The rating committee might be appealed to, in cases of dispute, to settle the rate of any new consumers making a large demand.

One should be careful of accepting statements such as "20 H.P. for 1d." per hour, or passing criticisms on supplies of electrical energy at prices varying from 8d. to ¼d. per Board of Trade unit. The real cost is the total charge per horse-power per annum, including all material, labour, depreciation and interest on capital. The rate per unit is not a reliable criterion as to whether the supply is cheap or dear. Strange to say, it is the consumer who is paying, say, 3½d. per unit who complains that he is being overcharged to make up the deficit caused by the consumer who is paying only ¾d. Of course, it is the reverse that is true. The time may be approaching when, instead of charging a rate per unit we will charge so much per 10 units; this would enable us to make fractional reductions smaller than the minimum possible reduction of ¼d. per unit with the present method of charge. For instance, our rates in Glasgow vary from 3½d. to ¾d.; this would work out at 2s. 11d. per 10 units for light, and 7½d. per 10 units for power.

Where a fixed rate of, say £4 or £5 per kilowatt per annum is charged plus a low rate of ¼d. or ½d. per unit, the fixed rate can be reduced, but when the fixed rate system was tried 10 years ago in Glasgow by Mr. Chamen, we had serious complaints from lighting consumers because of their bills being as heavy in summer as in winter. Many of these consumers used practically no light in summer, and yet they received a substantial bill, say, for July or for August.

I cannot now do more than refer to the knotty question of specially low rates to users of a large amount of energy for an exceptional number of hours in the year; two remarks, however, perhaps ought to be made. It has been suggested that the municipal electricity supply undertaking should, in certain circumstances, give power supplies to large industrial concerns even at a loss, for the sake of the secondary profit that may accrue through the employment thus provided. I think this is not sound reasoning. The first duty of the supply undertaking is to see that all classes of consumers pay their due share of the standing charges on the capital expenditure necessary to provide plant to supply them. Another remark I wish to make is: it seems to me that it would be to our common advantage if those who have a number of large lighting or power users connected to their mains came to some agreement as to the basis upon which the rates of charge to such consumers should be founded. I think you will agree that the present lack of uniformity in our methods of charging is a fruitful source of trouble. Without properly understanding the question of electricity charges a consumer will quote one supply authority against another, whereas the local charge may not be exorbitant after all.

Alderman J. P. SMITH proposed a vote of thanks to the President for his address, and pointed out that it was becoming increasingly difficult for a president to incorporate new and interesting matter into the address. On this account, Mr. Lackie's effort would be the more appreciated for its choice of interesting subjects and the lucidity of their presentation.

Mr. C. H. WORDINGHAM seconded the vote of thanks, and recalled his early connection with the Association as one of its presidents. He particularly appreciated the onerous position of the President, involving, as it does, the occupation of much time, the exercise of tact and need for considerable self-sacrifice.

Mr. LACKIE then called on Messrs. A. C. Cramb (Croydon) and H. Collings Bishop (Newport) to read their respective Papers on "Commercial Progress." Each author gave a summary of his Paper and thus plenty of time was available for discussion. The Papers are reproduced elsewhere.

DISCUSSION.

Mr. A. H. SEABROOK (Marylebone) opened the discussion, and remarked that as he was mainly in accord with the Papers he would offer only constructive criticism thereon. His own sales installation department showed a profit of 40 to 50 per cent. on the prime cost of apparatus sold; consequently the local contractor could not complain of price cutting. Hire purchase, he thought, should be based on a two years basis unless best guarantees were forthcoming from the consumer. Twenty-five per cent. down and balance in two years, he thought, a necessity and not an alternative as suggested by the authors. The hire of arc lamps was a useful scheme in that it bound the consumers permanently to the undertaking. Mimeographed circular letters were comparatively worthless, sepa-

Digitized by Google

ately typed and signed letters being worth the time and money expended n them. The hire purchase of motors was to be commended because a change in horse-power, either larger or smaller, was needed it was a simple matter. The Lord Provost had referred to electricity as being in its infancy. Certainly this remark could be justly said of "business getting" in electricity supply. In Marylebone the services amounted to less than 40 per cent. of the premises in the area when he took over the undertaking. The question of canvassers was best settled by paying a man a small salary and a good commission. From his experience, a man worked more and frequented tea shops less on this system than when he received a higher salary and smaller commission. The bonus should be varied according to the class of supply obtained. He thought that Prof. Fleming's recent remarks at the Royal Institution, comparing electricity and gas for cooking and heating purposes, should be reprinted and distributed widely by electricity undertakings.

Alderman J. W. CROWTHER (Sheffield) gave a few facts as to business getting in Sheffield. Exhibitions, held annually for preference, were, he thought, more productive than a permanent show-room, and for this reason, they did not run a show-room in the central part of the city. Their two exhibitions in 1906 and 1909 had brought on a large number of electric furnaces for which a charge of 0·6d. per unit for energy was made. Small exhibitions of domestic applications were more effective than the more expensive large exhibitions. The bonus system for canvassers he thought mischievous, and press advertising had proved very disappointing. Regarding gas competition he considered this as likely to be more severe, and in Sheffield the price of gas was likely to fall as low as 11d. per 1,000 cubic ft.

Mr. C. H. WORDINGHAM felt that the day of the superior engineer and the appellant consumer were gone. Vigorous efforts to secure custom were now required. Mr. Cramb had rather overdone the specialisation of his suggested canvassing staff, and he pictured three experts of light, heat and power respectively presenting themselves to a hairdresser for his lamp, motor and curling-iron business. He did not approve of "funny" advertisements. People wanted facts. A leaf might be taken from the book of the gas interests by the production and publication of press articles which had an educative value to the lay newspaper reader. Facts might be driven home in this way. Electrical engineers were not as wily as their gas rivals in these matters. He felt that the contractor was the best friend of the station man, but was not quite fairly treated. His preserves should not be unduly encroached upon. On the other hand, it was necessary for the station engineer to act in an advisory capacity with consumers, and they should keep this well in view. Or the engineer should see that consumers were advised by genuine consultants, not by contractors. The small salaried canvasser he did not agree with. The words "good man, good salary and trust him," should be written in letters of gold in the committee room of every municipal electricity undertaking.

Mr. W. A. VIGNOLES (Grimsby) said that a reasonable commission should be paid to a canvasser, but that he should not naturally receive more than the engineer himself. The commercial department suggested in Mr. Cramb's Paper could only be organised in a large undertaking. The salaries of £2,000 which would have to be paid would only be merited on an annual turnover of some £100,000. In a small station most of the specialised duties would have to be undertaken by one or two men. In canvassing work his own men made a dead set for certain trades, and gradually brought each round to the service. The Joint Publicity Committee in London was doing good work, but something more was wanted. In newspaper advertising only indirect results were to be looked for. His idea was a scheme of national advertising, which would enable the supply undertakings of the country as a whole to benefit from educational advertisements in the great dailies. Such advertisements had a powerful educative influence, and were bound to bring results in time. He would like to see the American scheme of placing some 2,000 electric irons in a town for a short period, two or three weeks, say, tried in this country. There was good business to be got by bringing apparatus to the consumer for trial purposes. It was well to work in with the borough surveyor who had plans of new buildings deposited for his approval.

Councillor D. LIVINGSTONE (Hull) generally approved of the ideas in the Papers, and pointed to Hull as a model town in electricity business-getting methods. He thought their show-room was quite the best thing of its kind.

Mr. F. AYTON (Ipswich) detailed his publicity experience, which dated back over six years. As proof of the value of a canvassing department he pointed to a 25 per cent. increase in business last year. The canvasser should be paid a small salary and sufficient commission to secure the best results. He raised a loud laugh in making the startling suggestion that lady canvassers be brought into service to impress the value of domestic electrical apparatus upon housewives. To approach these dear ladies with male canvassers, or to bring the subject of curling irons, coffee percolators, &c., to "darling hubbies" by the same parties, was indiscreet. The sale of these necessary domestic appliances should be entrusted to ladies, and he was seriously thinking of training a number of fair damsels for the purpose. His own department had a turnover of £3,043, excluding £500 free wiring, on a total staff expenditure of £300, divided between an installation expert, foreman, canvasser and office boy. This represented 1¾ per cent. of the total revenue and 10 per cent. of the department revenue. There was no cutting of prices against contractors, and he found that 28½ per cent. profit could be obtained on apparatus sold. Their motto was "best work, best material and one price" for installation work. The cost per lamp point worked out at 8s. 9d., including fuse boards, and the price charged was 13s. 6d. Metal lamps were installed wherever possible. He always worked in with house agents to keep in touch with removals and new tenants. Much custom was obtained by being on the ground before the gas people. Press advertisements were not profitable, but tramcar advertising could always be recommended. It was always wise to keep the consumer, actual and prospective, posted up to date with the latest electrical contrivances. This paid in the long run, and was not a costly thing to accomplish.

Mr. MARK RUDDLE (Dublin) considered that business getting methods were very desirable and necessary, but that many undertakings were handicapped because they had no powers to do wiring. Concerted action on the part of the Association was necessary to give many of the provincial undertakings these powers, and so to remove a serious disability in the matter of securing new customers and keeping old ones.

Mr. E. E. HOADLEY (Maidstone) also referred to the necessity for wiring powers being conferred on those undertakings which at present laboured without them. He considered that the accounts of consumers should be paid to men who could say a few words on technical subjects to the customer, and thereby interest him in the further uses of electrical energy. He heartily approved of lady canvassers as a solution of the problem of domestic electricity extension. A show-room should, he thought, be filled with interesting pieces of apparatus and not be a mere warehouse of art metal work. More work ought to be done with electric signs, and particularly electric facia boards which were largely used on the Continent. With these latter the tradesmen could get day and night advertising with the same sign.

Mr. F. M. LONG (Norwich) pointed out the advantages of the Norwich system of charging (a percentage on the property assessment and 1d. per unit) in securing customers for bedroom radiators and other apparatus which came on during non-peak hours. They had 4,600 consumers in Norwich (population 111,000), and among them were many small consumers. These were charged on a maintenance basis of 1s. per lamp installed and 1s. per lamp per quarter, and with metal lamps this proved quite satisfactory. Some 1,000 metal lamps were in use in this way, and renewals were less than he had anticipated. Gas competition was very keen. To meet the charge of 35s. per gas lantern per annum made for shop lighting, including cost of gas, he charged 2d. per unit and £5 per pair of flame lamps used per annum. This had proved successful, and some 400 arcs were installed on this basis; also 125 lanterns with clusters of metal lamps.

Mr. A. C. CRAMB, in reply, remarked that the greater part of the criticism was constructive and could be easily met. His tables and data re staff duties and salaries were intended to be elastic. They should be fitted in with the size of station dealt with. He maintained, however, that in power installations it was better to have a man who made a study of industrial motor drives, as he could bring in the large consumer. What Mr. Wordingham had called the "Ally Sloper" funny advertisement was not to be altogether despised. Facts undiluted could not be forced upon the consumer. They had to be suitably clothed to be more readily acceptable. The gas articles were good enough, but could be improved upon considerably. National advertising schemes were being considered by the London Joint Publicity Committee and something would shortly be done. The contractor had not much of his sympathy because for years the field was his and he did nothing to cultivate it. There were good and bad contractors, and most were unenterprising. He instanced the recent spell of sultry weather, when his men were taking fans round under their arms selling to consumers, and not a single contractor's man was canvassing. Some scheme was required which would settle whether the contractor or the station should have the trade discount of 25 per cent. on apparatus sold and work done. He complained of the injustice of the British Parliament in discriminating between one undertaking and another in the matter of wiring powers. Croydon was immediately outside the Greater London area, and excluded from privileges which were enjoyed immediately across the boundary.

Mr. COLLINGS BISHOP, in reply, said that the terms for hire purchase given in the Paper were based on a high price for motors, but these prices were now tending to fall, so that the average rate would go up. Gas competition was not, in his opinion, relatively as great now as in the past. He agreed that the contractor needed to be dealt with diplomatically. He should not be thrown over, but as a rule he did not go far enough. He was too fond of pushing purely lighting business, and disregarded the importance of auxiliary apparatus. His experience of tramcar advertising was that it was so popular in Newport that he could seldom get a vacant space for the electricity department announcements. The small consumer problem might, he thought, be tackled on a fixed price per lamp basis where a row of houses was concerned. A pair of cables was run along under the roof and tappings taken to each house below. Any number of lamps might be installed, but two only could be used at a time, a current limiter being introduced as a check on the consumer. The scheme was not yet in operation, but would be shortly.

After a hearty vote of thanks had been passed to Messrs. Cramb and Collings Bishop the bulk of the party adjourned to the City Chambers, where they were the guests of the Corporation at luncheon. The toast list at this function was commendably short. After the loyal toasts there were those of the Association and the Corporation of Glasgow. The first was proposed by the Chairman, the Hon. A. McInnes Shaw, the Lord Provost, and responded to by Mr. W. W. Lackie, who referred to the growth of the Association and also the progress of the Corporation electricity department. The latter he

Digitized by Google

regarded as contributing to the remarkably low death rate in Glasgow, the distribution and use of electrical energy having an undoubted beneficial influence on the health of the community. Ald. W. Bruce (Sunderland) proposed the second toast, which was replied to by the Lord Provost.

Tuesday's proceedings concluded with a reception and conversazione at the City Chambers by the Lord Provost, Magistrates and Town Council of Glasgow.

Edinburgh, Wednesday, June 15th.

The whole of Wednesday was reserved for a visit to Edinburgh, where Papers were read in the morning and the afternoon was spent at various works in the district. The members left Glasgow at an early hour and assembled in the Free Gardeners' Hall, Edinburgh, for the reading and discussion of two Papers, one on "Exhaust Steam Turbines and Condensing Plant," by Mr. F. A. Newington (Edinburgh), and the other "Mixed Pressure Turbines," by Mr. Ashton Bremner (Burslem). The latter Paper was read by title in the absence of the author.

DISCUSSION.

Mr. I. V. Robinson (Richardsons, Westgarth & Co.), in opening the discussion, emphasised the importance of a high vacuum in the running of an exhaust turbine, and proceeded to describe an interesting kinetic air pump which his firm had developed. One of these pumps had been in operation for some eight months and was able to maintain a steady

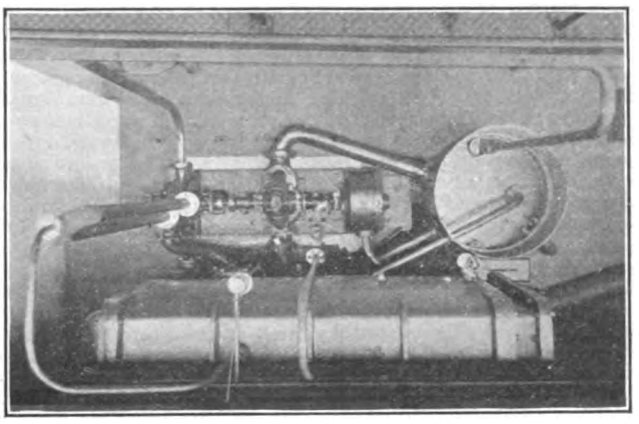
vacuum of 29 in. on a 750 kw. turbo plant. The air and vapour were drawn from the condenser under the action of a steam jet, and, together with the steam, were met by a water spray, which condensed the added steam of the jet. The ejector water was then encountered and the combined flow delivered to the discharge pipe. [The adjoining diagram shows a sectional arrangement and assembly plan of the kinetic pump. A close examination of these drawings, which are fully lettered, will make the action of the pump quite clear. A further illustration shows a view taken from above of one of these pumps placed in an engine-room basement, beside the condenser barrel.] The complete arrangement, Mr. Robinson explained, included a circulating pump for the spray and ejector water and a two-stage centrifugal pump. With the latter the first stage is connected to the condenser from which the condensed steam water, over and above the air and vapour which are removed by the steam jet, is withdrawn and delivered against a static head of 8 ft. into a pipe, the top of which is connected to the condenser barrel. The connection ensures that the first stage of the pump (known as the head and pressure pump) shall discharge only against this head. Further, a positive head is thus secured for the suction side of the suction stage of the same pump. This second stage discharges the condensed steam water to the sump surrounding the ejector whence the boiler feed is drawn. [In the drawing the two pumps are shown driven by a small Curtiss turbine.] The pump dealing with the water spray and jet keeps this water constantly circulating from the sump. The advantage of the arrangement was that the latent heat in the steam jet was not given up to the circulating water, as in the case of a vacuum augmentor, but to the hot well, which was raised to a temperature 10 deg. or 15 deg. above the temperature corresponding to the vacuum. The apparatus ran with



View from above of Richardson's Westgarths Kinetic Air Pump.

the minimum of attention, being entirely rotary with ring-oiled bearings, there was but a single pumping unit, and the space occupied was extremely small.

Mr. C. H. Wordingham remarked that there appeared to be a sudden passion for exhaust turbines among station engineers, many of whom had evidently only just discovered that condensing was possible. The use of sewage water for circulating purposes was most interesting, but he inquired whether corrosion troubles had been experienced in the condenser tubes and also if the health of the employés was affected. Small plants were necessary at first in certain stations in spite of all that critics might say. He asked for details of the current density at which Mr. Newington worked the carbon brushes on his turbo-generators and also what coupling he used between turbine and dynamo.

Mr. S. Z. de Ferranti (President I.E.E.), who was loudly applauded on rising, said that the Papers would help to impress upon station engineers the value of their exhaust steam. In considering the introduction of exhaust turbines he thought the use of a specially designed machine, as distinguished from one manufactured under competitive conditions, should be carefully weighed. So many important factors contributed to the result aimed at that the question merited more than ordinary deliberation. Unless this was done, less value would be obtained from the exhaust steam. The whole problem was, he thought, somewhat involved, and the exhaust turbine appeared to be something of a makeshift at present. He had considered the use of exhaust turbines in a number of the large stations in this country and had obtained some fascinating figures of economy. The position might be looked at in the light of a proposition whereby manufacturers would contract to deal with some particular station and undertake to improve the operating efficiency, even if it involved scrapping the present plant and putting in entirely up-to-date machinery. That would be rather a drastic measure, and could not be looked for at present, though some development might make it necessary at any time.

Mr. C. E. C. Shawfield (Wolverhampton) congratulated Mr. Newington on his successful application of the sewage water for purposes of condensing. He inclined, however, to the belief that exhaust turbines were of doubtful utility, and that reciprocating plant was better scrapped and steam turbines put in. Capital would certainly be saved. Mr. Newington obtained 2,700 kw. from his two units at a capital outlay of £9,650, which included condensers and switchboard, but not pipes, strainers and cost of breaking into sewer. A 3,000 kw. live steam turbine could, he thought, be obtained for about £8,500. The average figure of 22·2 lb. of steam per kilowatt-hour seemed a high figure, but no doubt included stand-by losses. Probably a nearer figure was 19 lb., and, compared with this, a high-pressure turbine on the same vacuum would do 17 lb., and only half the size of condensing plant would be needed with less circulating water. In his own station, where three 500 kw. reciprocating engines were initially installed, he found that it was more economical to put in a 2,000 kw. high-pressure turbine as the extension plant, and not an exhaust turbine.

Mr. T. W. Bloxam (Belfast) had similar exhaust turbo units running in Belfast, but said that he was principally concerned with commutation troubles. The carbon brushes at first used overheated the commutator when the tension of the springs holding the brushes against commutator was increased. The commutator would also expand under the increased temperature. A ventilated commutator with flexible end straps and several other modifications was, however, being fitted by the makers, and he hoped would give better results. He was not sure if these direct-current turbo-generators should be self-exciting or separately excited. The circulating water in Belfast contained a quantity of rubbish which

Digitized by Google

blocked the strainer in the intake pipes, but he found it possible to free the strainers by pumping back through the pipes about twice a week, the particular pump, of course, being out of service at the time.

Mr. R. BIRKETT (Southend) considered that enough attention was not paid to load factor in this question of exhaust turbines. In a station like his own, with a 16 per cent. load factor, he would probably not have exhaust steam, except during an hour or two daily, which would warrant the running of such a turbine at all. He obtained very good results with his reciprocating plant, averaging 23 lb. of steam per kw.-hour the year round. He employed successfully an air condenser of the Ledward type, which saved £900 per annum in water alone over the previous circulating water and cooling tower arrangement. It would also deal with twice as much steam and cost less to run than the fans on the old cooling towers.

Mr. S. L. PEARCE (Manchester) thought that before any engineer committed himself to exhaust turbines he should have a clear idea of the principles under which such turbines operated. The turbines required to be designed to get the greatest possible amount of work out of the steam. The importance of a good vacuum must be kept in mind, as without it exhaust turbines were quite out of the question. An increase of the vacuum from 27 in. to 28 in. represented an increase of 20 per cent. in the heat units utilised. But high vacuum was not always easy to obtain, and the capital cost of condensing plant and pipework often detracted from the value of the results. Mr. Newington's statement in the Paper, that exhaust turbines might be generally recommended for the extension plant in reciprocating stations, needed to be accepted with caution, as it was by no means proved. Some interesting figures had been obtained by Mr. Stott (U.S.A.) in connection with the installation of exhaust turbines at the Interborough Rapid Transit power house. A 5,000 kw. exhaust turbine was there installed in connection with the 7,500 kw. Manhattan engine type units. These resembled the engines installed in the L.C.C. tramways Greenwich power house, but he (Mr. Pearce) thought that the Manhattan engines were not in themselves economical, consequently the favourable figures shown by Mr. Stott were not reliable. He referred members to Mr. Stott's Paper for details. He had considered the use of exhaust turbines at Manchester for the Stuart-street station extensions, but came to the conclusion that they were not needed, because a saving of only ¼ lb. to ½ lb. of steam could be shown. He was accordingly extending with live steam turbines.

Mr. FARADAY PROCTOR (Bristol) suggested an alternative to Mr. Ferranti's proposal to instal new turbines and scrap the reciprocating engines. He thought that the turbines might go in, but the reciprocating plant be retained as a stand-by. It was not a matter of the capital cost of the new plant, but of the charges on the buildings and foundations of the old plant.

Councillor LIVINGSTONE (Hull) inquired whether there was any shortage of the sewage water for circulating purposes during very dry weather.

Mr. F. W. PURSE (Watford) thought that the figure of 33 per cent. saving given in the Paper was misleading, in that it was not based on the capital charges. In his own case his committee might gather that the particular figure given would apply to any station which installed exhaust steam turbines.

Mr. R. H. CAMPION (Dewsbury) thought that something should be said in favour of the mixed pressure turbine. He was able to obtain 360 kw. from his exhaust steam, and could also run the turbine on live steam. The radial commutator had done much to solve the problem of commutation and also in the provision of efficient ventilation of commutators.

Mr. F. A. NEWINGTON, in reply, said that there had been no trouble through corrosion in the condenser, nor any difficulty in the matter of nuisance or ill-health of the staff. The scraping arrangements were not yet perfect, but would be improved later. Figures re the current density on the carbon brushes he would have to communicate to the "Proceedings." He thought that the high-pressure turbine showed up well on paper, but anything could be proved on paper. As to the scrapping of plant, he personally would not feel inclined to go to his committee and suggest the wiping out of some 8,000 kw. of reciprocating units. Mr. Shawfield had in his criticism forgotten the boilers. Regarding excitation, in their own case the separate exciter had been recommended by the makers and they had accepted it. He could not say if self-excitation was better. He still held to the opinion that there were many stations with reciprocating engines of the Willans type which could profitably introduce exhaust turbines as extensions. The commutation problem had proved somewhat vexatious, but they had been able to run satisfactorily for some time now. In dry weather the sewer water was kept up by the greater number of baths used, and further the load was always lighter.

Mr. W. W. Lackie proposed a hearty vote of thanks to Mr. Newington for his Paper, and the party afterwards adjourned to the Music Hall, George-street, where they were entertained to luncheon by the Corporation of Edinburgh. The Lord Provost presided and officially welcomed the Association to Edinburgh. The speakers at the luncheon were Judge Stephenson, convener of the Electricity Committee, Edinburgh; Alderman Pearson (Bristol); Mr. W. W. Lackie, and the Lord Provost.

The afternoon was spent in visits to Messrs. Bruce Peebles' works, the McDonald-road Electricity Works and the Marine Gardens, the latter being thrown open to the members of the Association by the management.

LATEST FROM GLASGOW.

BY TELEGRAPH FROM OUR OWN CORRESPONDENTS.

Glasgow, Thursday, June 16th.

The meeting this morning was again in the Rankine Hall of the Institute of Engineers and Shipbuilders. Mr. W. W. LACKIE, in opening the meeting, explained that the morning's proceedings were somewhat of an experiment, since no Papers were being read, but, instead, an opportunity was afforded to members to discuss two matters of vital importance in central station operation and expansion—namely, (1) "Advantages of Continuous Records of Costs and of Steam Consumption," and (2) "Cheapening of the Cost of Mains and Services."

ADVANTAGES OF CONTINUOUS RECORDS OF COSTS AND OF STEAM CONSUMPTION.

Mr. G. WILKINSON (Harrogate), in opening the discussion on Records of Costs and Steam Consumption, said that at Harrogate the steam costs were made up by the switchboard attendant nightly, and were posted in weeks and had great influence in keeping the costs at a low figure. He thought that air leakage into flues was a frequent source of loss; and by using a special cement which had an affinity for metal and brickwork, a large factory station had saved £500 per year. The efficiency of an economiser could be much increased by keeping the inlet water at a low temperature. Experiments with a 280-tube Green's economiser, dealing with 1,300 gallons of water per hour, reducing the temperature of the inlet water to 94°F. showed an increased efficiency of 26 per cent., representing a saving at the coal heap of 4·4 per cent. To reduce sweating, a pipe might be led from outlet of economiser to the suction side of the pump. Condensation in the steam pipes was a great source of loss. Water often accumulated at certain points and blew over intermittently into the engines and turbines. At low loads, condensation losses might equal 2 to 4 per cent. With turbines the steam trap water should be returned direct to the boiler and not drained into the sump. Ferranti-Hopkinson valves, if used horizontally, sometimes caused water to collect at each side in the contracted portions. At Harrogate trouble from this cause had been avoided by draining the water between the valves. He instanced Harrogate as an example of the value of keeping records. In spite of a 5 per cent. drop in load and 4 per cent. increase in the cost of coal they had reduced the cost per unit generated by 10½ per cent.

Mr. C. E. C. SHAWFIELD (Wolverhampton) remarked that it was most important to keep continuous station records. He asked for apparatus to record hourly the total number of pounds of coal per unit generated. This item varied enormously during the day. His own tests were somewhat paradoxical, as he found on night shift that an increased production of units caused a reduction in the coal consumed. The whole of the condensed water should preferably be recorded on a single instrument, instead of on separate recorders on each engine. The make-up feed water should also be separately recorded to indicate the loss in the condenser. His experience with CO_2 recorders showed that these were not altogether reliable. He thought that tests made with portable Orsat apparatus were more accurate.

Mr. F. E. AYTON (Ipswich) thought that the efficiency of other parts of the system required greater attention than the station, and instanced consumers' meters. He agreed that CO_2 recorders needed continual attention. He used the Krell type, but dust in the sampling tubes was a source of trouble, particularly at rubber joints. Air leakage also might cause errors. He thought that the repairs to recording instruments would become costly after some years. The principal value of the CO_2 recorder was to indicate air leakage. He recommended glazed bricks or a mixed tar and pitch coating for the flues and brickwork. He found that cement made a grand firebrick, and that Portland cement for flues and settings gave permanent results. Sand cement generally cracked. In regard to scrapers for economisers, an improvement was wanted. He thought the use of steel tubes in the Horseferry-road station was an advance, as the surface was smoother. The heavy coal consumption on night load enabled street lighting to be done at a low cost.

Mr. C. H. WORDINGHAM thought that central station engineers were becoming meter maniacs with too many records. It was better to make careful tests at longer intervals, and to aim at the greatest possible simplicity. It was better to return the heat in steam trap water to the boilers than to measure condensation losses.

Mr. F. A. NEWINGTON (Edinburgh) had tried to reduce the amount of moisture in coal by tests from which reductions in contract price were made; but he found a difficulty in working such an arrangement. Alternative prices for coal with 10 per cent. or indefinite amount of moisture showed a difference of 3d. per ton, and pointed to the fact that it was not worth pressing for. He thought coal merchants knew more about coal than station engineers. He considered that bomb calorimeter tests and hourly records of coal consumption were of little value.

Mr. MARK RUDDLE (Dublin) thought that keeping detailed records in large stations was impracticable, and the time of the staff was better spent in inspecting and checking the plant. He considered that the only important test was the calorific value of the fuel.

Our report of the proceedings at Glasgow yesterday (Thursday) is concluded on p. 405.

PAPERS READ AT THE CONVENTION OF THE INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION.

We give below abstracts of the four Papers which were read this week at the Convention of the Incorporated Municipal Electrical Association. The first two Papers, namely, those by Mr. A. C. Cramb and Mr. H. Collings Bishop, which deal with commercial progress, were read at Glasgow on Tuesday last; whilst the Paper on "Exhaust Steam Turbines and Condensing Plant," by Mr. F. A. Newington, and that on "Mixed Pressure Turbines," by Mr. A. Bremner, were read at the meeting at Edinburgh on Wednesday. An account of the discussion which followed the reading of these Papers will be found on an earlier page.

COMMERCIAL ADVANCEMENT OF ELECTRIC SUPPLY.*

BY A. C. CRAMB.
(Chief Electrical Engineer, Croydon.)

Summary.—The author urges the necessity of a vigorous campaign for developing the use of electrical apparatus, and indicates on general lines how this campaign should be organised.

In the past comparatively little attention has been bestowed upon the commercial development of electric supply, and more particularly does this refer to undertakings owned by municipalities. The enormous reduction in revenue brought about by metal filament lamps, however, has made this a vital question. The state of affairs in this country as contrasted with that in America is well illustrated by the following extract from some articles written by an American engineer as a result of a careful investigation of electric supply in this country: "This condition is almost universal in Great Britain—aggressive work by the gas interests and procrastinating somnolence on the part of the electric departments." Few who have given this matter careful consideration will be inclined to disagree seriously with this criticism.

Electric supply is as much a competitive business as any other, whether in the domain of lighting, power, heating or in almost all the numerous uses to which its suitability has been demonstrated. This being so, a proper expenditure on business getting is essential if development is to be satisfactory. Of primary importance is a thorough scheme of organisation of the commercial side of the business, modified to suit the conditions of each particular undertaking.

In undertakings of any appreciable size the duties of general management will occupy so much of the engineer-manager's time as to render it necessary to have a competent sales assistant, working immediately under his direction to control this portion of the business. This appointment is an important one, and the salary should be such as to obtain a good energetic engineer with sound commercial experience and with good organising capacity. At the moment there is a lack of suitable men, but many engineers with natural aptitude for business getting would soon become fully competent to carry out this work if many posts with a sufficiently remunerative salary were offered. The business-getting men must know their business, have faith in their wares, be courteous, of even temper, active, tenacious, reliable, and withal close students of human nature.

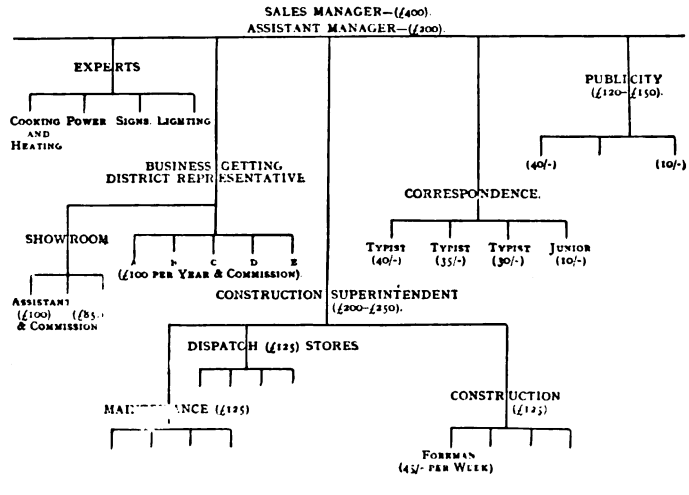
The organisation of the staff on the commercial side depends considerably on the policy of any particular undertaking. A large number of undertakings at the present time work under very restricted powers. What is legal in one area is called illegal in the next, which is the acme of absurdity. The public who have been educated up by the gas companies to expect to be able to buy, hire and hire-purchase almost everything in connection with gas supply, naturally and rightly expect the same of electrical supply. Every manager of electric works can testify that gas companies are able to hold and extend their business on a scale which would be impossible were the relative positions on an equality.

Gas companies generally supply under the condition that increases in dividend are co-dependent on a reduction in price to the public. Rather than reduce the price of gas, however, gas companies use large sums of money that should go to the public in reduced price for gas, in fitting up houses free, or nearly so, and in doing a great deal of work for the public with a view to keeping out the electric supply, which generally has not such powers.

In the case of undertakings in which the business is confined to the sale of electrical energy, the sales staff should consist of (in undertakings above a certain size) a sales manager (£150–£300), district representatives (£78–£104 and commission, or £120–£180), an advertising assistant (£100–£120), specialists each in power, lighting and signs, and heating and cooking (£120–£250), a show room attendant (£100–£150) and a clerk (£80). It is advisable to pay the manager a fixed salary. District representatives are generally, however, paid a salary with commission. The salary should vary from 30s. to 40s. with commission of 3½d. per 35 watt lamp, 2s. 6d. per brake horse-power in motors, and pro rata for heating and cooking apparatus. Some managers, however, prefer to pay a fixed salary, as there is otherwise, they think, a tendency to overload a consumer. It is advisable to divide the area of supply into districts, allocating a man to each district. Each man should make an average of 30 calls per day. A record should be kept of the number of calls per order for each man—in one case this works out at nine.

The advertising assistant's salary is sufficient, because literature and advertisements can be arranged through the joint publicity committee. The expenditure for commercial development under these conditions should be in the neighbourhood of 2 to 3 per cent. of the annual revenue, and should be charged to joint working costs.

When sales and installation departments are carried on, the staff engaged would be a much larger one; the expenditure on sales, installation, hire, &c., should be covered by profits on this work, but the remaining expenditure, including publicity, should be charged



to working expenses, as in the former case. The above diagram shows a suggested arrangement for such a staff in the case of a large town.

The construction department will be divided into two branches, maintenance and construction. Maintenance will control hire and hire-purchase of arc lamps, motors, heating and cooking apparatus, in addition to maintenance contracts, which have proved of great value in retaining consumers. Construction will be responsible for all new work. The salaries set against the different positions are a general guide, but can be taken as about fair. The bonus should be paid on net sales, disconnections being debited.

Hire and Hire-purchase.—For hire a gross profit rental of 30 per cent. should be paid, made up as follows:—Redemption of capital, 15 per cent.; interest, 5 per cent.; repairs and maintenance, 5 per cent.; contingencies and other charges, 5 per cent. The hirer must pay for any breakdowns not due to fair wear and tear and fire insurance. The rental to include inspection and maintenance other than above. For hire-purchase (two to five years) the list price of the motor, and a further 15 per cent., should be taken and divided into equal parts. Alternatively, 25 per cent. of cost paid in advance and the remainder in eight quarterly instalments is a good plan if it can be arranged.

Arc lamps are hired at inclusive prices, and in one case the charge is £8. 4s. per annum up to 800 hours use per annum, payments to be made in advance, 2½d. per lamp per hour being charged for excess use. M.F. fittings should give good results on the same principle.

Electric vacuum cleaners, for hire, including delivery, at a rental of 7s. 6d. to 10s. per day, should have a fair demand. Cooking and heating apparatus must be hired at liberal rates to cover depreciation.

Show Rooms.—It has been proved by actual experience, and will be conceded, that a central position in a good business thoroughfare must be selected. Having secured a position, it is advisable to arrange the frontage in an attractive manner, and as much as possible should be devoted to window space, in such a way as to make an attractive show of electrical apparatus to passers-by. It is important that the premises should be kept clean and bright. Every effort should be made to get as many people as possible to call. The collection of accounts should be made from these premises, consumers having to walk through the show rooms to reach the cashier, so that existing consumers can be kept in close touch with new ideas and new apparatus, and the benefits of such demonstrated to them. Undertakings not availing themselves of this opportunity are undoubtedly losing many opportunities of increasing business. Complaints can also be much more easily and effectively dealt with in this manner.

If the premises are sufficiently extensive, it is advisable to fit up certain small rooms to demonstrate under normal conditions the varied uses of electricity in the household, and, in fact, every opportunity should be taken so to arrange the electrical apparatus that its operation can be demonstrated in such a way as to carry conviction as to the advantages of its adoption. All articles should be clearly marked with the list price and the cost of current per hour, and good illustrations of the many applications of electricity should be hung from the walls.

The show rooms should be in charge of a qualified man, able to explain accurately and convincingly all the good points of the apparatus, and to give information on all matters appertaining to electric supply without worrying the visitor.

The outside of the premises should be well lighted by night; an illuminated facia helps to make the premises attractive, and will lead to orders for similar business. A large sign projecting at right angles from the building, so arranged that the wording can be changed, will be found to be a great advantage.

Exhibitions.—Exhibitions at intervals have proved to give very satisfactory results in increased business when well arranged and run on business lines, and are popular with the public. The out-of-pocket expenses should not exceed £50 to £100, according to the size of the town. In large towns a booth to give demonstrations is useful in large stores, bazaars, &c.

Advertisements.—A good business catching system of advertisements is essential to back up the canvassing staff and to carry on the large work of educating the public to things electrical, which is so necessary. This should be done by (*a*) Eye-catching advertisements in the local press, backed up by chatty paragraphs on new apparatus or work carried out. Church magazines are also useful for domestic applications. (*b*) Posters on hoardings which should be full of human interest and of artistic merit. (*c*) Showcards distributed in contractors' windows. (*d*) Artistic calendars distributed to tradesmen. (*e*) Tramcar advertisements. (*f*) Illuminated signs &c., perhaps, the most effective of all if properly thought out.

Circular Letters.—These and pamphlets dealing with the various applications of electricity, got up in an attractive manner, should be regularly circulated amongst the householders. A fair expenditure for advertising and publicity literature should be in a medium size undertaking 0·3 to 0·5 per cent. of revenue.

A joint publicity committee, representing company and municipal electric supply interests, and controlled by the manager, has recently been formed, and it should, in time, have a very material influence in developing the electric supply throughout the country. The committee will issue posters, pamphlets, and carry on all the work necessary for the purpose of commercial development of electric supply, and should be supported by every undertaking in the country. This committee may, at a later date, act as a registry for the commercial staffs of the undertakings.

A good office system is necessary in connection with the business-getting department. A card system can be made good and efficient use of. A record of all premises should be kept arranged in street numbers alphabetically (a suggested form for this purpose is given by the author), and the cards in the order of the street numbers. The back of the card contains a record of the date of calls, canvasser's initials and the result of such calls. It is further advisable to keep separate files of business premises, power users, &c., so that these consumers can be dealt with on special lines.

A scheme which in practice has worked well is to give a registered number to each premises and have separate dockets for same; all correspondence is filed therein, giving a complete record of all information respecting each particular installation.

Canvassers should be provided with a book of data likely to be useful to them, and each day they should submit a report on calls made. These particulars, after inspection by the sales manager, should then be entered up on the card by the show-room attendant, or in large undertakings by the clerical staff. Each man should have a diary, in which he should enter up at the proper dates any calls it is advisable to make in the future. A close watch must be kept on new premises being erected, and it is important to obtain early notice of premises let.

Treatment of consumers should receive careful attention. Complaints should be received in a sympathetic manner, and the confidence of the consumer obtained by courteous treatment. Such a course often leads to recommendation and increase in business. A list of unused services should also be kept, and these should receive occasional calls.

Heating and cooking is a branch of the business which in the past has not made much progress. Certain small lines, however, such as electric irons, should be good revenue-earning articles, and should be vigorously pushed. These should be placed on 14 to 30 days' trial, and 60 to 80 per cent. should be sold. An electric iron should produce a revenue of 15s. to 25s. per annum. Electric cooking is retarded more by the initial cost of the apparatus than by the cost of current, and a progressive scheme of hiring out is necessary.

Attempts at a more active business development of the supply undertaking have been accompanied by hostility from the contractors. There are two alternatives for the future, either co-operative arrangements between the contractors and the supply authority, or a vigorously conducted sales department by the latter. The author is of opinion that the sales department would bring a more rapid increase of business, and must be the final solution of the problem, as already clearly proved by the experience of the gas companies; but the former scheme being properly supported might produce useful results. The difficulty of attempting co-operation, however, seems mainly to be due to trade jealousy amongst the various contractors in any particular district.

THE COMMERCIAL PROGRESS OF ELECTRICITY UNDERTAKINGS.*

BY H. COLLINGS BISHOP,
(Chief Electrical Engineer, Newport, Mon.)

Summary.—The author describes the commercial development of the Newport electric supply undertaking during the past three years, discussing installation work, arc lamp hire, hire purchase schemes, charges, gas competition, free or assisted wiring, &c.

The past three or four years have seen the development of the commercial side of electrical undertakings to a far greater extent than at any previous time. Engineers have recognised that they must pay as much attention to that side of the business as they have done in the past to the engineering side, so that at the present moment electrical engineers have practically double duties to perform.

In the undertaking managed by the author the progress made in the past three years is, in his opinion, satisfactory, but still open to many improvements, chief amongst which may be mentioned the question of show rooms. At the present time no town need suffer from the want of advertising matter, as plenty can be obtained free from the various manufacturers if one is prepared to push their goods, and there is more than one company in existence which is prepared to supply any amount of literature in return for the coin of the realm. As to whether advertising matter so obtained is suitable must depend to a great extent on local conditions. Personally the author does not consider it altogether advisable to depend on matter made up in London as a suitable means of advertising, say, the Newport undertaking, a hundred and fifty miles away; and he is of opinion that the correct way to deal with the problem is to make up your own advertising matter to suit your special requirements, even though the standard of literary art may not be up to that of the expert.

The author has spent a good many years in America, but has not returned with the American idea of advertising, which necessitates dumping a postcard or letter on your breakfast plate every day until, from sheer exhaustion, you succumb and give an order. In Newport the sending of numerous letters, postcards, &c., was tried for some time but the results were not nearly so good as dealing individually with prospective consumers, and using your judgment when to give them a rest. Circularising specialities is another matter and can very well be done in the first instance by circular, to be followed by a call showing the article you want to introduce. When that article is likely to be suitable, such, for instance, as an iron, it should be left for a week's free trial. Nine times out of ten this will result in a sale. The essence of successful advertising is good judgment.

* Abstract.

Canvassing is the most important of all the departments connected with the commercial development of electrical undertakings. Payment by commission should not, in the author's opinion, be indulged in. His advice is, given a good man, pay him a proper salary and trust him. If a commission is necessary to make him look after your interests get rid of him, he is no good to you.

Two or three years ago the Newport Corporation appointed a combined canvasser and illuminating engineer, and the appointment has been an unqualified success, not only in the way of obtaining new consumers but in satisfying those who grumble. He has also been able to cover practically the whole of his salary by the casual sale, during his rounds, of lamps, irons, radiators, &c. The appointment has undoubtedly resulted in more contented consumers, less grumbling, and increased business, and the author would strongly advise those undertakings which have not launched out in this department to do so at once.

The mode of procedure in Newport has been as follows:—The canvasser works directly with the consumer or prospective consumer and reports daily to the chief the result of the previous day's work, and generally discusses the work in hand. By this means there is a minimum of delay in giving the prospective customer a definite reply, the canvasser becomes daily more acquainted with the policy of his chief, and is gradually able to deal more quickly with customers, and when the necessity arises of taking the responsibility of giving a decision on a matter at the moment, he is able to settle without feeling that he has taken any risk of disapproval. There is no doubt that a customer likes the man who has called upon him to be able to give a decisive reply without having to wait whilst the matter is referred to the office, and the close co-operation between the chief and the canvasser enables this to be done. Another important point when dealing with prospective consumers is to guage the correct time for the manager to step in and see the new consumer. This refers rather to the smaller jobs, the experience of the author being that in the larger jobs he has to do a great deal of the negotiating himself.

Installation Work.—There is no doubt that, were the field free, the electrical undertakings are in an excellent position for dealing with all the necessary installation work for their own consumers, and a good percentage of electricity users prefer that all repair and installation work should be carried out by the undertaking. Newport, which possesses full powers for dealing with all work connected with the undertaking, has so far rested content with carrying out such work as has been directly thrust in its way and in carrying out work under the hire or hire purchase systems. The general run of work has been left to the contractor. The number of consumers who now send direct to the electricity department is, however, growing rapidly, showing that they really prefer the work being carried out by the supply authority.

One is often asked, What is to become of the contractor? The author's reply would be that the properly trained and conscientious contractor has little to fear, but the man who becomes an expert in a night must, in the interest of the whole industry, go. A great deal of harm is being done by these men, and also by some of the large plumbers and ironmongers, who often put on an inexperienced man as electrical foreman and leave the whole department to him.

Motive Power.—In the author's case he has yet to find the consumer who discards electric power once he has started, except due to failure in business or other like cause. The ease of starting, and the knowledge that the power is always available for use are strong arguments in deciding people to change over from older methods of motive power to the more modern one. It is, however, necessary to run the hire department upon business lines. Ten per cent. to cover interest and all other charges, based upon the cost price, is bound to end in a loss to the department. Neither does the author consider it at all necessary to make the hire rate very low in order to obtain consumers. In Newport there has been no difficulty in obtaining 20 per cent. return on the cost price (the rates obtained in Newport for the hire of various sizes of motors are given in the Paper).

Arc Lamp Hire.—This is a department that has not been started by a great number of undertakings, nevertheless it is one that has many points worthy of consideration. There are two chief reasons that deter consumers from installing arc lamps, viz., first cost and the bother of trimming and cleaning. The author has found it most successful to undertake both duties, and in Newport there are at the present time 283 arc lamps on hire from the Corporation. The whole of these lamps are maintained by the Corporation for an inclusive fee per hour (in use) for current and carbons. In addition, there are 55 lamps owned by consumers, but maintained by the Corporation at a given sum per annum. There is no doubt that lamps so maintained give better results than when trimmed by the consumer.

The rates charged in Newport are as follows:—One 360 watt alternating lamp, 2d. per hour; one 400 watt alternating lamp with metal core (yellow) carbons, 2½d. per hour.

The rates charged for the hire of the lamps are as follows:—One alternating lamp and transformer, £2. 8s. per annum; two alternating current lamps, £4. 3s. per annum; four direct current lamps, £6. 18s. per annum.

Hire Purchase.—In this department we deal with almost any kind of apparatus that a consumer may require, both for lighting, heating, and power, and we vary the payments from one year to five years as may be required. The business done has been fairly good, without unduly pushing it; that is to say, if we think a consumer is prepared to buy outright we leave him to the contractor, but when we know it means deferred payments then we push the scheme for all it is worth. The author has found this scheme popular, even amongst those who are able to pay outright, for the reason that they like to have the maintenance in the hands of the Corporation.

Inspection.—In 1906 the author mentioned the question of inspection, and was criticised by one member as advocating red tape. The author abominates red tape of any sort and keeps all agreements, applications, &c., down to the smallest point, and for the same reason the published regulations are as short as possible. But he is still of opinion that some form of inspection is required, and the chief point to consider is, who is the right authority to undertake it? It used to be said that this should be done by the municipal authority, but now that so many corporations undertake installation work themselves it is questionable if they are the right ones to do inspection of work that may be done by a competitor.

Charges for Energy.—It will be agreed to, by some at least, that a general flat rate, although simple, is not satisfactory because it does not afford that flexibility that is necessary. The maximum demand system has been found wanting by many, and the town that has four pages of varying charges is laughed at by many engineers and grumbled at by the poor consumer, who does not know which to adopt. At the same time the author ventures to say that there must be a reasonable number of varying charges to permit him to satisfy the most difficult prospective consumers that it will pay them to adopt electricity. The rates in force in Newport are given in the Paper.

Gas Competition.—The author ventures to say that this does not exist to nearly the same extent that it did a few years ago. It is now strenuous fighting on the part of our rivals to prevent consumers migrating to a really healthy illuminant. Where competition really does exist is with the small consumer, who, at the present time, uses gas, oil or candles. Here there is a great field for activity. The competition in street lighting is dead. The advent of the flame arc for main streets and the high candle-power metal lamp for side street lighting has put that necessary finishing touch of superiority which makes it most difficult to raise arguments in favour of any other form of illuminant. One is able now successfully to attack that stronghold of the gas company—heating, and the gradual increased consumption in heating units that is being made each year is bound to tell in time.

Free or Assisted Wiring.—Many schemes have been tried for inducing small consumers to take electric light by offering to wire premises free or for a small rental, but there are not many cases where it has been a success. A better plan, in the opinion of the author, is to put forward the prepayment meter; and in Newport considerable success has been obtained in this line, some 50 to 60 meters having been installed during the past seven or eight months. This, however, does not overcome the difficulty of obtaining the very small consumer whose demand does not exceed two or three lights. Prepayment meters in these cases are no good because the revenue allowed in the charge made is not sufficient to make a sufficient return on the cost of the meter, and the author now puts forward for consideration a scheme for the inclusive rental of wiring and energy.

Briefly the scheme is as follows:—To charge a weekly rental for current and hire of fittings; to use a cheap form of surface wiring; a variable weekly rental according to the time of the year; an arrangement by which all rooms can be wired and a varying rate charged according to the number of lamps it is desired to have power to light up at the same time; a locking holder to minimise the theft of lamps; a scale of weekly rents for the varying conditions that may arise.

The charges shown on the scale are based upon the following rates: Charge for energy, 4½d. per unit; capital cost for wiring (without lamps), 10s. per point; capital cost for each service, 20s.; capital cost of the instrument to prevent the use of more lights at a time than are paid for, 15s.; collection charges, 1d. per house per week; annual allowance per lamp for renewals, 2s.

The average number of burning hours per annum has been based on

Digitized by Google

the following:—One point installed, 1,000 hours per annum; two points installed and two lights permitted at a time, 1,300 hours per annum; and so on up to six lights installed and six permitted, 2,000 hours per annum. A chart is also given in the Paper showing how the weekly charges work out on these figures, taking 35 watt lamps. Thus with one light at a time permitted, the weekly charge in winter would be 7d., and in summer 4d. With two lights at a time permitted, and two points wired, the weekly costs would be 8d. and 6d. respectively. With two lights permitted and four points wired, 9d. and 7d. respectively; and so on, until with six lights permitted and six points wired the charges would work out at 12d. and 10d. for winter and summer respectively.

The author next considers the case of 100 consumers divided under these various headings, and shows that the total annual revenue from these 100 consumers would be £184. 0s. 10d.; whilst the cost per annum works out as follows:—

5,330 units at 0·75d.	£16	13	1
Interest and repayment on installation costs	26	5	0
Interest and repayments on services	7	10	0
Interest and repayments on the proportion of plant and mains required (basis maximum demand 5·6 kw.)	21	0	0
Collection expenses	21	13	4
Lamps	16	0	0
Limiting apparatus and terminal costs	15	0	0
Total	£124	1	5

This would leave a net profit of £59. 19s. 5d. Allowing 20 per cent. in extra units for waste, the net profit is reduced to £56. Since drawing out the above scheme the author has come across an article on the proposals of the Fixed Price Light Co.; and, curiously enough, it appears that he has hit upon a very similar scheme that it is the intention of that Company to carry out, with the following differences. The author's scheme provides for the collection of accounts, the supply of lamp renewals, a limiting device, &c., whilst the Company do not collect accounts, supply lamps, or apparently use a limiting device. The price proposed by the Company, viz., 2½d. in the summer and 3½d. in the winter, appears to the author to be too low when dealing with lamps up to, say, two in number. When that number is exceeded the two schemes appear to agree fairly well in price.

In conclusion, the author gives a list of the business obtained during the past three years, which he attributes to the results of commercial activity:—New consumers obtained, 710; equivalent in 30 watt lamps, 74,800; total revenue from sales and wiring (mostly hire purchase), £8,101; total number of arc lamps let out on hire, 283; total horse-power of motors connected to the mains, three years ago, 1,080, at the present time, 2,450; total number of private arcs maintained by the Corporation on consumer's behalf, 338. Annual receipts for motors on hire, £328; annual receipts for the hire of arc lamps, £461; annual receipts on hire purchase account, £1,047; annual receipts for the maintenance of arc lamps, £380; total capital involved, £8,800.

EXHAUST STEAM TURBINES AND CONDENSING PLANT AT McDONALD ROAD STATION.

BY F. A. NEWINGTON.
(Chief Electrical Engineer, Edinburgh).

Summary.—A description is here given of the exhaust steam turbines and condensing plant recently installed at Edinburgh. The most interesting feature is the use of sewage for condensing purposes. The capital cost of the installation and the reduction in the costs per unit generated are tabulated.

The plant described in this Paper consists of exhaust steam turbines connected to direct-current dynamos and condensing apparatus. When McDonald-road Station was designed the intention was to use towers for cooling the circulating water for condensation, but this scheme had to be given up, as it was thought the towers would be unsightly and might cause a nuisance from the steam issuing from the tops of the towers condensing and falling to the ground in the form of rain. Several other methods of getting a sufficient supply of water from a distance were considered, but were found to be prohibitive on account of the cost.

In 1907, the Water of Leith main sewer, which crosses under McDonald-road about 180 yards from the generating station, was brought to our notice, and on investigation, it was found that an average flow of about 750,000 gallons per hour could be obtained. It was therefore decided to utilise the sewer for condensing, and to extend the generating plant by means of exhaust steam turbines.

The sewer is 6 ft. 6 in. inside in diameter, and 22 ft. below the level of the road. A shaft, 26 ft. in diameter, formed of cast iron segments bolted together, was sunk down until the top of the sewer was reached, and a ring of brickwork, of the same diameter as the cast iron shaft, was continued downwards for about another 9 ft., that is, to the bottom of the sewer. The sinking of the cast-iron shaft did not give rise to any difficulties, but the building of the lower brick ring was more troublesome, as during this part of the work there was a great deal of rain, and trouble was caused by the ground slipping in. This ring was built in sections, each a few feet wide. The chief difficulty arose in providing temporary means for carrying the water while the brickwork of the old sewer was being removed. The method adopted was as follows: The top part of the brickwork for about one-third of the circumference was removed; an iron trough formed out of an old Lancashire boiler cut in two longitudinally was then inserted into the brick sewer, the ends projecting 3 ft. or 4 ft. beyond the shaft, both up and down stream, the joints between the sewer and the ends of the trough being made as watertight as possible. The remainder of the sewer inside the shaft was next demolished, the floor of the shaft completed and the temporary trough removed. On account of the heavy rainfall at the time, the sewer was more or less in flood, which increased the difficulties.

Four suction pipes, each 18 in. in diameter, and one discharge pipe, 26 in. in diameter, are laid from the shaft to the station. Straining screens are fixed in the shaft just in front of the suction pit. The end of the discharge pipe in the sewer is water-sealed, so that a syphon action is maintained. Four 14 in. motor-driven centrifugal circulating pumps, each with a capacity of 182,400 gallons per hour, are placed in the basement of the boiler house, each pump having a separate suction pipe from the shaft. The pumps deliver into a common pipe 26 in. in diameter, to which is connected a Bailey & Jackson rotary strainer. From this the circulating water passes through the four condensers back through the rotary strainer, and then is returned to the sewer. The centrifugal pumps are 16 ft. above the average level of the water in the sewer, and the highest point of the pipe system is 30 ft. above the pumps or 46 ft. above the sewer water level, but on account of the pipes forming a closed system, the average head against which the pumps work is 15 lb., that is, 8 lb. suction head and 7 lb. delivery head. As there is a very considerable quantity of air in the water, two air-extracting pumps have been provided: one extracts the air on the suction side of the pumps, the other the air on the delivery side. By this means the syphon action is maintained, and the pressure at the highest point of the pipe system averages about 20 in. of vacuum.

Four surface condensers of the Contraflo type are used, each having a cooling surface of 3,750 sq. ft. The air pumps are of the Edwards type with three throw cranks. The feed water force pump is also driven off the same shaft. At first the air pumps were intended to work on the dry system, but as there was some difficulty in getting the force pumps to work properly, one line of each air pump was altered so that it now delivers the condensed steam to the force pump, the other two lines working dry. Each condenser and air pump will deal with 45,600 lb. of steam per hour with the circulating water entering the condenser at 60°F., and leaving at 90°F., with a guaranteed vacuum of 28 in. with the barometer at 30 in. The ratio of the weight of circulating water to condensed steam being 40 to 1. The air pumps are driven by motors geared through Reynolds chains.

At first the idea of using sewage for condensing does not sound very promising, but at Edinburgh it has proved thoroughly successful. The quantity of water is not as large as one would wish, but is sufficient for a maximum output of about 10,000 kw. Unfortunately about 5 p.m., that is, at the time of the top load in winter, the flow is considerably reduced in consequence of paper works and other industries stopping for the day. The chief troubles are efficient straining and getting rid of the air in the water. The straining arrangements in the shaft consist of three iron grids each 5 ft. high and 3 ft. 6 in. wide, with vertical bars spaced $\frac{3}{8}$ in. apart. These are kept clean by scrapers automatically worked by a small motor. This arrangement answers fairly well, but a certain amount of scraping by hand is necessary at the time of top load. Probably it will be possible to devise some more efficient method of cleaning the grids, and so do away with hand labour. Further straining is done by the Bailey & Jackson rotary strainer which is placed between the pumps and the condensers. This consists of a cast-iron wheel, 9 ft. in diameter, and 12 in. wide with 12 spokes. Between the spokes are fitted grids formed of brass strips built up very much in the form of honeycomb—that is, full of small holes—and about 4 in. deep, the holes being about 0·12 sq. in. in area. The wheel is surrounded by a cast-iron casing which is divided vertically into two portions, which form the delivery and discharge chambers. The vertical partition is wide enough to cover the space between two adjacent spokes of the wheel. The casing has four pipes connected to it, inlet and outlet pipes on the

Digitized by Google

delivery side, and the same on the discharge side. The water enters the strainer by the inlet pipe on the delivery side, passes through half of the grids in the wheel and deposits on them everything that will not pass through the holes. It then leaves by the outlet pipe on the delivery side. After passing through the condensers it re-enters the strainer by the inelt pipe on the discharge side, passes through the other half of the grids, but in an opposite direction, and finally leaves the strainer by the outlet pipe on the discharge side. The wheel is rotated slowly and the discharge water washes off from the grids everything that has been deposited on them on the delivery side, and carries it back to the sewer. The idea of the discharge water cleansing the grids is extremely ingenious. The leakage of water from the inlet chamber to the outlet chamber is considerable. It has only been possible to measure this with one pump in use, the quantity being from 10 per cent. to 12 per cent. of the total. Probably this amount will not be very much increased with four pumps running, but with a limited quantity of water this is rather serious. It also means larger pumps and motors and a larger quantity of electricity used for pumping.

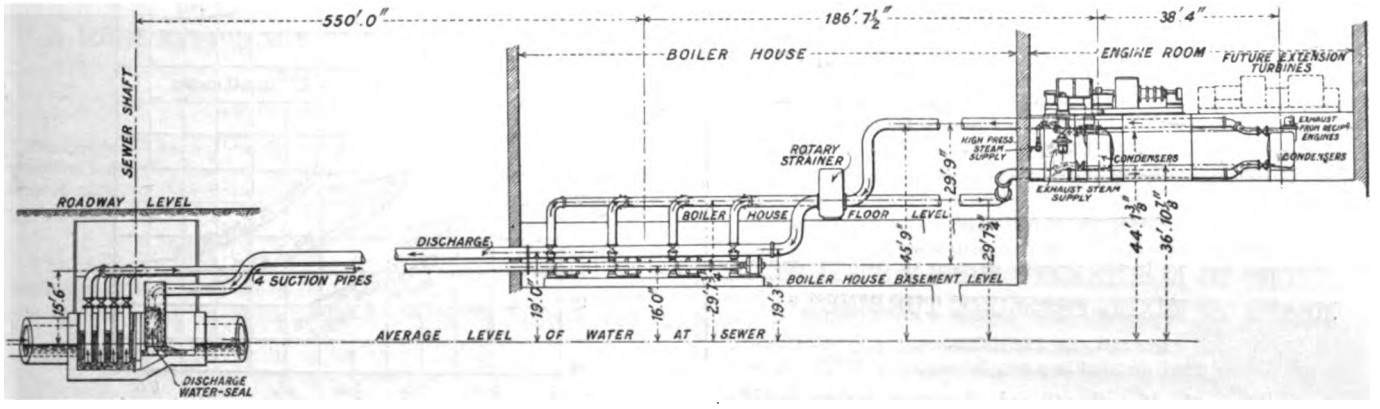
The temperature of the water in the sewer averages about 60°F. in the winter and 70°F. in the summer. As we are prohibited from returning the water to the sewer above 90°F., the range of temperature for condensation is small, and so the quantity of circulating water required per pound of steam condensed is large.

At present only two exhaust steam turbo-generators have been installed, but there is sufficient steam from the reciprocating engines for two more exhaust turbines, and these will be added as soon as the increase in output requires them. The turbines are of the Rateau type running at 1,250 revs. per min. The guaranteed output of each set is 1,200 kw., about 2,200 amperes and 560 volts, with 45,600 lb. of steam per hour at a pressure at the inlet to the turbine not exceeding 14·7 lb. per square inch absolute, and at the exhaust 1·3 lb. absolute, say, 27¼ in. vacuum.

two other condensers. As previously mentioned, two other exhaust steam turbines will be installed over these condensers when required. Automatic atmospheric valves are placed in the exhaust pipes between the reciprocating engines and the turbines. The conditions under which these valves have to work are very severe. They are balanced to open at about 3 lb. above atmospheric pressure, so they are always nearly in equilibrium, consequently they are very apt to chatter and so damage the faces. The valves first supplied were quite unsuitable. Those now in use, however, are working very well, the improvement being due to very strong construction, careful fitting of all moving parts to prevent all backlash, and the use of a special dash pot which admits air freely on the upward movement of the valve, but by means of a non-return valve, only allows it to escape very slowly when the valve is closing.

Oil separators of the Blake type are placed in the exhaust pipes between the reciprocating engines and the turbines which extract the greater part of the oil. The feed water is further treated by the Davis Perrett electrical process for freeing it from oil. The water from the air pump discharge passes into wooden tanks in which are a number of iron plates spaced about 2 in. apart. A current of electricity is passed through these tanks with the object of precipitating finely divided oxide of iron. The small globules of oil adhere to the oxide of iron, and so are easily separated from the water. The treated oily water then passes into filters containing gravel and sand which retain the oil. Automatic arrangements are provided for flushing the filters to clean the sand. The quantity of electricity used in the filter is 1 unit for every 1,000 gallons of water treated. The makers guarantee that the filtered water will not contain more than $\frac{1}{10}$ grain of oil per gallon. This is such a minute quantity that it is not easy to measure, but after 12 months' steaming the boilers show hardly a trace of oil.

The diagram shows the general arrangement of the shaft, pipework, condensers, turbines and other plant.



DIAGRAMMATIC ARRANGEMENT OF CONDENSING PLANT AT THE ELECTRICITY SUPPLY STATION, McDONALD-ROAD, EDINBURGH.

This output is easily obtained in everyday work. This means that the exhaust steam from two of the 780 kw. reciprocating sets is sufficient to give an output of 1,200 kw. from one of the turbo-generators. Live steam is connected to each turbine through a reducing valve in case the supply of exhaust steam at any time should not be sufficient. These machines will give 25 per cent. overload for a short period. The rotor of each turbine has 11 wheels with 265 blades on each wheel. The clearance between moving and stationary parts is considerable, and there has not been any indication of stripping. Besides the usual governor there is an emergency governor which comes into action if the speed exceeds 10 per cent. of the ordinary running speed, and also acts if the pressure of the lubricating oil falls.

The dynamos were built by Brown, Boveri & Co. They are four-pole machines, and are separately excited by a small dynamo at the end of the shaft. Copper brushes are in use on one machine. The commutator of the other machine has been altered to give increased ventilation, and carbon brushes are fitted. There was some little trouble at first with commutation, but this has been overcome, and both machines are now running well, especially the one fitted with carbon brushes. This commutator keeps very cool, being only 42°F. above the temperature of the air after a six hours' full load run. Each commutator has 100 bars giving a pressure of about 22 volts per bar. At first there was a considerable amount of vibration on these machines, but this was caused by the turbine and dynamo shafts not being quite in line, and by the type of flexible coupling employed. Since one machine has been accurately lined and another type of coupling fitted, the vibration on this has entirely ceased.

The exhaust steam pipes are arranged so that the steam from the reciprocating sets can pass either to the exhaust turbines or direct to

There is not the least difficulty in running the turbo-generators in parallel with the other dynamos. The old dynamos are shunt wound, and the turbo-generators compound wound. The whole regulation is done by the switchboard attendant by means of the shunt resistances. The only point to be careful about is to see that steam is not escaping past the atmospheric valves, which would mean waste. In order to prevent this, indicators have been fitted just above the atmospheric valves, and directly any steam passes the valve an electric circuit is closed which rings a bell on the switchboard. The switchboard attendant then puts more load on to the turbine, and so reduces the pressure of the steam in the exhaust pipe.

Cost of Plant.—The condensing plant is sufficient to deal with the steam from reciprocating and exhaust turbines of 11,000 kw. The capital cost was as follows:—

	£	Per kw. £
Sewer shaft with four 18 in. suction and one 26 in. discharge pipe in roadway	5,600	0·5
Circulating water exhaust steam pipework inside the station and oil-extracting plant	6,000	0·5
Rotary water strainer	2,000	0·2
Four condensers circulating and air pumps	11,000	1·0
	£24,600	2·2
Two 1,200 kw. turbo generators with switchboard	£13,800	5·7

The economy caused by the exhaust steam turbines and condensing plant is shown by the following figures, which are for similar periods in 1908 when only reciprocating engines were used without condensation, and in 1910 with exhaust steam turbines and condensation. In 1908 the price of coal was considerably lower—10d. a ton—than in

Digitized by Google

1910, but for the purpose of comparison the 1910 price has been taken for both periods. In the costs per unit generated for the 1910 figures, the units used by the condensing plant have been deducted. As only three of the boilers are fitted with superheaters the amount of superheat is quite small :—

	1908.	1910.
Duration of test	3 weeks	3 weeks
Date	Jan. 16th to Feb. 6th	Jan. 20th to Feb. 9th
Units generated	715,491	888,644
Units used by condensing plant	—	43,045=4·8%
	715,491	845,599
Load factor	22·8%	25·1%
Plant factor	89·6%	76·9%
Lb. of water per unit generated	39.0 lb.	22·2 lb.
Lb. of water evaporated per lb. of coal	6·67 lb.	6·6 lb.
Lb. of coal per unit generated	5·85 lb.	3·9 lb.
Maximum output	6,227 kw.	7,021 kw.

Costs per Unit Generated.			Saving.
Fuel	0·251d.	0·167d.	33·4%
Oils and stores	0·009d.	0·004d.	50·0%
Water	0·027d.	0·006d.	78·0%
Salaries and wages	0·054d.	0·047d.	—
Repairs (estimated)	0·057d.	0·057d.	—
	0·398d.	0·281d.	30·0%

At present at the time of top load in the winter months three or four reciprocating engines are exhausting direct to the condensers, so the economy will be increased when the other two turbines are installed.

Some engineers seem to think that exhaust steam turbines are only a passing fashion and will disappear in a few years, but in stations with existing reciprocating engines, either exhaust steam or mixed pressure turbines seem the most suitable for extensions, as the combination of reciprocating engine and turbine is as economical as high-pressure turbines, and obviates all necessity of scrapping the old sets until these are worn out. As shown by the figures above giving the capital costs, the price of the sewer shaft and pipework in the roadway comes to £0·5 per kw. This is considerably less than cooling towers would have cost. In places where a river or other sufficient supply of water is not available for condensation, a main sewer, if near the generating station, is well worth consideration.

EXTENSIONS TO ELECTRICITY SUPPLY STATIONS BY MEANS OF MIXED PRESSURE TURBINES.*

BY ASHTON BREMNER.
(Chief Electrical Engineer, Burslem.)

Summary.—The author describes the mixed pressure turbine installed at Burslem, and gives particulars of the saving in works costs thereby obtained. He also mentions the saving obtained in other installations of mixed pressure turbines, which latter he considers are an economical method of extending existing supply stations.

One of the chief reasons why many stations are financial failures is because they are overweighted by capital charges. Burslem is situated in an industrial area where, for the most part, only motors of small power are required and steam for heating and drying is a necessity. Here, if electricity is to compete at all with other motive powers, the scale of charges must be very low indeed ; consequently more than ordinary care was taken that the plant at first installed was suitable to the probable demand and easily extended.

Starting in 1905 with one 100 kw. and one 200 kw. Howden-Dick, Kerr sets, a similar set of 350 kw. capacity was installed in 1907. Further extensions becoming necessary, the writer early in 1908 advised that a 600 kw. Belliss-Siemens mixed pressure turbo-generator be installed, the plant being so designed that it could be used either as auxiliary power on exhaust steam or as stand-by plant on live steam. This type of plant seemed to offer the best solution of the problem because, as the original sets were run non-condensing the whole of the exhaust steam could be utilised in the turbine to produce additional power without increasing the cost of coal and water. A study of the entropy diagram will show that the turbine develops approximately the same power as the sets which supply it with steam.

The general lay-out of the mixed pressure turbine at Burslem is shown in a diagram accompanying the Paper. The reciprocating set can be run either non-condensing, condensing or in connection with the turbine, or the turbine can be run as a separate unit.

* Abstract.

The results of the official test of the turbine carried out at the makers' works are as follows, the plant running at 1,850 revs. per min. :—

No. of H.P. nozzles open.	Kw.	Steam per kw.-hr.	—	Vacuum, inches.
		lb.

Fig. 1 gives the result of tests of the steam consumption per kilowatt-hour under different conditions and varying loads. As a guide to the power obtainable from the exhaust steam of reciprocating engines the following figures given by a firm of turbine builders may

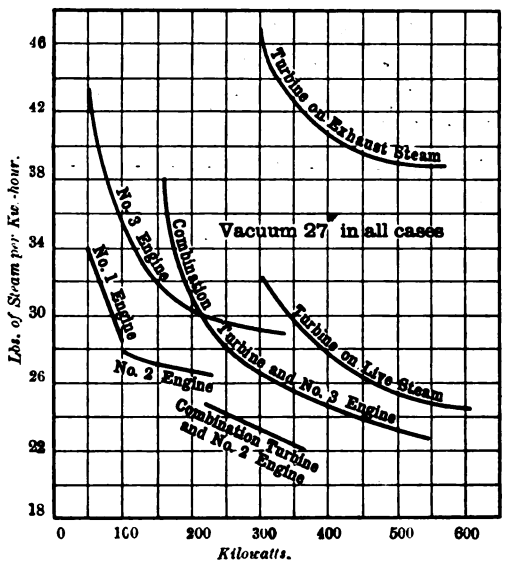

Fig. 1.

be mentioned. With a 500 kw. compound engine working non-condensing on saturated steam, 375 kw. additional power can be obtained from the turbine ; or, if superheated steam is being used, the power obtainable is 320 kw., in each case less, say, 5 per cent. required to

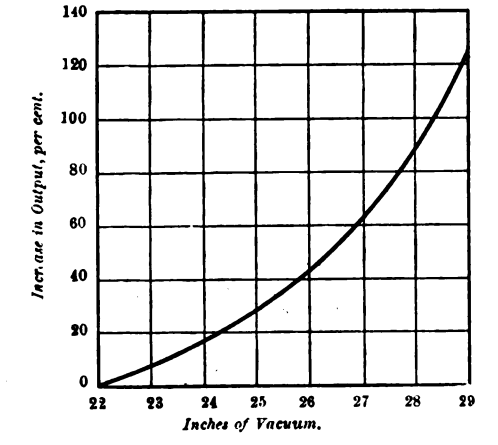

Fig. 2.

drive the condensing plant. The author also gives the results of the working economies of the power house plant of a large engine builder's works. The figures show a saving per kilowatt-hour, by using a mixed pressure turbine, compared with the engine alone, of

Digitized by Google

18·45 per cent. on a one hour's test (steam consumption 17·7 lb. and 21·7 lb. respectively), and 26 per cent. (fuel consumption 3·93 lb. and 5·31 lb. per kilowatt-hour respectively) on a test extending over three months under average station conditions. The power house was equipped with one 300 kw. and one 400 kw. triple-expansion engine running with a steam pressure of 160 lb. and vacuum of 26 in., the steam being superheated from 50°F. to 150°F. At the beginning of 1908 an exhaust pressure turbine was installed which, running on the exhaust of one of the engines, was able to cope with the maximum load of the station and at the same time to give economical running on lighter loads. The fuel is slack of poor calorific value.

A turbine of the Westinghouse-Parsons type of 368 kw. capacity installed at the Gloucester Railway Carriage & Wagon Co.'s works is fitted with high and low-pressure steam chests, the latter capable of dealing with 9,000 lb. of exhaust steam per hour, and from which 210 kw. is obtained, the rest of the load being carried on high-pressure steam. In this turbine the governing is effected by giving the low-pressure governor valve a lead over the high pressure, so that the full quantity of exhaust steam is always used before high-pressure steam is admitted.

After giving a brief description of the Belliss-Morcom mixed pressure turbine installed at Burslem, the following figures of works costs per unit generated are tabulated to show the gain (32 per cent.) due to installing the turbine. The calorific value of the coal = 12,700 B.Th.U. per pound, and its cost per ton 7s. 3d. into bunkers.

	Reciprocating sets only. April, 1909.	Combination of turbine and reciprocating sets. April, 1910.

Water	0·071d.	0·028d.
	0 315d.	0·212d.

Fig. 2 shows the increase in output from exhaust turbine with increased vacuum.

A HIGH EFFICIENCY REFLECTOR FOR STREET LIGHTING.*

BY CLAYTON H. SHARP.

Summary.—The author describes a new form of reflector, specially adapted for street lighting by incandescent lamps and designed to give a more uniform illumination. The results of tests on typical installations are given.

The problem of the satisfactory illumination of public streets and highways is one which we shall always have with us. The extent of the streets requiring illumination is practically limitless and the

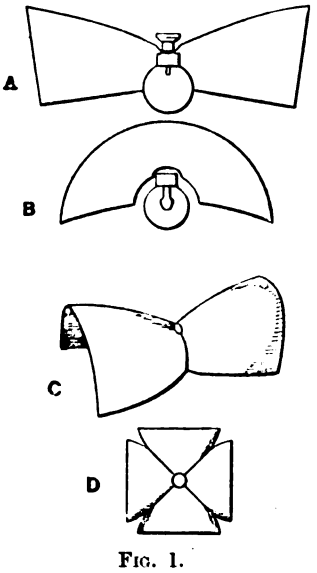

Fig. 1.

demand for more light is unceasing. In view of this undoubted demand for higher degrees of illumination and for continuous extensions of lighting systems to streets now unlighted, the most important question which arises is that of economy. An economical street lighting system can be realised in any particular case by the selection of such illuminants as shall be most economical, by the proper location of these illuminants, and finally by the most effective utilisation of the luminous flux available.

Great progress has been made in the last 10 or 12 years in the production of economical illuminants for street lighting. The introduction of high-pressure mantle burners, of tungsten lamps and of flaming arc lamps has been of great importance to the art of economical street illumination. In many respects the most significant and important advance has been in the production of the tungsten lamp, the advent of which opens up a field in street lighting which was formerly entirely inaccessible to the electric supply company and which has enormous possibilities.

In the production of devices aiding in the proper distribution of luminous flux for the economical lighting of streets, relatively little progress has been made. In interior illumination, this is not so. Within the last few years the greatest attention has been given to the question of proper shades and reflectors so that to-day almost any requirement can be met by appliances actually on the market. The problem of the design of reflectors and globes for street lighting is

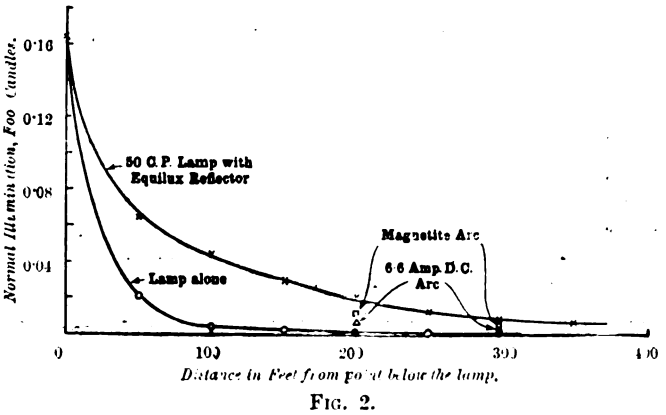

Fig. 2.

quite different from that of interior illumination, although this difference has seldom been recognised. For the illumination of interiors, it is desirable that a certain flux of light reach the ceiling of the room. The ceiling must be illuminated, and sends back a proportion of such flux to participate in the useful illumination of the room. In the case of street illumination, all flux leaving the fixture above the horizontal plane is absolutely wasted. Therefore, a street lighting reflector should direct as nearly as possible all luminous flux in directions below the horizontal. Furthermore, in interior illumination, the distribution of flux about the vertical axis of the lamp with its reflector, may usually, without detriment to efficiency, be symmetrical. In the illumination of streets, the case is quite different. The crosswise dimension of a street may be taken as of negligible importance as compared with the lengthwise dimension. Therefore, if the distribution of flux be symmetrical, an undue proportion of the flux is directed towards the sides of the street. The distribution must be unsymmetrical, a far greater proportion of flux being directed lengthwise of the street than crosswise of the street.

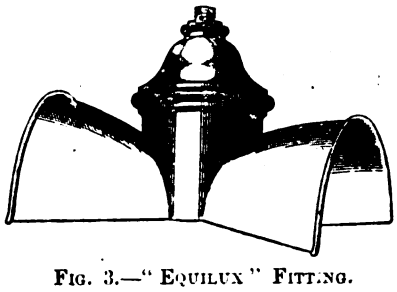

Fig. 3.—"Equilux" Fitting.

The requirement of street illumination is that the roadway and objects in the same shall be illuminated to a degree which shall at every point exceed a certain minimum value. What results from the ordinary arrangement of lamp alone or lamp with symmetrical reflector is that, in the vicinity of the lamp, the street is excellently illuminated, but this illumination falls off rapidly with the distance, so that at a point midway between lamps it has a relatively very low value. At the same time each lamp distributes crosswise of the street as much light as lengthwise, and only a small proportion of this light is effective in lighting the street itself, the major part being wasted on the roadside. Thus the ordinary system of street illumination is very inefficient from two causes, first in that only a small percentage of the total luminous flux is incident on the surface to be

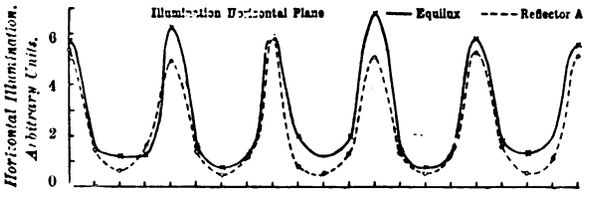
* Abstract of a Paper read before the New York Section of the Illuminating Engineering Society.

Digitized by Google

illuminated, and second in that the distribution of the flux so incident is such that the illumination in the immediate vicinity of the lamps is unduly high, while midway between lamps the minimum illumination, which is by far the most important factor to be considered, is far too low.

The reflector and lighting fixture here described represent the results of an endeavour to obviate these disadvantages of the ordinary system of street lighting, and thereby to obtain a more economical and more uniform illumination. The problem was to collect the luminous flux ordinarily wasted in the upper hemisphere and toward the sides of the street and to re-direct that flux so that it would be incident on those parts of the street where it was most needed—namely, in the region midway between the lamps. This result should be accomplished without interfering with the natural illumination on the street surface from the lamp directly, so that in case the device became inoperative or operated badly, as by the accumulation of dirt, the illumination would at least not be any worse than if the device were absent entirely.

It is clear that stray light could be collected and redirected so as to illuminate the regions midway between lamps by the use of a parabolic mirror with the lamp at the focus. But this arrangement

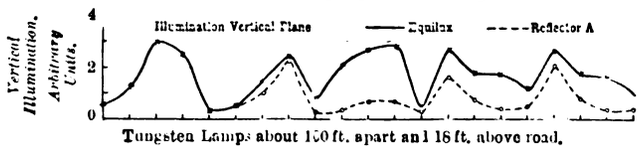


Tungsten Lamps about 100 ft. apart and 18 ft. above road.

FIG. 4.

would cut off the necessary light near the lamp-post and hence would be impracticable. This difficulty could be met by cutting away the lower portion of the reflector. But this arrangement is not yet all that is desired because it directs the light in only one direction instead of two directions 180 deg. apart as required. This condition may also be met if the parabolic reflector is cut through vertically in the focal plane and a similar reflector also with its lower half cut away is placed back to back with the first. This results in a structure which does not obstruct the natural illumination of regions near the lamp and which by redirecting light otherwise wasted builds up the illumination in the dark parts of the street. A cross-sectional view of such a reflector is given in Fig. 1 A. It will be seen that the semi-paraboloids are inclined to each other so that the two reflected beams will fall on the street surface at the required distance from the lamp-post. Fig. 1 B shows an end view of the reflector and lamp, and Fig. 1 C gives a perspective view of the exterior.

An objection may be made to this arrangement on the grounds that a parabolic mirror throws a nearly parallel beam of light. Consequently the effect of the proposed arrangement would be to



Tungsten Lamps about 150 ft. apart and 16 ft. above road.

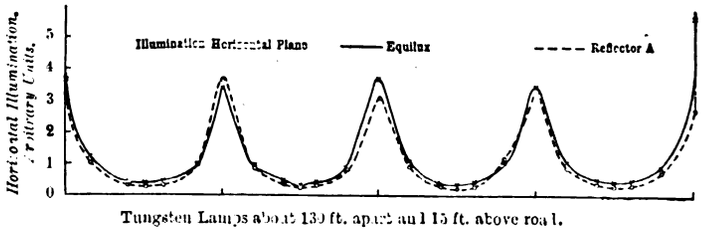
FIG. 5.

illuminate only a small area of the street by the rays coming from the mirror; that is, at a point midway between the lamps there would be a little bright patch which would amount to nothing as far as the general illumination goes, while the surrounding portions of the street would be left in darkness as before. This objection would be a very valid one provided we had a very small source of light in the focus of the mirror. Then the effect would be that of a searchlight beam. What we actually have in practice with the tungsten lamp is quite an extended source. The result of this is that the beam of light is a divergent one, and at the distance where it is effective it covers a considerable area. The angle of divergence of a beam of this character is equal to the angle which is subtended at the mirror by the source of light. It is found in practice that this angle is sufficient to cause reflected rays to cover all the area of the street surface which is required.

The idea which is developed above of using two semi-parabolic mirrors pointing in opposite directions may evidently be extended to include three or four or more. For example, at the intersection of streets, a reflector would be used which has the form shown in Fig. 1 D. It is clear that this reflector would not be so effective in any one direction as is the two-direction reflector, because the luminous flux is divided by four rather than by two. Still the gain resulting from the use of this reflector would undoubtedly be very considerable. The most effective form being the two-reflector form, and there being less waste light with such reflectors as are commonly in use in the case of lamps placed at the intersection of two streets than there is in the case of lamps placed in the middle of a block, the two-direction reflector is the one which has been given the chief attention up to the present time.

The first reflector which I had made was constructed of zinc. The zinc was spun into the form of a paraboloid of revolution cut through the focal plane. This paraboloid was afterwards cut in two lengthwise and the halves were mounted in the way shown in Fig. 1. The interior of the paraboloid was brightly burnished and made a very good reflecting surface. In the proper position in this reflector a 50 c.p. Gem lamp was mounted, and the fixture was raised to a height of approximately 15 ft. above the street. The normal illumination produced at different distances by the reflector was then measured by a portable photometer and was compared with the illumination which would have been produced by the lamp alone. The latter illumination, however, was, excepting quite close to the lamp-post, too small to be measured with any degree of accuracy. This test was carried on in a quiet residence street which was very badly illuminated by series incandescent lamps placed some 300 ft. apart. The normal illumination values obtained in this test are given in Fig. 2. Points are also plotted to show the standard values adopted for the magnetite arc and for the 6·6 ampere direct-current enclosed arc, as adopted by the National Electric Light Association. It will be seen that both of these values are considerably exceeded by the 50 c.p. incandescent lamp with reflector.

The results of this test were so encouraging that the work was taken up of developing a commercial form of street lighting fixture embodying this reflector. In this part of the work, I have enjoyed the invaluable co-operation of Mr. S. G. Rhodes, engineer of the street lighting department of the New York Edison Co., and of his assistants. To the efforts of Mr. Rhodes is largely due the successful form in which the lighting fixture now is found. The typical form



Tungsten Lamps about 130 ft. apart and 15 ft. above road.

FIG. 6.

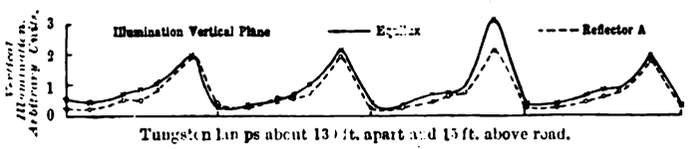
of this fixture for incandescent lamps, which is patented, is shown in Fig. 3. To this fixture I have given the name "Equilux," which is descriptive of its purpose.

In the fixtures so far made the reflectors have been enamelled white on the interior. This enamel finish has the great advantage of being permanent and easy to clean. It has not, however, the very high reflecting power of a planished metal reflector, and consequently is considerably less efficient in increasing the illumination. The planished metal reflector is open to the objection that the light from it is very intense and that the glare is somewhat blinding. This is simply another way of saying that it is delivering a very powerful beam of light and that it is very efficient in doing the work for which it is intended. Any device whereby the glare is diminished at the same time diminishes the efficiency. The white enamelled reflector gives less glare; it also gives less powerful directed beams, although the total light from it is probably nearly as great. It is necessary, therefore, in choosing reflectors of this kind to weigh the advantages of lack of glare and ease of maintenance of the white enamelled reflector against the very high efficiency of the polished metal type.

The results of illumination tests made by the Electrical Testing Laboratories on two installations of these reflectors are given in Figs. 4 to 7. In the case of the first installation (Figs. 4 and 5) there were five "Equilux" reflectors with series tungsten lamps, and on the same street five reflectors of the flat round type with flutings, such as are often used, the lamps being similar. The spacing of the poles was about 100 ft. and the height of the lamps from the ground about 18 ft. In the second installation (Figs. 6 and 7), practically a country road, the spacing of the poles was 130 ft. and the height of the lamps from the ground 15 ft. With this installation, also, illumination tests were made under comparable conditions using the "Equilux" reflector and a standard round reflector. It will be seen that the "Equilux" reflector was effective in increasing the illumination in those parts of the street where it is naturally deficient, and that the percentage increase was quite a notable one in those regions.

Digitized by Google

An unexpected result was that the illumination directly below each lamp was also somewhat higher, indicating the large amount of diffused reflection from the white enamelled surface. This diffused reflection is a cause of a loss of efficiency of the "Equilux" reflector as far as its own particular function is concerned of increasing the illumination midway between the lamps. It is upon this feature, however, that the absence of glare from the reflector depends. The second installation tested showed a result which was considerably inferior to that of the first installation. The reason for this deficiency was to be found in the character of the enamel on the "Equilux" reflectors, and being simply an incident of the manufacture, should not be taken as detracting from the possibilities of the type. Even with the inferior enamel the increase in illumination in the regions where the light is most needed amounted to something like 50 per cent. It is safe to say that with the "Equilux" reflector a substantial gain of 100 per cent. in the effective illumination can be obtained with the enamel type; whereas with the polished metal type, there should be no difficulty in increasing the effective illumination 200 or 300 per cent.



Tungsten lamps about 13 ft. apart and 15 ft. above road.

FIG. 7.

The polished metal type is of particular applicability to the illumination of country highways where for reasons of economy it is necessary that lights be placed at very considerable distances from each other. By the use of the polished metal "Equilux" reflector and such incandescent lamps as are ordinarily used for the purpose at the present time, a very acceptable highway illumination can be obtained with but 10 lamps to the mile. As has been said, the glare from this polished metal reflector is objectionable. However, it should be distinctly understood that this glare is not as great as is the glare from an arc lamp with clear globe, whereas the illumination produced with an 80 watt tungsten lamp with a polished metal reflector is at least comparable with that obtained with the ordinary type of arc lamp consuming four of five times the energy. Moreover, where trees do not interfere too greatly, tungsten lamps with polished "Equilux" reflectors can be mounted at such an elevation above the road surface that the light does not fall too directly into

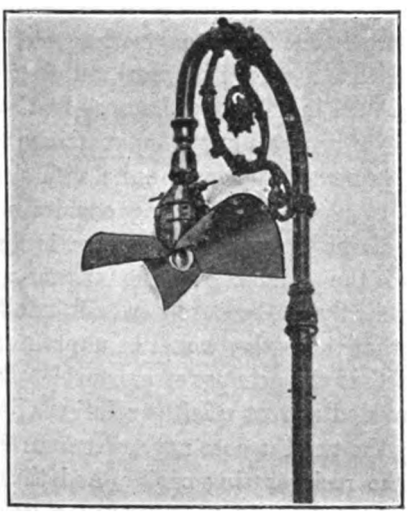


FIG. 8.—SUGGESTED STREET LIGHTING FITTING.

the eyes of pedestrians. This would require simply a reflector with a greater angle between the two halves.

A number of street lighting fixtures for incandescent lamps in which the reflector has been incorporated are illustrated in the Paper. One form is shown in Fig. 8 herewith. The appearance of these fixtures is undoubtedly somewhat odd, but the author says that one soon grows accustomed to their strangeness and they are by no means displeasing. The applicability of this type of reflector to other illuminants should also not be lost sight of. It can be applied to mantle burners and to arc lamps, though probably the effectiveness of it in the case of these sources of light would not be so great as in the case of incandescent lamps. There are also other fields of application outside of street lighting—for example, long corridors, as in a hotel.

FARADAY SOCIETY.

At the meeting held on May 31st, in the rooms of the Chemical Society, Burlington House, Mr. W. M. Morrison in the chair, Mr. J. W. HINCHLEY read a Paper entitled

"Some Practical Experience of the Sherardising Process."

The sherardising process (a method of dry galvanising in which iron or steel articles are coated with zinc by being heated in closed receptacles with zinc dust) is of great interest on account of the fact that no adequate scientific explanation has appeared. It was discovered by Mr. Sherard Cowper-Coles about eight years ago, and has been worked commercially for the past seven years. The general theory given by the inventor that the zinc vaporises from the zinc dust and is condensed on the particles is in complete antagonism with the commercial practice of the process. The successful conduct of the process depends mainly on the percentage of metallic zinc in the zinc dust being kept at a suitable figure, while the limits of temperature and time required are comparatively wide. The best mixture of zinc dust for jobbing work contains about 18 per cent. of metallic zinc.

Sherardising begins at a temperature just above that required to produce a film of magnetic oxide of iron on the article. In all cases the deposit of zinc contains iron, and the conclusion is drawn that the interaction of the film of magnetic oxide of iron and the zinc dust determines the deposition of zinc. No deposit can be obtained from the vapour of zinc at any sherardising temperature—*i.e.*, at any temperature below the melting point of zinc. At temperatures higher than this the deposit is not in any way comparable with a sherardised coating, and is useless. At 250°C., a temperature usually not much exceeded in best work, the vapour tension of zinc is not likely to be greater than that of mercury at 0°C.—*i.e.*, $\frac{1}{2000}$ mm. mercury—a pressure quite incapable of depositing 1 oz. of zinc per square foot of surface in less than an hour.

The process is essentially a contact process; a film of magnetic oxide of iron is first formed and then reduced to metallic iron by contact with the metallic zinc in the zinc dust, forming a film of solid solution of iron in zinc as closely adherent to the iron as the original magnetic oxide film. If the amount of metallic zinc in the zinc dust be insufficient, a black film of reduced iron is formed. The deposit resists corrosive agents much better than pure zinc on account of the P.D. between it and metallic iron being less than between pure zinc and iron. As a protective agent against atmospheric corrosion the deposit is most remarkable. After the slight yellowish powder which is first formed has been washed off by the rain the surface gradually becomes black and practically permanent. Chain blocks treated by the process have been in use in the open air for seven years, and are now free from rust and, apart from the result of daily wear, as good as new. In England a dearth of enterprise on the part of manufacturers has led to the existence of jobbing factories only. In America many firms making specialities have adopted the process in their own factories, and the daily output is greater there than the quarterly output in England.

The following Papers were also read: "Thermic Reactions in Vacuo," by Mr. F. E. Weston and Mr. H. R. Ellis; "Relations between Critical Temperature, Boiling-point and Thermal Expansion of Phosphorus Pentachloride," by Mr. E. B. R. Prideaux; and "Note on the Composition of Eutectic Mixtures," by Dr. Cecil H. Desch.

Mr. C. V. Biggs and Mr. W. Pollard Digby also exhibited and gave a short demonstration of: (1) Apparatus for the Rapid Determination of the Resistance of Liquids; (2) Apparatus for the Determination of the Specific Resistance of Oil. The former apparatus consists of a megger furnished with a scale reading reciprocal megohms, used in conjunction with a glass U-tube to contain the liquid under examination. Polarisation is minimised by the use of annular platinum electrodes and by having the tube very long compared with its sectional area, the voltage employed being about 250. A reading is obtained in a few seconds. The apparatus is particularly suitable for checking the purity of the water supply for boilers, for controlling the softening of hard water and for similar engineering purposes, as well as for scientific investigations.

The apparatus for measuring the resistance of oil consists of two parallel metal discs of 100 sq. cm. area, insulated from one another. These are separated by a micrometer head to a distance of about 100 mils, immersed in the oil, and then connected to a megger and a reading taken. The mean specific resistance is calculated as the mean of a series of readings.

The Rates for Subscription to "THE ELECTRICIAN" are as under —

	Year.	Half-Year.	Quarter.	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Canada	28s. 3d.	14s. 6d.	7s. 6d.	
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.	

New volumes of "THE ELECTRICIAN" commence in April and October.

(This charge includes all Supplements.)

Vols. I. to LXIV. can now be supplied. Price on application.

"THE ELECTRICIAN" SERIES OF STANDARD ELECTRICAL BOOKS

can be obtained of all Booksellers at Home, in the Colonies, and Abroad.

THE "ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1882. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Dec. 31st in each year for the next following edition) 8s. 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s.; Europe, 2s.; U.S.A., 3s. 6d.; other countries, 2s. 6d. *Digest of Contents sent free on application.*

THE "C.T." GEOGRAPHICAL DIRECTORY OF THE U.K. (Electrical Section). Subscription 5s., post free.

"THE ELECTRICIAN" PRIMERS (81 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three separate Vols. now ready.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS. By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [abroad 13s.

VOL. I.—Price 12s. 6d. post free, abroad 13s. VOL. II.—Price 12s. 6d. post free, abroad 13s.

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A. Fleming. Vol. I., 12s. 6d. nett, Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett; or bound in strong cloth, 15s. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

A SMALLER SET of only 40 Forms, bound strong cloth. Price 7s. 6d. nett.

CENTENARY OF THE ELECTRIC CURRENT—1799-1899. By Prof. J. A. Fleming, F.R.S. Price 1s.; strong cloth 2s. 6d.

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstroin. Illustrated. 3s. 6d. nett.

RADIO-ACTIVITY: AN ELEMENTARY TREATISE, FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Geipel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S. Price 10s. 6d.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By G. M. Baines. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d.

"THE ELECTRICIAN" WIREMAN'S POCKET BOOK. Edited by F. C. Raphael. Price 5s. nett.

"THE ELECTRICIAN" HANDY WIRE TABLES FOR THE POCKET. By P. B. Down, Wh.Ex., A.M.I.Mech.E. Price 2s. 6d. nett.

THE RATING OF ELECTRIC LIGHTING, ELECTRIC TRAMWAY, AND SIMILAR UNDERTAKINGS. By W. C. Bond, M.I.E.E. Price 2s. 6d. nett.

DRUM ARMATURE WINDING AND COMMUTATORS. By F. M. Weymouth. 7s. 6d.

PRIMARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By W. R. Cooper. Price 10s. 6d. nett.

SECONDARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By E. J. Wade. Price 10s. 6d. nett.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. Price 1s. 6d.

THE LOCALISATION OF FAULTS IN ELECTRIC LIGHT CABLES. By F. C. Raphael. 7s. 6d.

THE STEAM-ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont, M.I.C.E., M.I.M.E., &c. Price 6s. nett.

THE ELECTRIC ARC. By Mrs. Ayrton, M.I.E.E. Price 12s. 6d.

TRAMWAY TRACTIVE EFFORT AND POWER DIAGRAM. By Arnold G. Hansard, B.A., A.M.I.E.E. Price 4s. 6d. nett; in Tube, 5s.

THE BRITISH POST OFFICE TELEPHONE SERVICE. Fully illustrated.. Price 3s. 6d. nett.

INTERNATIONAL TELEGRAPH CONVENTION AND SERVICE REGULATIONS. Price 6s. nett. (LISBON REVISION, 1908.)

BOILER FEED WATER. By F. W. Anderson. Price 6s. nett.

(PRELIMINARY) WIRELESS TELEGRAPH CONFERENCE (BERLIN, 1903), PROCEEDINGS AT. Price 8s. 6d. nett.

INTERNATIONAL WIRELESS TELEGRAPH CONVENTION AND SERVICE REGULATIONS (BERLIN, 1906). With complete report of Proceedings. Price 21s. nett.

THE CLASSIFICATION OF ALTERNATE-CURRENT MOTORS. By V. A. A. Fynn, M.I.E.E. Price 3s. nett.

ELECTRIC CRANES AND HOISTS. By H. H. Broughton. *In Preparation.*

PRACTICAL TELEPHONY. By W. Aitken, M.I.E.E. *In Preparation.*

ELECTRIC MAINS AND DISTRIBUTING SYSTEMS. By J. R. Dick, B.Sc., and F. Fernie, A.M.Inst.C.E. *In Preparation.*

THE PRACTICAL WIRELESS SLIDE RULE. By Dr. H. R. Belcher-Hickman. Price 2s. 6d. nett. *Nearly Ready.*

THE MECHANICAL DESIGN AND CONSTRUCTION OF GENERATORS. By R. Livingstone. *In Preparation.*

LIGHT, RADIATION AND ILLUMINATION. From the German of Paul Högner, by Justus Eck. *In Preparation.*

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fiftieth issue of the Supplement will be published (Gratis) with the number of "THE ELECTRICIAN" for June 24.

The "INDUSTRIAL SUPPLEMENT" is a comprehensive record of developments in Electrical Plant, Machinery, Apparatus, Accessories, Sundries and Materials, and of their proved suitability for various Industrial purposes.

The "INDUSTRIAL SUPPLEMENT" is holed for filing or hanging, and filing covers can be supplied for holding 6 or 12 issues.

THE PROGRESS OF THE EXHAUST STEAM TURBINE.

In the race for a profitable existence the keynote of the electricity undertaking is "efficiency"—the obtaining of more and more energy from a given amount of coal. The problem is largely one for the engine designer, though it must be admitted that a very great deal still depends upon the methods pursued in the boiler house. In the engine room the chief line of progress but a few years ago was the use of high steam pressures and large units with a certain superheat. But even with condensing engines a considerable proportion of the energy in the steam is finally rejected unused into the condenser. The expansion cannot be carried sufficiently far, because it would entail cylinders of such a size that the outlay would be unprofitable.

It is here that the exhaust steam turbine has stepped in and has provided a most efficient solution of the difficulty. Fortunately the turbine does not suffer from the same limitations as the reciprocating engine, and thus there is no difficulty in dealing with a large volume of low temperature steam, and recovering valuable work from a waste product. Instead of pressure upon a piston we deal with the momentum of the steam, and this is a quantity that depends very much less upon the pressure of delivery. Thus the exhaust steam turbine becomes not merely commercially practicable, but quite efficient.

Some prominence was given to the subject last year by Sir ALEXANDER KENNEDY in a report in which he recommended the use of exhaust steam turbines for the Dewar-place generating station of the Edinburgh electricity undertaking. This station was working non-condensing, and the

Digitized by Google

output per annum was 7,500,000 units. The average cost of generation for the whole undertaking with an output of 17,600,000 units was 1·18d. per unit. By running the station condensing and putting in exhaust steam turbines it was estimated that a further output of 3,500,000 units per annum would be obtained at a cost of 0·45d. per unit. Thus a saving of £10,000 per annum appeared to be possible.

Further attention is now drawn to the subject by Mr. F. A. NEWINGTON'S Paper read at the Convention of the Incorporated Municipal Electrical Association, in which details are given of the results obtained at the McDonald-road station of the Edinburgh Corporation. Here again the station was formerly non-condensing, and it was intended to erect cooling towers for the condensing water; but this idea was given up as it was thought that such towers would be unsightly and might cause a nuisance. Condensing water has now been obtained from the main sewer, and a very interesting installation is the result. Needless to say sewage does not provide an ideal water for condensing purposes, and more than usual precautions have had to be adopted in order to free the water from refuse. In addition to this novel method of condensing, two exhaust steam turbines, each of 1,200 kw., have been installed. It is found that the exhaust steam from two of the existing 780 kw. sets is sufficient for one of the 1,200 kw. turbo-generator sets. For a period of three weeks, with a small amount of superheat, it was found that in 1908 the water used per unit generated amounted to 39 lb. and the coal per unit generated to 5·85 lb.; whereas in 1910, under the new conditions, the number of pounds of water per unit generated fell to 22·2 and the pounds of coal per unit generated to 3·9. The number of pounds of water evaporated per pound of coal was roughly the same in both cases, and the load factor had risen from 22·8 per cent. in 1908 to 25·1 per cent. in 1910. A saving of 33·4 per cent. is thereby shown in the cost of fuel per unit, 50 per cent. in oil and stores and 78 per cent. in water. These results must be considered as extremely satisfactory. We do not doubt that they will serve to direct further attention to the subject, and they by no means tend to the idea that the exhaust steam turbine is a passing fashion.

THE EFFECT OF VACUUM ON THE ECONOMY OF STEAM TURBINES.

BY R. M. NEILSON.

Summary.—The author deals with the important question of the effect of variation in the terminal pressure on the economy of steam turbines, and, from a consideration of the available heat energy in steam and the constructional requirements in steam turbines, explains why the efficiency of a turbine is affected as it is by change in the terminal pressure. A curve is given from which the effect of such changes on the steam consumption of any turbine may be estimated.

It is well known that the steam consumption of a steam turbine for a given output is reduced by raising the vacuum—*i.e.*, by a reduction in the terminal pressure. This reduction in steam consumption is not, as a rule, due to a better utilisation of the available energy in the steam but to the fact that the available energy increases very rapidly at low pressures.

A steam turbine has many efficiencies—thermal efficiency, overall efficiency, efficiency ratio, &c. It is not necessary to define these efficiencies on the present occasion.* It is to be remarked, however, that no efficiency, as commonly expressed, is of such a nature that the vacuum which makes that efficiency a maximum for any turbine is necessarily the most economical vacuum to employ for that turbine. The ascertaining of the most economical terminal pressure for any turbine involves a consideration of many things, including initial cost of turbine, steam generating plant and condensing plant, depreciation, interest, &c. The subject was dealt with in a Paper read recently by the writer before the Institution of Electrical Engineers,† and will not be treated of here, but it may be remarked—and, in fact, is obvious—that one of the most important considerations in determining the most economical terminal pressure is the reduction in the steam consumption of the turbine with decrease in terminal pressure. Now considerable divergence exists between the results recorded by different experimenters of tests of turbines of different types and powers, so that it is difficult to know what variation in steam consumption to allow for any given variation in terminal pressure. There is no doubt, in the writer's opinion, that in tests of steam turbines, terminal pressures are often inaccurately measured or wrongly expressed, inaccuracies being, in many cases, unavoidable with the vacuum gauges at the experimenters' disposal. The inaccuracies may be small and yet, if they occur at a low

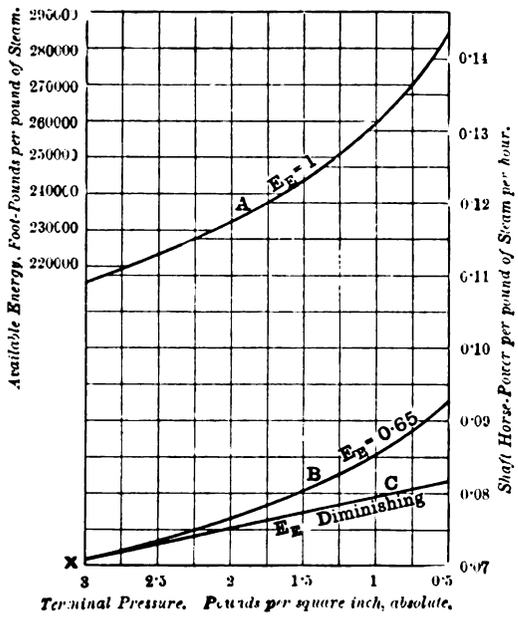

FIG. 1.

pressure, they may cause a very appreciable error in the estimation of the reduction in steam consumption for a given small reduction in terminal pressure.

Curve A in Fig. 1 represents, to the left-hand scale, the available energy given up by saturated steam expanded isentropically from an initial pressure of 200 lb. per square inch, absolute, to a terminal pressure indicated by the abscissæ. It will be noted that, as the terminal pressure falls, the available energy rises at an increasing rate—*i.e.*, every tenth of a pound fall in terminal pressure increases the available energy by a greater increment than the preceding tenth.

If the whole of the available energy of the steam supplied to a turbine were converted into shaft horse-power—*i.e.*, if the effective efficiency were 100 per cent.—curve A would represent, to the right-hand scale, the shaft horse-power per pound of steam.

Such a result is, of course, never obtained. The effective efficiency varies, depending to a certain extent on the type and design of the turbine and to a large extent on the full-load power of the machine and on the fraction of this power at which the machine is being run. What is noteworthy about a tur-

* The several efficiencies are defined in chapter V. in the fourth edition of the writer's book "The Steam Turbine." (Longmans & Co.)

† "Proceedings" Inst. of Elec. Engineers, January, 1910.

Digitized by Google

bine is that the effective efficiency does not vary greatly as the terminal pressure is altered; the turbine, within certain limits, converts nearly the same proportion of the available energy into useful work whatever be the terminal pressure. It is only when very low terminal pressures are reached that there is any rapid falling off in the effective efficiency.

If the effective efficiency of the turbine were constant for all terminal pressures, the shaft horse-power per pound of steam would be represented by a curve of the nature of curve B, Fig. 1; and, in fact, this curve represents the shaft horse-power per pound of steam for a constant effective efficiency of 65 per cent., the initial steam pressure being, as before, 200 lb. per square inch, absolute.

In practice, however, the effective efficiency falls off after the terminal pressure reaches a certain value depending on the type and design of the turbine. The volume of a pound of steam is very great at low pressures. For example, at a pressure of ½ lb. per square inch absolute, the volume is 633 cubic ft. To do the same justice to the steam at the lowest as at an intermediate pressure would involve, in some types of turbine, excessive dimensions, and a compromise has to be struck. Moreover, decrease in terminal pressure by increasing the available energy would necessitate an increase in the speed of rotation to obtain the same bucket efficiency, and the speed is usually controlled independently of the terminal pressure. A falling-off in effective efficiency at low terminal pressures is therefore to be expected, and such a falling-off always occurs in practice, although the point of commencement and the extent of the falling-off vary with different turbines.

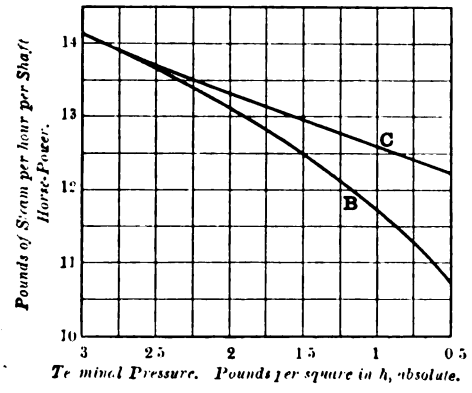

FIG. 2.

To get a good idea of what this falling-off amounts to, suppose that the effective efficiency remains constant with fall in terminal pressure till the latter reaches 3 lb. per square inch, and that thereafter, instead of following the curve B, Fig. 1, the straight line C is taken, which is a tangent to B at the point X, where the terminal pressure is 3 lb. per square inch. We are thus supposing that every decrement of terminal pressure below 3 lb. involves a constant (instead of an increasing) increment of shaft horse-power. Such a result would only occur in a turbine ill-suited for high vacua. For condensing turbines which have an effective efficiency of 65 per cent. with an initial pressure of 200 lb. and a terminal pressure of 3 lb., curves B and C may be considered as the limits within which lie all actual results obtained with lower terminal pressures.

Fig. 2 has been prepared from Fig. 1, and represents the consumption of steam per shaft-horse power, the curves B and C corresponding respectively to the similarly lettered curves in Fig. 1.

Fig. 3 has been prepared from Fig. 2, and shows the percentage reduction in steam consumption with reduction in terminal pressure. The curves have been lettered as before, and it will be seen that, whereas B (Fig. 3) rises with reduction in terminal pressure, C falls. Care must be taken not to misunderstand the reason of the fall in curve C. There is no increase in steam consumption with reduction in terminal pressure, but there is a diminution in the rate at which the reduction takes place. If C, Fig. 2, had been a straight line (instead of slightly convex downwards) C, Fig. 3, would have been horizontal.

It has already been stated that, when in actual practice the shaft horse-power curve passes through the point X in Fig. 1, it will always lie between curve B and curve C. It follows that in Fig. 3 likewise the corresponding practical curve must lie between curves B and C. Curves B and C in Fig. 1 are so close together that all test-obtained curves passing through X appear to be in fair agreement. When the results are set out in Fig. 3, however, great divergence appears. Fig. 3 is very useful in testing the accuracy of the measurements taken during tests; an unnatural curve in Fig. 3 will often be strong evidence of inaccuracy.

The writer has graphed the results, as published, of many steam turbine tests on a diagram of the same nature as Fig. 3. There were obvious inaccuracies in some of the results given. Other results which gave natural curves may, of course, also have contained inaccuracies, but, as many tests by different persons were taken, the mean result should be of use. This mean result is expressed by the curve D in Fig. 3, which, it is hoped, will be of service when it is desired to estimate the effect of change of terminal pressure on the steam consumption of any turbine and when no results, or insufficient results, are available from which a curve for the particular machine can be drawn.

The reason why curve D does not pass through the inter-

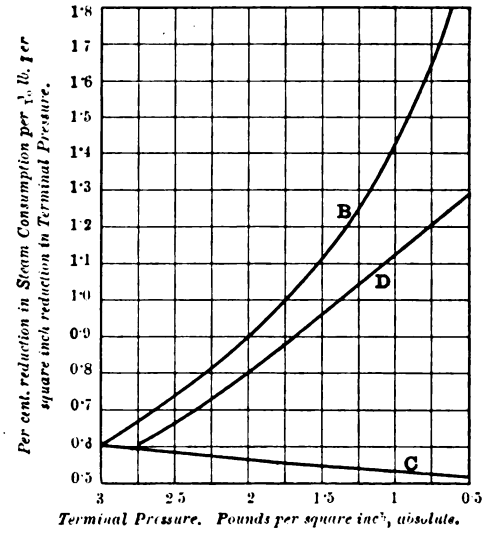

FIG. 3.

section of curves B and C is because the several turbines tested had different effective efficiencies at 3 lb. terminal pressure, the mean effective efficiency at this pressure being apparently less than 65 per cent.

As an example of the use of the curve, suppose that with a terminal pressure of 2·2 lb. the steam consumption of a turbine is 19 lb. per kilowatt-hour, and it is desired to know the steam consumption with a terminal pressure of 1 lb. Between 2·2 lb. and 1 lb. pressure the mean percentage reduction in steam consumption is 0·935 per cent. per ½ lb. reduction in pressure, and there are 12 tenths between 1 and 2·2. The total estimated reduction in steam consumption is, therefore, $12 \times 0{\cdot}935 \times \frac{19}{100} = 2{\cdot}13$ lb., and the actual estimated steam consumption with a terminal pressure of 1 lb. is, therefore, 16·87 lb. per kilowatt-hour.

The curve will, it is submitted, be found to give fairly accurate results for moderate power or high power steam turbines rotating at speeds usual in the driving of electric generators and supplied with dry saturated steam at pressures between 150 lb. and 200 lb. per square inch above atmosphere. The curve is not applicable to exhaust steam turbines, and may not be reliable if applied to machines under, say, 750 kw., or to machines in which highly superheated steam is employed. Moderate superheat, however, although greatly affecting the steam consumption, does not greatly affect the curve.

PHYSICAL SOCIETY.

At the meeting held on May 27th, at the Imperial College of Science, Prof. H. L. CALLENDAR, F.R.S., president, in the chair, a Paper

"On an Oscillation Detector actuated Solely by Resistance-temperature Variations"

was read by Dr. W. H. ECCLES. The experiments described in this Paper are offered as additional support for the author's hypothesis of the mode of action of certain types of electrical oscillation detectors. This hypothesis suggests that in detectors constituted of a loose contact the energy of the oscillatory current through the contact is transformed into heat at the contact and warms the matter there sufficiently to change its electrical resistance and, consequently, the steady current through the indicating instrument. The principal deductions from this hypothesis were worked out and were illustrated by experiments on iron-oxide coherers in a Paper read before the Physical Society on March 11th last. The present experiments are on a detector of the so-called "crystal rectifier" type, from which, however, the possibility of thermoelectric effects have been eliminated. This detector consists merely of a loose contact between two pieces of galena—a substance which, according to the author's theory, ought, by virtue of its large negative coefficient of change of resistance with temperature, to be a very efficient detector of electrical vibrations. The experimental curves obtained from a galena-galena detector are: the steady current curve, the sensitiveness curve and the power curve. The first has steadily applied E.M.F. as abscissæ, and current through the detector circuit as ordinates. It proves to be a curve which in general rises slowly at first, then quickly, and then slowly again; but if the circuit be arranged to have but little resistance other than that at the contact, the curve may possess a negative gradient at the point of inflection. The chief difficulty met in obtaining these steady-current curves arose from the slow movements of heat through the mass of the crystals—which have, of course, small thermal conductivity. This difficulty was overcome, and the true character of the curves brought to light, by allowing a proper time-interval for thermal equilibrium to be established before each galvanometer reading was taken. The sensitiveness curve has the E.M.F. applied to the detector as abscissæ, and the power passed to the indicating instrument as ordinates, the intensity of the electrical vibrations being of fixed amount. It is a curve which rises to a maximum near the point of greatest slope of the former curve, and thereafter descends slowly. The power curve has the power supplied to the detector in the form of electrical oscillations as abscissæ, with the power passed by the detector to the indicating instrument as ordinates, the steady E.M.F. applied to the detector being the best value. This curve is a straight line. The properties of this "crystal rectifier" are, therefore, just such as are logically deducible from the fundamental fact that the contact possesses a negative resistance temperature coefficient.

Mr. W. DUDDELL said the author was making progress with his thermal theory of coherers. He pointed out that in the experiments described considerable time was taken in determining the part of the steady current curve with negative characteristic, whereas in practice the changes were very rapid.

Prof. C. H. LEES remarked that Dr. Eccles had introduced simplicity into a very difficult subject. He agreed with the remarks of Mr. Duddell, and suggested using very minute points and surfaces so that less time would be occupied in securing thermal equilibrium. The working conditions would thus be more nearly reproduced.

The AUTHOR, in his reply to the remarks of Mr. Duddell and Prof. Lees, explained that in order to get a correct notion of the character of the steady current curves the curves should be drawn either very quickly or very slowly—that is to say, either adiabatically or isothermally. The former was really the curve required for strict quantitative correlation with the experimental facts of the behaviour of the detector towards high-frequency electrical oscillations. The isothermal curves actually obtained were the same in character as the adiabatic ones, to a sufficiently close approximation. If the masses of the crystals were reduced, as Prof. Lees suggested, in order to reduce the heat losses from the contact, then the metal leads to which the crystals were soldered might be brought near enough to the contact to make the heat losses larger, not smaller. The chief advantage of making the crystals smaller accrued from the reduction of that idle portion of the electrical resistance of the detector which underwent no temperature change of the kind desired. The author practically accomplished this already by copper-plating the crystals all over, soldering into place and then baring the small area of crystal required for the contact.

Mr. A. EAGLE exhibited a

"Resonance Transformer."

The transformer is practically a Rowland's coil. The capacity shunted across the secondary is so chosen that resonance is obtained with the alternating current supplied to the primary. The condition for this is $\left(L-\frac{M}{N}\right)Cp^2=1$, where L and N are the self-inductions of the secondary and primary respectively, M is the mutual induction between them, C is the capacity, and p is 2π times the frequency. In this way large condensers may be charged to a high potential very economically. Such a transformer forms a non-inductive load. Besides the great saving in current there is also a saving in energy due to the fact that the current from the secondary has not the tendency to flow through the spark-gap in the form of an arc discharge as in the general case. 110 watts have sufficed to run a spark with a condenser of $\frac{1}{10}$ mfd. capacity at a potential of 8,500 volts (R.M.S.).

The chief advantage of the resonance transformer lies in the character of the sparks. The voltage rises according to the law

$$V=V_m(1-e^{-kt})\sin pt,$$

where $1/k$, the time constant, is over 1 second. Hence, if V_s is the sparking potential, sparks will follow each other at intervals of $\frac{1}{k}\log_e\frac{V_m}{V_m-V_s}$. The interval can be varied within wide limits by varying V_m by altering the choking coil in the primary circuit. A succession of clear and distinct discharges is thus obtained instead of an indifferential stream of sparks with more or less of an arc discharge superposed on them.

A Paper entitled

"The Limitations of the Weston Cell as a Standard of E.M.F."

was read by Mr. S. W. J. SMITH. In this Paper the recent experiments of Mr. F. E. Smith on cadmium amalgams are discussed from the point of view of the modern theory of alloys. Theory and experiment alike suggest that there is no range at any temperature over which the E.M.F. of a Weston cell is absolutely independent of the percentage of Cd in the amalgam. Even if the materials are quite pure, the existence of surface energy must cause some variation. Within the range over which the E.M.F. is usually taken as constant the E.M.F. appears to rise, very slowly, with increase in the cadmium content. The rate varies, but is never more than a few millionths of a volt for 1 per cent. Cd. From the data it seems possible also to discover the precise way in which the use of the richer two-phase amalgams may lead to variability of the E.M.F. of the Weston cell. The interpretation advocated is that the irregularities are due to electrolytic skin effects arising out of want of uniformity of composition of the surface grains. The probable reason why the temperature coefficient of E.M.F. of a Weston cell, always small, actually vanishes near 0°C. is indicated. An outline of the way in which the phase rule can be used to exhibit the nature of the incomplete equilibrium of the Weston cell is also given.

Mr. RAYNER referred to hysteresis effects, which he said were a source of serious trouble when working with Weston cells. He gave details of the behaviour of a particular cell during a period in which the temperature of the cell was raised from 14°C. to 25°C. for three days, and asked the author if he could explain the observed variations of the E.M.F. on the theory he had advanced.

The AUTHOR, in reply to Mr. Rayner, said that, while he was not prepared (without further information) to give a fixed opinion concerning the behaviour of particular cells, he thought he had shown how to find the exact causes of any peculiarities for which pure amalgams might be responsible. The utility of the theory he had described lay in the fact that it should be possible, by means of it, to discover what the effect on the amalgam of any particular thermal treatment would be. His object had been to discuss one cause of some of the variations of the Weston cell, and to indicate a theoretical limit to the accuracy obtainable.

TEST OF 2,500 B.H.P. STEAM ENGINE.

On Friday last, at the invitation of Messrs. W. H. Allen, Son & Co., of Bedford, we had an opportunity of seeing one of the largest high-speed vertical engines which they have yet built running at their works. The engine has been constructed to the specification of Mr. Harper, chief engineer to the Corporation of Melbourne, and will be installed in the Melbourne electricity works by the side of three 1,000 B.H.P. engines, which are also of Messrs. Allen's make. The new unit will develop 2,500 B H.P., and is coupled to a 1,500 kw. direct current generator, which will supply energy for lighting and power in conjunction with the existing plant. The engine is a fine piece of constructional work, and follows the lines of Messrs. Allen's standard practice in high-speed engine designs. On the occasion of our visit both the engine and generator were seen running on three-quarter load. The illustration shows a general view of the complete unit as erected on the test plate for the official trials, which had been carried out on the previous day.

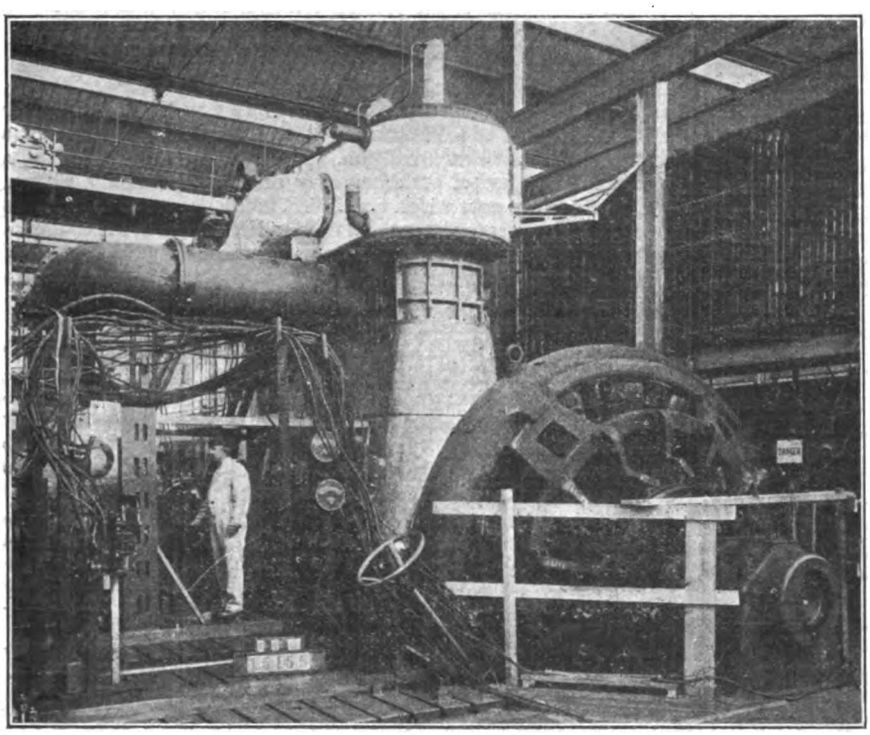
The engine is of the triple-expansion type, the cylinders being 22 in., 34 in. and 55 in. diameter respectively, and the stroke 26 in. The

Digitized by Google

working steam pressure is 160 lb. per square inch. The cylinders are not steam jacketed, but plainly lagged; the engine is designed to work on 160° F. superheat.

Piston valves are fitted throughout the engine, and the heavy reciprocating parts are steam balanced. The upper ends of the L.P. and I.P. pistons have guide rods fitted, and these pass through stuffing boxes in the cylinder covers. Relief valves are fitted to all the cylinders. The main bearings, top and bottom ends, eccentric straps and guides are lubricated by oil under 15 lb. pressure per sq. in. Two oscillating valveless pumps positively driven from one of the eccentrics maintain this oil pressure. The pumps are directly connected to a distributing box which extends the length of the crank chamber, inside and immediately below the guides. From this box the pipe connections are neatly taken to the various feed points. Two relief valves are fixed on the distribution box. The oil supply is taken from a tank which extends under the entire length of the bedplate. Included in the oil supply system is a large and efficient oil strainer, which is fixed at the governor end of the bedplate.

The governor is of the centrifugal type, and is placed vertically, being driven by bevel gearing from the crankshaft. The governor rod is carried directly up the engine to the throttle, which is of the tandem piston type. From full load to no load the variation is 3 per cent. at settled speed. The normal speed of the engine is 225 revs. per min.



2,500 B.H.P. ALLEN-G.E.C. SET ON TEST PLATE.

Immediately at the back of the engine is a standard pattern Allen condenser having a cooling surface of 2,240 sq. ft., and capable of dealing with 28,000 lb. of steam per hour when supplied with 1,400 gallons of circulating water per minute. The condenser barrel is so arranged as to ensure the efficient disposition of the cooling surface, and the uniform distribution of the steam to be condensed over the whole of the cooling surface, thus reducing to a minimum the quantity of cooling water required for condensation. The circulating water enters at the bottom of the condenser, circulates several times the length of the tubes, and leaves at the highest point, thus obtaining the maximum effect from the cooling water. The steam to be condensed enters the distributing chamber at the top of the condenser, whence it circulates transversely through the various nests of tubes, the vapour and water of condensation being withdrawn from the bottom of the condenser by the air pumps. The steam thus flows in a contrary direction to the circulating water on the "counter-current" principle.

The three-throw 12 in. by 10 in. air pumps are also of Messrs. Allen's make, and are direct coupled to a 12 H.P. direct-current motor, which runs at 145 revs. per min. At the other end of the air pump shaft is a 5 in. by 9 in. plunger pump, which is used to force the condensed water up to the level of the boiler feed tank, whence it is delivered to the boilers by the ordinary feed pumps.

Between the engine and generator is a 7 ton flywheel, 8 ft. diameter. The generator shaft is bolted directly to the flywheel boss without the intervention of a bearing, the flywheel and armature being hung between two bearings. The generator is an interpole machine, and has a capacity of 1,500 kw., with an overload of 20 per cent. for three hours, and was constructed by Messrs. The General Electric Co., of Witton, Birmingham.

CORRESPONDENCE.

HOPKINSON TESTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The method of analysis of the results of the Hopkinson test used by Dr. Drysdale, though not seen in any of the text books, is fairly well known. It is undoubtedly most successful, and is capable of yielding figures for the efficiency of dynamos with greater accuracy than is required for commercial testing purposes.

With reference, however, to the difference in the efficiency between motor and generator action, as shown in Fig. 2 of his Paper, the error introduced by improper allotment of the iron losses cannot amount to more than $\frac{1}{10}$th of 1 per cent. in the efficiency. The difference shown by the curves is, however, a real one and is an inherent feature of the efficiency curves of any machine as will be seen by what follows.

For any given output the armature current of a generator can be divided into useful current and exciting current, while that of a motor consists of useful or power current and "losses" current. The "losses" current when motoring will generally be greater than the exciting current, when generating for the same output, thus the motor armature current and C^2R loss will be slightly higher than those of the generator.

In this particular case we have, at 10 kw. output:—

Exciting current	2·5	amperes.
"Losses" current .	8·2	,,
Useful current	95	,,

The ratio of the C^2R loss in this machine when working as a generator to that of the same when operating as a motor will, therefore, be as $97{\cdot}5^2 : 103{\cdot}2^2$, or as $1 : 1{\cdot}13$. At 10 kw. output the C^2R loss is about 7 per cent., so that the difference in efficiency would be about 8 per cent. This practically agrees with the difference of about 1 per cent. between the curves.—I am, &c.,

East London College, June 7. JOHN F. FORREST.

We have submitted the above letter to Dr. C. V. Drysdale, from whom we have received the following reply:—

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am much obliged to Mr. Forrest for his letter and am glad to hear that the method of dealing with the observations advocated in my article has already found favour, although it had not come to my notice. But it has always been a matter of surprise to me that so important and widely used method as the Hopkinson test has had so incomplete a theory; and the method I proposed is so obvious that I can quite believe that it must have occurred to many. It is to be hoped that this discussion will result in a more complete treatment in text books.

Coming, however, to the point which Mr. Forrest raises, I am afraid that the difference between the generator and motor curves cannot be dismissed as lightly as he does. His remarks about the armature copper losses are correct in principle, and would account for a difference in efficiency between

Digitized by Google

UNIVERSITY OF CALIFORNIA

a machine running as generator and as motor, under the same conditions of magnetisation, speed and output. But I am at a loss to account for his assumption that the error introduced by wrong apportionment of the iron losses cannot account for more than $\frac{1}{20}$th per cent. in the efficiency. As a matter of fact, we have made exhaustive tests upon the losses of these machines, and the two exciting currents correspond to core inductions of 8,500 and 7,000 in the generator and motor respectively, and a difference in the iron losses of 120 watts or 1·2 per cent. of the output. Further, I did not speak of iron losses but of "fixed" losses, which include excitation, accounting for an additional difference of 40-50 watts, thus making a total difference in these "fixed" losses of about 160 watts, which is nearly double the difference in the armature C^2R loss referred to by Mr. Forrest.

I hope to publish these other tests shortly, and will defer further discussion of this subject till then. In the meantime the approximate method seems good enough for most purposes.—I am, &c.,

Reigate, June 14. CHARLES V. DRYSDALE.

FISCAL POLICY AND THE ELECTRICAL INDUSTRY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: When you reported the first instalment of the manufacturers' debate you expressed a doubt whether the disputants were properly equipped for such a discussion in point of economical knowledge. May one, who has at any rate been a life-long student of economics, venture to think that your doubt has been largely justified? Political economy must be not only a science, but a very difficult science, exceptionally requiring special study, since so many able men seem unable to grasp its simplest principles. I even venture to think that the opinion of the man in the street on the future of radium would be about as valuable as that of the average manufacturer, uncorrected by special study, on a problem in political economy. The debate frequently illustrated this.

You yourself, sir, ask why this should be the only country in the world for which Free Trade is good. May I say, with all respect, that economists doubt, or even deny, the fact? The most that any economist of repute has ever said is (with Mill) that Protection may be good for infant industries—the trouble, however, being that, when the infants have become adults, you cannot get rid of the Protection. If you ask the question in another form—Why is it that we alone have had Free Trade?—the answer is simple; we are the only nation that *could* have it. We were first in the field and occupied the ground so effectually that other nations could not, unprotected, compete with us, even in their own markets. To them Protection was a necessity and Free Trade an impossibility.

The tactics of the Tariff Reform speakers in the debate seem to have been to set aside statements, however good their authority, that did not agree with their conclusion, and to evolve out of consciousness others that did. This led to some monstrous assertions. One speaker informed the meeting that 90 per cent. of our tramway material came from America! My friend, Mr. Anderson, is accountable for two monstrosities. Discarding the Board of Trade figures of unemployment as applying only to trades unions, he evolved the statement that, outside the unions, unemployment was "appalling," forgetting, I think, that just as the Tariff Reform imagination is held in check by the Board of Trade figures with regard to skilled employment, so it is, or should be, held in check by the pauperism tables as regards unskilled. Any "appalling" unemployment must be reflected in the column headed "Adult, able-bodied" paupers, and none is. He then repeats the statement that Sir H. Campbell-Bannerman did not make—if I may be allowed a "bull"—that 12 millions of our people are on the "verge of starvation." Our proportion in Birmingham would give us about 150,000 persons weak and fainting from want of food—a conclusion too nonsensical for words. When an able man quotes (or thinks he quotes) with approval such a manifest absurdity, one can judge how much thought he has given to the subject. It is clear that he and others have never tried simply to think out and ascertain the truth, but merely have looked round for arguments—any are good enough—to support a conclusion they have determined shall be true, happen what will; a state of mind fatal to scientific inquiry. Mr. Hirst actually thanked his friends for the "fervour" with which they had supported him. That is just it. I could not ask for a better epithet for the Tariff Reformer than "fervid." But fervour is not supposed to be favourable to dispassionate inquiry.

I now come to sins of omission. I think I shall not be misrepresenting these speakers if I say that underlying all their argument is the idea that profits, satisfactory to manufacturers, form an essential element in national prosperity. That is a mistake. So long as profits are just sufficient to keep manufacturers from shutting up shop, that is all that is necessary. National prosperity is measured by one thing and one thing only—the total production of wealth. And of that I know only two measures, the statistics of employment and the import of raw materials. Incidentally, I observe that both are at the present time in a strikingly satisfactory state, and are still improving. This by the way. The immediate point is that no Tariff Reform speaker tried—no Tariff Reformer has ever tried—to show just how Protection tends to increase total production and employment; bearing in mind, of course, that we do not produce gold and silver, and have nothing but goods made at home wherewith to pay for goods bought from abroad. I challenge Mr. Hirst to free himself from generalities and show the *modus operandi*; how precisely it comes about that Protection increases total production. This is the fundamental point; nothing else really matters.

It is the easiest thing in the world to exhibit the opposite tendency—how Protection tends to *diminish* employment and the production of wealth, as thus: Protection, if it protects, raises prices. (I decline to argue with anyone who is capable of denying this.) Prices being raised, the purchasing power of the community is reduced; our people cannot buy so much; demand, and with it production, falls off, and with production, employment. I think I am tolerably conversant with the literature, and I venture to say that no Tariff Reformer has succeeded in showing—has ever fairly and squarely attempted to show—any tendency of Tariff Reform calculated to counteract this. He may simply assert it with Mr. Chamberlain; but a child in economics can refute him. He should show the steps.

If Protection cannot increase total production, or even reduces it, but can and does increase the profits of manufacturers, clearly its total result is merely to affect distribution. The manufacturer gets more of the wealth produced by the nation, and other people less. I know he will "hold it villainy to have it thus set down," and will recoil from it on paper. Will he recoil from it in practice? I wonder. He may or may not be fully conscious of the fact, but that is what he is really driving at. He may or may not succeed in deluding himself with the idea that what will be good for him will also be good for other people; but, if he really believes it, he *is* deluded. At any rate I, for one, after much searching, have never found any argument that will hold water for a moment enabling me to share his belief.

I would if I could. My partner (Mr. Arthur Chamberlain) and I would be richer men if we had Protection. As he once said, "Give us Protection and we employers will show you a thing or two in the way of rings and trusts that will astonish you." In this controversy we have consistently argued, he and I, against our own interests. How many Tariff Reformers can say as much?—I am, &c.

Birmingham, June 14. GEORGE HOOKHAM.

EFFICIENCY OF SHORT SPARK METHODS OF GENERATING ELECTRICAL OSCILLATIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Galletti's letter in your last issue contains two propositions. In the first he implies that a low efficiency of transference of energy from the primary to the secondary

Digitized by Google

circuit of a generating set is necessarily associated with a small change in the resistance of the spark-gap in the primary circuit, when the secondary circuit is put in and out of action. This is obvious for efficiencies as low as the ones mentioned by Mr. Galletti, but these are not under discussion.

The second proposition refers to higher efficiencies. Quoting an experiment in which the aerial current and the primary current were both doubled when the power supplied was quadrupled, your correspondent shows *by equating the efficiencies before and after doubling the current across the gap* that the resistance of the spark-gap must have remained unaltered by doubling the current. To equate the efficiencies begs the whole question.

That a change of resistance of the gap probably does take place can be deduced in an interesting manner by combining our absolute measurement of the efficiency with Mr. Galletti's experimental fact that $i_1 = 2i_2$, where i_1 and i_2 were the primary currents when the secondary circuit was in action and out of action on a certain occasion.

The efficiency as determined from our calorimetrical measurements was 49 per cent., and using this figure and the expression for the efficiency given in our last letter we get :—

$$\frac{K_1 i_1^2 - K_2 i_2^2}{K_1 i_1^2} = 0{\cdot}49,$$

where K_1 and K_2 represent the unknown resistances of the gap when the currents i_1 and i_2 are flowing. This gives $K_2 = 1{\cdot}96K_1$, which is in accordance with our previous suggestion that the resistance of the gap may be halved when the current flowing through it is doubled.—We are, &c.,

W. H. Eccles.
A. J. Makower.

South Western Polytechnic, London, S.W., June 14.

LARGE "WITTON" GENERATOR FOR MELBOURNE

As mentioned on another page of this issue, we had the opportunity last week of inspecting a large electric generating plant which is being shipped to Australia for installation in the Melbourne electricity works. The following particulars of the generator, which has been supplied by the General Electric Co. and is direct coupled to an Allen engine, will doubtless prove of interest.

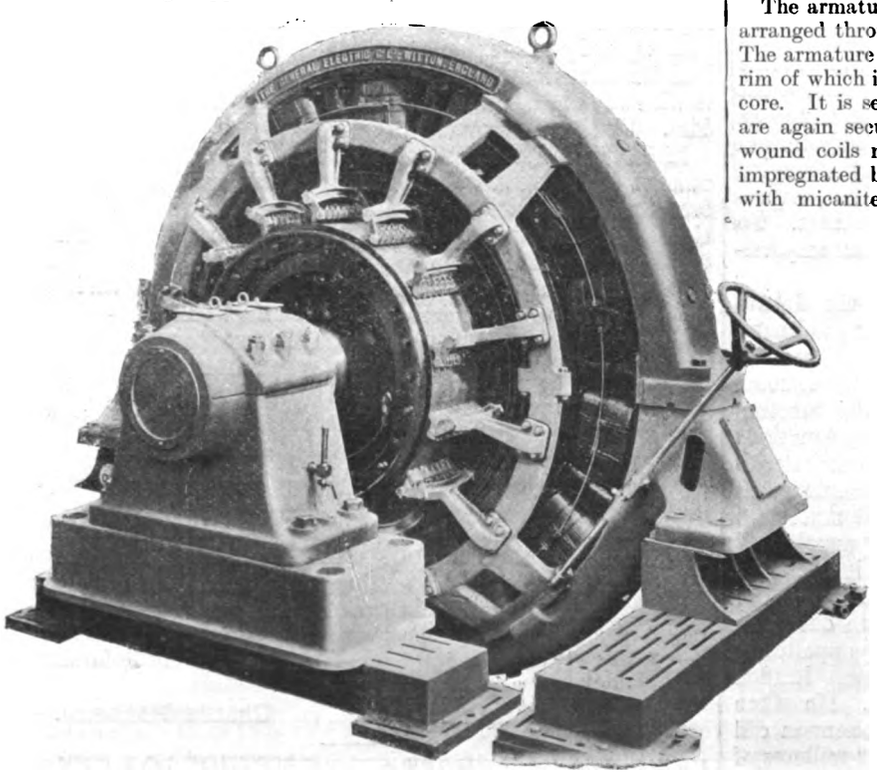


Fig. 1.—General View of 1,500 kw. "Witton" Generator for Melbourne.
(The General Electric Co.)

It consists of a 1,500 kw. shunt-wound continuous-current dynamo fitted with commutating poles, and has been designed to give full load either at a pressure of 480 volts and a speed of 225 revs. per min., or at 530 volts and 235 revs. per min. The magnet frame is made of cast iron and is split horizontally, thus permitting of easy inspection for cleaning the armature or changing the field coils. The main poles are built up of stampings and are fixed to the frame by means of strong steel bolts, whilst the pole tips are shaped in such a way as to give the best field for commutation with a fixed position of the brushes. The shunt windings of the field magnets consist of bobbins wound on spools of special insulating material and are taped all over and impregnated. Any spool can be removed and replaced without affecting any other part of the machine. The commutating poles are placed between the main poles and are made of cast steel, wound with bare copper strip. They are excited by the main current of the machine.

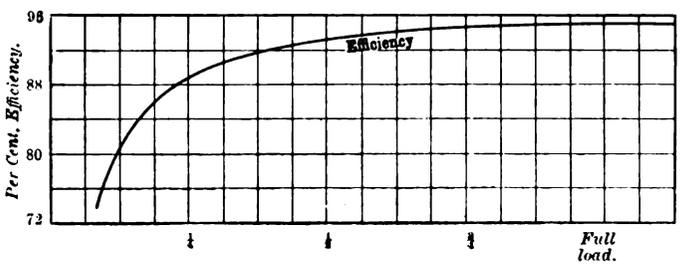

Fig. 2.—Curve showing Efficiency of 1,500 kw. "Witton" D.C. Generator.

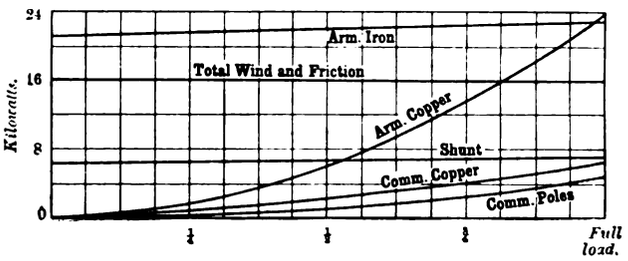

Fig. 3.—Curves showing Losses.

The armature is of the drum type, ample ventilating ducts being arranged through the core and between the core and end-plates. The armature spider is a massive casting in the form of a wheel, the rim of which is formed by the assembled stampings of the armature core. It is securely fastened between two strong end-plates which are again secured to the spider. The winding consists of former wound coils made up of copper strip, each coil being taped and impregnated before being inserted in the slots. The slots are lined with micanite tubes closed up by means of maple wedges. The binding of the armature consists of steel bands locked by means of strong steel cotters.

The commutator is built up of hard-drawn copper bars, insulated with mica, and erected on a heavy cast-iron ring bolted to an extension of the armature spider. The commutator thus becomes independent of the shaft, and can be erected in one piece with the armature. The lugs connecting the commutator bars to the winding are of ample section and are kept as wide as possible, so as to ensure efficient ventilation of the commutator surface. A set of equalising connections is also provided to ensure perfectly equal distribution of the current in the various parts of the windings and of the commutator.

The brushes are of carbon, and on each spindle there are several small brushes, each having its own brush-holder, this system being found to be the most satisfactory when dealing with large currents and many poles. The brush-holders are of gun-metal and of the "sliding-box" type, the moving part being connected to the block and the spindle by means of flexible copper leads, so that but little current is carried through the sliding contact; and the shape of the carbons is such that there is no alteration or shifting of the contact surface peripherally due to wear of the carbons. As will be noticed from the view of the generator given in Fig. 1, each spindle carrying one row of brush-holders is supported at both ends by a strong arm insulated from the rocker ring, and is constructed so that it can be adjusted peripherally independently

Digitized by Google

of the others, thereby securing accurate spacing of the brushes. Every alternate arm is connected with copper collecting rings which run round the rocker, and from these rings the current is taken away to the terminals by means of large cables, sufficient flexibility being allowed for rocking the ring and adjusting the brushes whenever required. The rocking ring is supported by the field frame of the machine, whilst the collecting rings are so placed that they are mechanically protected from accidental contact. It is interesting to notice that the terminals of the machine are placed at the bottom of the yoke, inside the pit, which enables the cables to be taken directly to the switchboard through cement troughs laid in the ground.

The generator was specified to give an efficiency of 95 per cent. at full load, 94·2 per cent. at three-quarter load, 92·5 per cent. at half load, and 85·5 per cent. at quarter load. It will be seen from Fig. 2 that these results were obtained on test.

Fig. 3 is interesting as showing the various losses in the generator, which had to run sparklessly up to 20 per cent. overload and to take this overload continuously for two hours without injurious heating; whilst the temperature rise after a six hours' run on full load did not exceed 70°F. on any part of the machine.

FIFTEENTH ANNUAL CONVENTION OF THE INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION.

(*Concluded from page 388.*)

Mr. LEA (Lea Recorder Co.) said that his water recorder had been developed as the result of experience with South African mining plant, in the running of which details of cost were required. He considered that much of the money spent in CO_2 recorders was well spent, and the cost was proportionately small. He was of opinion that the running of plant should be taught in technical schools.

Mr. R. ROWLAND (Stretford) thought that the draught should be regulated by the main dampers. He considered that CO_2 recorders were a good investment. He had reduced his coal consumption considerably.

CHEAPENING THE COST OF MAINS AND SERVICES.

Mr. S. J. WATSON (Bury) opened the discussion on Mains, in the absence of Mr. S. E. Fedden (Sheffield) owing to illness. He stated that although the cost of generating plant had much decreased, that of mains was practically the same as 10 or 15 years ago. Many cables were now 20 per cent. more costly than in 1902. Again, it was impossible much to reduce the cost of excavating and making good. Also, as the mechanical protection varied with the insulation, it was only possible to economise on the conductor and insulation. In comparison with a low-tension cable at 8s. per yard, of which sum the insulation cost 3s. 5d., a similar high-tension three-core cable cost 9s. 4d. per yard, or 16 per cent. extra cost for 10 times the capacity. Therefore, three-phase distribution should be more considered. He thought that the Board of Trade regulation re pressure variation might be relaxed, owing to the use of metal lamps, with considerable advantage as regards mains. He regarded aluminium as impracticable for underground cables owing to the increased diameter necessary, but it was advantageous for overhead construction. An aluminium overhead line at Bury one mile long had been erected at one-third to one-quarter the cost of an underground main. Mechanical joints were used, and a satisfactory job had resulted. He suggested the use of three-phase (three-wire) current at 400 volts and house transformers at low pressure.

Mr. F. E. AYTON (Ipswich) said he had used solid and armoured services with little difference in cost. Six yards of 7/20 laid solid cost £1. 19s. 9d. and with armoured twin cable £2. 4s. 5d. The cost, therefore, was not much affected by the service cable, and a new type of cable was not so important as cheaper service fittings and meter.

Mr. B. SANKEY (Whitehaven) gave figures for 10 yards of 7/16 cable as £2. 16s., or with fittings £3. 6s. 7d.

Mr. W. G. PICKVANCE (Wrexham) said he used lead-covered or bitumen cable in troughing, and the average service cost £2. 5s. He thought it best to protect the cable with bitumen.

Mr. J. H. BOLAM (Weymouth) thought the density factor more important than the load factor in many cases, and the cost of mains and the density of the area to be the controlling factors. He thought services should be not less than 7/18 for mechanical reasons.

Mr. F. C. RAPHAEL suggested that services should be laid with mains to reduce cost.

Mr. W. W. LACKIE (Glasgow) gave detailed figures. The average cost of 60 services during the last two months was £4. 6s. 6d., as compared with nearly £7 a short time ago. The reduction was due to specialisation.

Mr. W. A. VIGNOLES (Grimsby) thought that smaller distributors were now possible owing to the advent of metal lamps, and he had laid 3,700 yards of 7/16 three-core cable at 1s. 8d. per yard. Labour was not a fixed quantity; it varied from 3s. 6d. to 9d. per yard, making it desirable to lay long lengths at one time in the case of cheap cables. He considered that transformers for rows of houses were not always possible. He supplied houses in pairs, and had reduced the service cost per house to 30s. He had supplied 14 semi-detached cottages by means of looping at a cost of 30s. per cottage.

At the close of the meeting, members adjourned to the Grosvenor Hotel, where luncheon was served. This afternoon the St. Andrew's Cross power station of the Glasgow Electricity Department, the Coplawhill works of the Tramways Department, and the electricity works of the Govan Corporation were visited; whilst some members went further afield and inspected the power station of the Clyde Valley Electric Power Co. at Yoker, the Partick electricity supply station, the shipbuilding works of Messrs. Beardmore at Dalmuir, and the works of Messrs. Babcock & Wilcox at Renfrew.

This evening the annual dinner of the Association is being held at the Windsor Hotel and is very well attended.

CONGRESS OF THE TRAMWAYS AND LIGHT RAILWAYS ASSOCIATION.

This congress was opened on Thursday last week at 10:30 a.m. in the Imperial Hotel, Dublin. In the unavoidable absence of the Hon. Arther Stanley, M.P. (Chairman of the Association), the chair was occupied by Mr. James Devonshire. A Paper on "THE DUBLIN UNITED TRAMWAYS," by Mr. R. S. Tresilian, secretary of the Company, was taken as read. This was followed by a Paper

"BRAKESHOE STANDARDISATION,"

by Mr. J. A. Panton.

Prof. ERNEST WILSON, in a written communication, gave the following figures, obtained in the Siemens Electrical Engineering Laboratory, King's College, London, from tests made with a Peacock geared brake spindle. The effective length of handle was 10¾ in.; gear ratio, 14 to 34; diameter of drum on which the chain was finally wound, 2½ in.; links of chain (flat) 2¼ in. maximum length, 1¼ in. maximum width; diameter of iron, approximately, ¼ in. When lying on the 2½ in. drum the chain added about ¼ in. to the radius; the leverage as between handle and chain was therefore 14·9, neglecting friction.

The following were some figures obtained for the relation between the pull on the chain and the pull on the handle, and the calculated results:—

Pull on 10¾ in. handle in pounds.	Pull on chain in pounds.		Difference as a percentage of calculated pull.
	Observed. (approx.)	Calculated, neglecting friction.	
10	125	149	16
20	265	299	11
30	380	447	15
50	625	745	16
70	830	1,045	20
100	1,170	1,490	21·5
120	1,380	1,790	23

Before the shoes were reached there was the additional pull due to the brake rigging. Mr. Panton had given figures relating to Ackley and Peacock geared brake spindles, but omitted certain details, and also did not state if the figures were the result of a test or calculation. This was important. Further, he did not state if the pull obtained was at the chain, or if the pull due to the rigging was included. The makers of the Peacock brake usually recommended for light cars the use of a handle not exceeding 10½ in. in length. It was probable that a 10¾ in. handle was more generally suitable for the majority of cars in use in this country than were the handles 12 in. and 14 in. long. In conclusion, it seemed very desirable in geared brakes of the Ackley and Peacock types, that the shape of the drum should be such that whilst the chain was passing from the large to the small part the change in leverage should be gradual.

Mr. J. R. SALTER (South Lancashire Tramways Co.) pointed out that the number of car-miles run with a given brake block was a very doubtful criterion, since the wear of the block unit obviously depend upon the track, the frequency of the stops and the handling of the brakes. He proceeded to give the opinion of his assistant, Mr. Edwards, upon the Paper. Mr. Edwards agreed as to the desirability of standardisation, but thought that the author had put the cost of brake renewals too high at 10 per cent. of car maintenance: 2·2 per cent. would be nearer the mark, or 0·012d. per car-mile. The author had also put the scrap weight unduly high and the scrap value too low. He preferred a composite block to a cast-iron block; the former cost more but wore so much longer as more than to compensate for extra cost. Under identical conditions he had found 4,000 car-miles for cast-iron blocks and 9,000 car miles for composite blocks.

Mr. F. E. SAUNDERS (Maidstone) agreed that car-mileage of brakes depended on the track and that 10 per cent. of car maintenance was too high a figure for brake block renewals. He thought the figure of £10 per ton for brake blocks too high, and gave £5 for cast iron and £8 for chilled blocks as reasonable figures.

Mr. R. J. HOWLEY agreed as to the desirability of standardisation, which had been done to a certain extent in America. The object of the designer should be to reduce the amount of scrap. He had been experi-

Digitized by Google

menting with a brake shoe, renewable and reversible, and pointed out that in considering the metal to be used it was important not to neglect the convenience of passengers and to provide for a smooth retardation of the car. He preferred good grey cast iron to chilled blocks.

Mr. A. A. BLACKBURN (Belfast) wished to know if the figures had been taken from the Liverpool overhead lines; if so, they were no data for city lines. He agreed with former speakers as to different wear on different lines, and instanced a line of track along a sandy seafront where the wear of certain seasons was quite abnormal; £10 per ton was entirely too high a price for brake blocks. As to the absence of flanges in the type advocated by the author, he did not think there was much in it, as it was the track and not the brakes which wore the flanges.

Mr. MCCULLOUGH (Liverpool) advocated composite blocks, since they produced fewer flats. It was quite possible to manufacture brake blocks to give any desired result. Brake troubles were due to variation in the power applied and a desirable improvement was to limit this variation.

Mr. PANTON (in reply) defended the 10 per cent. of car maintenance as a figure for brake renewals as accepted American practice. He said the partially chilled brake blocks would cost £10 per ton, but it was worth paying; and he admitted that cast-iron brake blocks could be got for £5, but doubted whether it was worth while to use them. As to the form experimented on by Mr. Howley—so long as the wearing part could be fitted and reversed it would fulfil its purpose.

The Paper

"TRAMWAY ECONOMICS"

(of which an abstract was given in our last issue) was read in a condensed form by the author, Mr. J. R. Salter.

Mr. C. W. MALLINS (Liverpool), in a written contribution, corrected the statement in the paper that the report of the year 1908 on the Liverpool tramways was by Mr. Bellamy, and claimed that it was by him (Mr. Mallins). He argued at length against the appointment of engineers as managers, claiming that the duties required quite other than engineering training. He thought a service should not be increased or diminished without a very careful analysis of the figures, and gave an example from his system where a reduction of service gave an increased profit.

Mr. S. SELLON thought the Paper one of the most valuable ever presented to a tramway congress. On the question of engineer managers, he pointed out that Mr. Mallins spoke from the experience of a large city, able to pay highly both engineer and manager. This was not possible in small undertakings. He also alluded to the impossibility of comparing the efficiency of working of different lines unless one knew the exact conditions of each. It was now generally agreed that the comparison of gross expenses with gross receipts was not of much value. So long as a man knew that he was getting every penny of net earnings he need concern himself little about the proportion of gross receipts to gross expenditure. As to the common misconception as to the impossibility of making a reasonable profit on a line with small receipts—a small 7 mile line known to him, capitalised at £10,000 per mile and earning only £2,000 per route mile, paid 6 per cent. on the preference shares, 6 per cent. on its ordinary shares, and put by a fair amount for depreciation. In this connection he complimented the Dublin United Tramway Co. on their financial success with very low earnings (9d.) per car-mile; and this in spite of the fact that the mileage per head of population was greater than in richer cities. He believed that railless traction would take the place of motor 'buses, especially in the matter of testing volume of traffic at small expense. The Mercedes system was the best, in his opinion.

Mr. H. E. BLAIN (West Ham) especially appreciated the value of the "Density Factor" in the author's Paper.

Mr. E. HATTON (Newcastle-on-Tyne), alluding to the strictures of Mr. Mallins on the engineer manager, gave it as his opinion that the Liverpool figures showed that if the manager were an engineer or had control of the engineer it would be better for Liverpool.

Mr. W. CLOUGH (Bury) thought that Mr. Salter's Paper gave tramway managers valuable material for thought; but he took exception to the part dealing with car-mileage receipts and expenses, and thought that the author had mixed up certain standing charges with running expenses. The really important matter in any given case was to know the critical point at which increased earnings just equalled increased cost, *i.e.*, where no increased profit was possible. Commenting on the Heywood case, he laid it down as essential that there should be one authority empowered to settle the through fares in cases of running powers, and that if should not be left in the power of one authority along the route to raise the fare on its portion and nullify the whole agreement; in particular he objected to clause 9.

Mr. R. J. HOWLEY noticed that the "Density Factor" was simply earnings per mile of route, divided by a constant and given a fancy name. His idea of standing charges was that they were a fixed quantity with no reference whatever to car mileage. The really importan question was whether with increased car mileage, in any given case, the net revenue was increased. He advocated a system of discount tickets available during the slack hours. As to the size of cars, he preferred big cars, in spite of extra consumption of power during slack hours, principally because of saving in wages. In the matter of running power, he believed there was only one fair way—each party to get fares in its own district.

Mr. R. W. CRAMP (Birmingham) thought there was this at any rate in the Heywood agreement that it had put on the statute book an Act giving power to a small authority to run into a larger one to the advantage of both. He advocated a central tramway board.

Mr. SALTER (in reply) said that the report of 1904 (not 1908) by Mr. Bellamy was the one alluded to. As to Mr. Mallins' contention that engineers were not suitable managers, he pointed out that certain systems were so large and profitable that they could afford the luxury of great independent departments without much affecting the financial results. Smaller concerns could not afford this. Buxton, for instance, could not be run so economically unless by an engineer. Non-engineer managers succeeded not because they were not engineers, but in spite of that fact. Such would succeed anywhere, and were not worth £1,000 a year. Dealing with Mr. Clough's contention as to running and standing charges, he held that Mr. Clough's contention, if true, helped him (Mr. Salter), because if the standing charges were increased this increased the necessity for extra car-mileage. He admitted that running charges were not proportional to car-mileage, but took them as those charges which occurred only when the lines were run and ceased if they were shut down.

A Paper on "RAILLESS TRACTION," by Mr. Harry England was next summarised by the chairman.

Mr. A. H. POTT (Metropolitan Electric Tramways) represented the only company which had yet experimented with a trolley 'bus in England. He appreciated the system as a pioneer or feeder system for existing trams and so workable on same system throughout. The Mercedes system praised by Mr. Sellon was—from this point of view—the least suitable of any. He thought the figures given for the trolley 'bus system were much more favourable than were possible in practice. A trailer car could be used; the saving in depôts could not be realised—corrugated iron sheds were not used for tramcars, why should they be used for 'busses. Wooden poles were not used for tramways: why should they be used for motor 'buses? It was unfair comparison to credit the motor 'bus with all sorts of cheap devices not used in tramway practice. The figures given for repairs and maintenance were much too low. He accepted the motor 'bus as available for pioneering, and believed they would have to pay towards road maintenance.

Alderman IVEY thought that if their use brought to a head the unfairness of the present position of the motor 'bus in competition with the tramway, in that the former paid nothing for the use of the road, their advent would be of service.

Mr. SELLON alluded to the Paper as damning the tramways in favour of an experiment.

The Paper "SHOULD THE ACT OF 1870 BE REVISED" was taken as read, and led to no discussion.

E.M.F. ELECTRIC FANS.

A line of fans very suitable for domestic and office use has been placed on the market by the E.M.F., Ltd., and various details of these, both technical and commercial, are contained in a catalogue

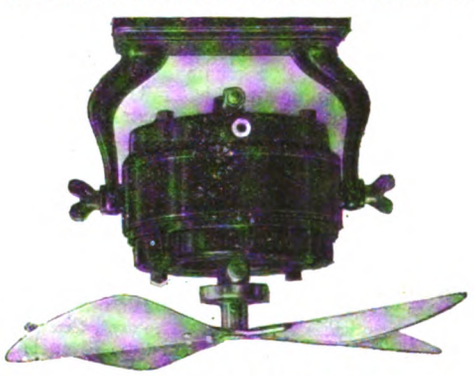

FIG. 1.—"E.M.F." CEILING FAN.

recently issued by them. We commend this catalogue to the attention of all those who intend to purchase this useful equipment.

All the fans are thoroughly well made and are the outcome of considerable experience in this class of work. It is claimed that the material used is of the very best, while the motors run noiselessly and have a high efficiency. It may be mentioned that all the single-phase and three-phase fans are fitted with induction motors, so that there are no brushes or commutators to give trouble, while the bearings are of the adjustable type and are arranged so that the wear can be taken up. A great number of experiments have lately been carried out on the question of the most suitable shape of blade used in fan work, and it is, therefore, interesting to note that the E.M.F. Co. have taken advantage of the figures thereby obtained, and have accordingly arranged their blades to give the greatest displacement of air obtainable.

Turning to the fans themselves, it may be well first to draw attention to a piece of apparatus which should find an exceedingly wide application. It consists of a special combination apparatus, which has been designed to allow one fan to do the work of table, bracket and ceiling fans. To do this the fan motor, fan and carrying trunnion are fixed by means of bayonet slots in a special base, and can be clamped

Digitized by Google

in that position by means of a milled nut. It is, therefore, possible, by arranging these base blades round the room in various positions, to use the same fan either as a ceiling, bracket or desk fan, while, of course, it can be taken from room to room as required.

What may be called the domestic type of fans made by the E.M.F. Co. are supplied in three sizes 10, 12 and 16 in. in diameter, and taking 26, 55 and 90 watts respectively. They can be supplied on a solid base with a swivel and trunnion, or on a bracket, and also in connection with the special equipment mentioned above. The motors are designed for pressures between 50 and 120 and also 200 to 240 volts when continuous current is employed, and from 70 to 130 and 150 to 220 volts when alternating current is used.

A more serious type of fan is that shown in Fig. 1. This has been specially designed for tropical climates, and is arranged for fixing on the ceiling. The example shown is of the alternating-current type, and is fitted with four brass blades. This is the standard with alternating-current motors, but on continuous-current motors either wood or aluminium blades can be used. These fans are made in various sizes from 24 in. to 60 in.

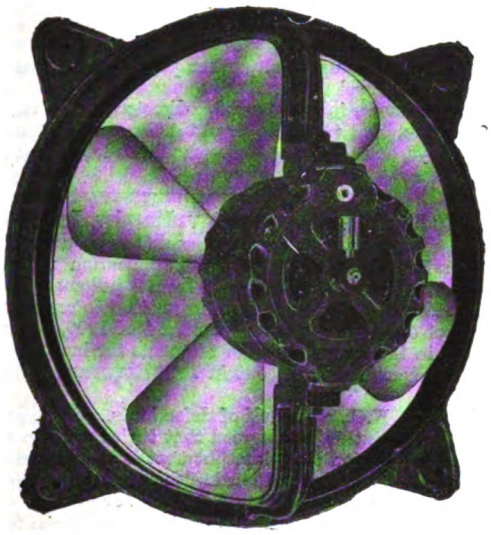

Fig. 2.—"E M.F." Porteole Fan.

Another very useful type of fan made by this Company is the port-hole fan shown in Fig. 2. These fans are fitted with motors of a semi-enclosed type, and can be designed to run either on continuous or alternating current. They are made in three sizes, having diameters of 10, 12 and 16 in. respectively. The E.M.F. Co. are also making a speciality of small motors similar to those used in fan work, capable of being applied to such applications as grinding and polishing machinery.

LEGAL INTELLIGENCE.

Attorney-General v. Leicester Corporation.

Mr. Justice Neville commenced the hearing of this action on Monday.

Mr. Felix Cassell, K.C., for the Attorney-General, said he sued as the relation of Mr. Utly, a ratepayer at Leicester, to obtain a declaration that defendants were not entitled to carry on the business of electrical contractors, and he also claimed a declaration that defendants could not expend their funds for that purpose, and an injunction to restrain them from so doing. Defendant Corporation obtained in 1890 a provisional electric lighting order which authorised them to supply electrical energy within the municipal area. Defendants did not obtain any express power to enable them to supply fittings, motors, &c., and the point at issue was whether, if there was no such express power, the Corporation was authorised to carry on such work as being incidental to the undertaking of electricity supply. Defendants contended that, apart from their special statutory powers they, as a Corporation at common law, had powers apart from their statute. Even if that were so he did not think that would very materially affect the plaintiff's case. There was an issue of fact and also an issue of law to be tried. Plaintiff's case was that defendants carried on nothing more nor less than an electrical contractor's business. In 1894 they opened show-rooms where they had offered for sale every kind of appliance in connection with the use of electricity. His contention was that the undertaking which defendants were authorised to carry on was the supply of electrical energy, and that they were expressly debarred from going beyond the business of supply and undertaking the supply of fittings, wiring materials, &c., used in the consumption of electricity. He submitted that defendants' power stopped when they had supplied electricity to the premises of consumers. As soon as the consumer turned on the switch defendants' power ceased. Defendants had power to do anything which was incidental to the business of supply, such as the purchase of coal, putting up a generating station, &c., but the power must be limited to that which was incidental to such a business. Up to a certain point they had admissions from defendants, admissions which, he submitted, were enough for his purpose, but he should call evidence which would carry the case far beyond those admissions. He contended that the whole of the things mentioned in the statement of claim were illegal and *ultra vires*. Evidence would be given to prove that at the show-rooms defendants supplied lamps and other things to anyone who chose to walk in and ask for them. One man who was not a resident in the borough walked in, asked for a lamp and bought one. Another thing he especially complained of was the supply of electric bells. In any event those things could not be said to be incidental to defendants' business. In another case defendants supplied a dynamo for an independent installation, and those things could not be incidental to the supply of electrical energy. Defendants were carrying on that business at a considerable loss. His submission was that the Corporation had not got power to set up such a competing business and use the rates for carrying it on, rates which were paid by the very people they were competing with.

Mr. Justice Neville said that it appeared to him that there were two questions before the Court. First of all could the Corporation do these things, and secondly, if they could, could they pay for them?

Mr. Cassell said that was so, so far as exercising any powers under the Electric Lighting Acts was concerned, but it seemed that defendants raised something beyond. Supposing that, apart from any statute, defendants had a general right to carry on business then he (counsel) contended that they could only throw on the local rate the expenses incurred under the Act, and they had no power to pay for anything that was not authorised by the Act.

Mr. Danckwerts, K.C., for defendants, said he was not going to rely upon anything that was outside the statutes.

Mr. Cassell submitted that the words "necessary and incidental" as used in the 1882 Act meant necessary and incidental to the supply of electric current. He relied on the absence in the Act of any such provision as was found in the Gas Works Clauses Act of 1871. Sec. 38 of that Act contained a right to supply fittings that were the property of the consumer, but the fittings and meters were the property of the supplier. In the Electric Acts a clear distinction was drawn between the user and supplier. The Electric Act contained words that clearly showed that if the fittings of the consumer were of such a character that the electricity was being wasted that suppliers could refuse a supply, but could not go on the premises of the consumer and control the fittings. They had no control over the fittings on the premises, and the statute did not give them power to put in their own fittings.

The first witness, Mr. Taylor, said his house was wired by the Corporation. The installation included the supply of a hat rail, mahogany blocks, lamps, bell-push, shades, &c. For his garden and stable he paid rates to the Corporation, but for the house he paid rates to the parish of Oadby. There were no electric fittings except in the house, though the electric cable ran through the garden.

Mr. Robert T. Smith, who had made an inspection of defendants' works, gave a number of instances of the Corporation supplying fittings. They had supplied the workhouse infirmary, which was outside their area. They not only supplied bells but also the chemicals for them.

Mr. Danckwerts said his clients claimed the right to supply everything connected with electricity.

Witness, continuing, said he saw nothing to indicate that only persons using the energy would be supplied with fittings. The electrical and gas departments were in separate rooms, but he did not admit that there was no entrance to the electrical department without going through the gas department.

Mr. R. I. Crowford also gave evidence to similar effect.

Mr. Waters, electrical contractor, said that the contractor's business carried on by defendants was a distinct business, and was well known in the trade.

Mr. L. G. Tate explained the usual method of giving supply and the connecting up of the supply cables at consumers' terminals. The trade of wiring or putting in an installation was a separate business, he said, from that of the supply of electricity.

In cross-examination witness said that the Electrical Contractors' Association did not guarantee its members against the costs of actions. There was an arrangement between the members themselves for guaranteeing against loss. He did not know anything about a guarantee with reference to the costs of this particular action. Electricity supply undertakers were, by Act of Parliament, bound to keep a consistent pressure within certain limits.

Mr. W. R. Rawlings also gave evidence as to the wiring of consumers' premises. He said the terminals were usually reckoned to be at the main cutout, and then the supply could be cut off by the withdrawal of the tubes. Installation work was regarded as perfectly distinct from the business of supply.

Mr. Danckwerts, for the defence, said that from 1898 to the present time the course adopted by the Corporation had been the same, and was entirely consistent with the resolution they passed on May 9 that year and the letter that they then wrote. That letter clearly expressed the intention of the Corporation only to do wiring and only to sell apparatus and fittings to such premises as were taking or were going to take their supply of electricity from the Corporation. That was what they had done according to the evidence, and that was what they claimed they had a right to do. For 12 years the Corporation had adopted that attitude,

Digitized by Google

and when he drew attention to the Acts of Parliament and the authorities the Court would find they authorised the taking of that attitude. He relied upon the doctrine that had been stated in various ways in the numerous authorities that a company formed for the purpose of supply had power to do everything incidental and necessary to such supply. The Acts employed compendious language, but he hoped to show that the compendious language did cover a supply right up to the point at which the gas or electricity, as the case might be, was consumed. It must continue right up to the point of consumption, because until it got there the supply was not complete. If the supply was not complete until you got to the point of consumption then everything that was used for getting to the place of consumption was part of the supply. Whether you called it an electric line apparatus or fittings did not matter. Sec. 10 of the Act of 1882 gave power to do all such things as were necessary for the supply, and to enter into contracts for the purpose, why, therefore, should the Corporation not be entitled to enter into contracts to supply fittings, which were certainly incidental and necessary to the supply, because they were necessary to enable the consumer to utilise the supply. Until one got the light or heat or whatever it was that was required the supply was not complete. He contended that it had been proved definitely that everything the Corporation had supplied had been supplied in connection with their supply of electrical energy. He did not contend that they had any right to supply telephone wires or anything of that sort, nor was he going to contend that they had any right to supply electricity outside the borough in a general way. He should contend, however, that the Court would not interfere by way of injunction in the exercise of its discretion, that they had not got the proper parties before the Court to enable it to grant an injunction, and that the Act of 1909 contained provisions that enabled a Corporation to supply outside their area with the sanction of the Board of Trade. The Board of Trade had been approached by Leicester Corporation, and while they declined to make a general order authorising a supply outside the area they said they would consider any specific instance.

Mr. CASSELL pointed out that he was not asking for any injunction in respect of supply, but only in respect of fittings.

Mr. DANCKWERTS said then he need not pursue the matter further. He submitted that all the evidence given as to the supply of fittings were instances where they were supplied to people who were taking a supply within the borough area, and it was thought they were required in connection with that supply.

Mr. JAMES SWINBURNE said that the electric supply made a complete circuit and was always under pressure, and the pressure must be kept steady within a small margin. He explained the methods of measuring electric current and the method by which it passed through the meter. Any leakage up to the meter would be the concern of the supply company, and any leakage beyond the concern of the consumer.

For the defence, Mr. J. J. P. BARKER, manager of the Corporation's electric fittings department, said that the Corporation's showrooms were separated from the stores by a yard, and if anyone asked for an electric lamp or anything of that sort it would have to be fetched from the stores. Wiring had been done by the Corporation for people who did not take their supply from them, but it was a long time ago and it was done very seldom. The Corporation had done bell wiring, but that was usually when they were called in to repair wires, and while doing the other wiring they did the bell wiring as well. They were not now doing bell wiring, and if they were asked about bell wiring they referred the applicant to a contractor. He had never put in any telephones or telephone wires, but the work in connection with the Corporation's telephones and wires in their own buildings was done by the Corporation's own men. In his opinion, it was important that premises should be securely wired, and that the fittings should be perfect. He had known instances of the wiring being imperfect on the premises of persons who took current from the Corporation. The Corporation always tested the wires before they were used, whether the wiring was done by themselves or not. Failures often occurred on Saturday afternoons and holidays, when, he assumed, most business premises would be closed and when, therefore, it would be essential to apply to the Corporation.

In cross-examination, he said that so far as he knew it was not the custom to ask their customers to make any declaration. Customers just asked for what they wanted and did not say what they wanted it for. The showrooms had ordinary shop windows in which were displayed water heaters, cooking utensils, &c. The Corporation had put in fittings for one firm to the value of over £500, who were not consumers of their supply. That occurred 15 years ago, but the firm had not taken a supply of energy from the Corporation. The Corporation men never went on premises of people not taking a supply from the Corporation mains unless specially authorised to do so by Mr. A. Colson, their late manager. When usual business premises were closed it was necessary to call upon the Corporation in the event of failure, and he did not know that there were electrical contractors always ready to do the necessary work.

The case for the defence having concluded, Mr. CASSEL, in replying on the whole case, submitted that the Electric Lighting Act of 1909, which had only recently come in force, was absolutely destructive of the position taken up by the Corporation. It extended the rights under the old Acts, and if the arguments for the defence were well founded no extension would have been necessary. It was argued that under the old Gas Acts supply terminated at the burners, or point of consumption, but the Gas Acts and Electric Lighting Acts in that respect were quite distinct. The Gas Acts provided for a supply of fittings, but the Electric Lighting Acts did not refer to electric fittings at all. The word supply was used both in the Electric Lighting Acts and in the Gas Acts. In the Gas Acts no doubt it meant supply up to the point of combustion, but in the Electric Lighting Acts it was expressly defined as being a supply up to the consumers' premises. In the Gas Acts there was power to charge for various things, but in the Electric Lighting Acts there was only power to charge for the supply and for meters. Even assuming that the Corporation were entitled to do wiring on premises which they supplied with current, counsel submitted they were not entitled to extend their undertaking to the sale of the numerous articles they were supplying.

His LORDSHIP thought that they might be considered as things incidental to the supply.

Mr. CASSELL submitted that such a sale was merely keeping a shop.

At the conclusion of the arguments his lordship said he would consider his decision.

Affairs of an Electric 'Bus Co.

On Friday last before Mr. Justice Swinfen Eady, the action of the Reorganisation Control Synd. (Ltd.) v. the International Motor Traffic Synd. (Ltd.) and the Brighton, Hove & Preston Omnibus Co. (Ltd.) was mentioned on a motion for an injunction to restrain defendants from parting with or disposing of eight electric omnibuses or parts of same.

Mr. WARD COLDRIDGE said the International Co. had already parted with the 'buses to the Brighton Co., and therefore he asked for no relief against the first named defendants.

Mr. ASHTON CROSS, for the Brighton Co. undertook that the omnibuses should not be delivered up to any other persons than plaintiffs without giving them seven days' notice.

All the parties consenting, his Lordship directed, with a view to a speedy trial of the action, that plaintiffs should deliver the statement of claim within seven days, and that the defence should be lodged within ten days thereafter.

"Z" Electric Lamp Mfg. Co. (Ltd.) v. Marples, Leach & Co. (Ltd.)

This case came before the Court of Appeal (Lords Justices Farwell and Kennedy) on Saturday on defendants' application to allow further evidence on the hearing of their appeal from a judgment of Mr. Justice Parker on plaintiffs' claim, and for an injunction to restrain the alleged infringement of Johnson's patent No. 21,654 of 1906, which related to improvements in the manufacture of filaments for incandescent electric lamps. The judgment was set out in THE ELECTRICIAN for March 11 (p. 905).

Mr. T. TERRELL, K.C., on behalf of defendants, said he and Mr. A. J. Walter, K.C., for plaintiffs, had agreed that their lordships should make no order upon the motion that day, but that it should stand over until the hearing of the appeal, when their lordships would be in a position to know whether further evidence should be heard or not.

Their lordships decided accordingly.

Donnersmarckhutte Oberschlesische Eisen & Kohlenwerke A.G. v. Electric Construction Co. (Ltd.)

In the Court of Appeal (Lords Justices Farwell and Kennedy) on Saturday, Mr. J. A. Walter, K.C., moved on behalf of plaintiffs, who are appealing from the decision of Mr. Justice Parker (reported in THE ELECTRICIAN for March 4, p. 846) that the notice of appeal which was delivered on May 31 might be declared a proper notice, or alternatively plaintiffs asked that if the notice of appeal was held to be bad, the time might be extended.

Lord Justice FARWELL said that he found the notice of appeal was two days out of time, and asked Mr. Bousfield, K.C. (for defendants) whether he opposed the application.

Mr. BOUSFIELD said he saw no reason to anticipate that the judgment of Mr. Justice Parker would be reversed.

Lord Justice FARWELL said the Court would extend the time as asked, the costs of the motion to be costs in the appeal.

Price Bros. v. Cuban Telephone Co. and Others.

This action, in which plaintiffs seek to restrain Messrs. Chaplin, Milne, Grenfell & Co. from parting with and the Telephone Co. from receiving sums that had come to their hands in respect of 5 per cent. first mortgage bonds of the Telephone Co., was mentioned to Mr. Justice Parker again on Friday last.

Mr. TOMLIN (for Messrs. Chaplin, Milne, Grenfell & Co.) said that as soon as the undertaking was given the previous week his clients sent out a circular letter to persons interested whose address they knew stating the terms of the undertaking, and he was quite prepared to give a similar undertaking in all the actions until trial.

Mr. H. E. WRIGHT (for the Telephone Co.) said that he had no objection to the undertakings being given if the costs of the motions were reserved, but he desired to protest against this multiplication of motions, which he submitted ought never to have been brought.

His LORDSHIP said all he could do was to accept the undertaking in the actions now before him, and reserve the costs of the motion. He intimated his view that no further motions ought to be made.

Tungsten Lamp Patent Litigation —In reference to the litigation as to the Tungsten lamp patents we have received the following communication from Messrs. G. M. Boddy & Co.: "We are writing to request you to invite anyone attacked to put themselves at once into communication with our solicitor, Mr. Jonathan E. Harris, 95, Leadenhall-street, E.C., who is defending the action on our behalf with the approval of the Messrs. Philips Metallic Glow Lamp Works (Ltd.)."

Watertube Boiler Litigation.

We have received a communication from Messrs. Edwin Danks & Co. (Oldbury) (Ltd.) in reference to the action brought by Messrs. Babcock & Wilcox (Ltd.) against the Water Tube Boiler & Engineering Co. (Ltd.) and E. Danks & Co. (Oldbury) (Ltd.) and reported on p. 365 of our last issue. As the proceedings were sufficiently reported in our last issue, and as we have been informed that fresh actions by Messrs. Babcock & Wilcox are pending against the defendants, we consider it undesirable to refer to the matter further at this stage.

PARLIAMENTARY INTELLIGENCE.

LONDON COUNTY COUNCIL (TRAMWAYS AND IMPROVEMENTS) BILL.

A Select Committee of the House of Commons, presided over by Mr. A. W. Soames, commenced the consideration of this Bill on Thursday last.

Mr. ERSKINE POLLOCK, K.C., said the proposed expenditure was £931,335, and the works included a double line of tramway from Brixton to Herne Hill, via Effra-road and Dulwich-road, and a line from Effra-road, along Water-lane to Norwood-road. Owners and occupiers of premises in Effra-road opposed the scheme.

Mr. A. L. C. FELL, chief officer of the L.C.C. tramways, said the line would be of advantage to the public, as it would afford alternative facilities for getting from Norwood to Victoria.

Mr. Pollock dealt with the proposed extension of the tramway in Tooley-street from the present terminus to a point near London Bridge.

Mr. M. Fitzmaurice, chief engineer to the L.C.C., said the Deptford line would be worked electrically in a few months, and the proposed continuation would cost £5,500.

London Electric Supply Bill.—This Bill was read a second time in the House of Commons on Wednesday.

MUNICIPAL, FOREIGN & GENERAL NOTES.

APPOINTMENTS VACANT AND FILLED.

Applications are invited for the position of secretary in the Birmingham Corporation electric supply department. Applicants should have had a sound commercial training in some large mercantile or manufacturing concern, and a certain amount of technical knowledge in connection with electricity supply is also required. Salary £600 per annum. Applications to the city electrical engineer, Mr. R. A. Chattock, M.I.E.E., 14, Dale End, Birmingham, by July 1. See also an advertisement.

Applications are invited for the vacant position of assistant lecturer and demonstrator in the physics department of the Technical School, Sunderland. Salary £150 per annum. Applications to the secretary to the Education Department, Mr. T. W. Bryers, 15, John-street, Sunderland, by Tuesday, June 21. See also an advertisement.

A first-class electrical engineer is wanted, with experience in the design of c.-c. machinery. See advertisement.

An electrical engineer is required for an electricity undertaking at Kandy (Ceylon). Commencing salary £350, with furnished bungalow. Five years' agreement, free passage out and home. See an advertisement.

A chief electrical engineer is wanted for an electric power station in the Federated Malay States. See an advertisement.

The governors of the Technical Institute, Loughborough, invite applications for the position of lecturer in engineering subjects. Preference will be given to candidates further qualified to teach mathematics or science. Commencing salary £120 per annum. Particulars from the director of education, Mr. W. A. Brockington, M.A., 33, Bowling Green-street, Leicester.

The Council of the University of Manitoba, Winnipeg, Canada require a lecturer in electrical engineering. Salary $1,500 a year. Applications to the Registrar by June 25.

Professors of engineering, chemistry and mathematics and physics are required for Queensland University. Salary, in each case, £900. Applications to Agent-General for Queensland, London, by Aug. 31.

Watford Council require an assistant electrical engineer. Salary £120, rising to £170. Forms from the Electrical Engineer.

A junior shift engineer is required in Wednesbury Corporation's electricity department. Commencing wages 30s. per week.

At Wednesday's meeting of the Electricity committee of the new county borough of Stoke-on-Trent the appointment of an electrical engineer to take charge of the several electricity undertakings in the federated borough was considered. Applications were received from the managers of the four works formerly carried on by the Councils of Hanley, Burslem, Stoke and Longton—viz., Messrs. C. H. Yeaman (Hanley), A. Bremner (Burslem), P. J. S. Tiddeman (Stoke), and W. Langford (Longton). The committee decided to recommend Mr. Yeaman for the appointment, the final voting being between Mr. Yeaman and Mr. Tiddeman.

Mr. Frank E. Frampton was recently appointed engineer and manager of Paignton Electric Light and Power Co.

Mr. F. H. Hummel, M.Sc., A.M.Inst.C.E., lecturer in civil engineering at Brimingham University, has been appointed professor of civil engineering in Queen's University, Belfast.

Mr. W. H. Hemer, of the Birmingham Technical School, has been appointed teacher of engineering at the Durban Technical Institute.

Accrington.—Haslingden Corporation are considering the terms submitted by Accrington for the supply of electric current to Haslingden on a seven years' agreement.

Acton.—At the meeting of the Council last Friday it was decided, by 12 votes to 10, to hand over the Council's electricity undertaking to the Metropolitan Electric Supply Co., subject to a satisfactory agreement being arrived at. A committee has been appointed to negotiate the terms. It is suggested that the company shall take possession under a 37 years' lease, and pay the Council's loan charges.

Aldershot.—An inquiry will shortly be held into the Council's application for sanction to borrow £2,000 for extensions of the electricity undertaking.

Bexhill.—The assessment of the electricity works has been reduced on appeal from £2,000 to £1,600.

Bournemouth.—The Council are considering the question of the appointment of an electrical inspector.

Dover.—The electric supply mains are to be extended to Alkham.

Ealing.—The electrical engineer (Mr. J. D. Knight) has been empowered to give a free supply of current to local tradesmen for exhibiting electrical appliances at the Suburban Home Exhibition in September.

East Ham.—As Wanstead Council decline to allow East Ham to supply electricity (under sec. 6 of the Electric Lighting Act, 1909) to premises belonging to West Ham Guardians within Wanstead district, East Ham Council will ask the Board of Trade to make an order for the supply being given to the premises.

Electric Power in South Africa.—A recent issue of the "South African Mining Journal" states that Messrs. Harper Bros. & Co. are considering a proposal for the erection of a new power station in the Kroonstad coal mine district, near Klerksdorp, and the transmission of electrical energy to Kimberley, Koffyfontein, Jagersfontein, Bloemfontein and Kroonstad, for supplying power for mining, pumping, tramways, lighting and general power purposes. Messrs. Harper Bros. are reported to be satisfied that such a power station would enable Kroonstad to effect a saving of at least 25 per cent. upon the present cost of generating power.

Fire.—On Saturday afternoon last a fire occurred at the Rosyth Naval Base which destroyed the electric power house.

Fire Alarms.—The leading fire insurance offices announce that discounts up to 10 per cent. are allowed in most cases on fire insurances where approved fire alarms are installed in accordance with the rules of the fire office, and there is also a notification made that shops occupied by furniture dealers, haberdashers, drapers, makers of and dealers in mantles and upholsterers, which are rated at over 5s. per cent., are now allowed 5 per cent. discount if these shops are lighted (even with the exception of the living rooms) wholly by the electric light. These considerable discounts allowed by the insurance offices should prove a useful weapon with which to tackle the gas interests in all large cities and towns.

Fulham (London).—Alterations to sub-stations to meet the requirements of the regulations under the Factory and Workshop Act, 1901, are to be carried out at a cost of £823.

Gillingham.—The Council have applied for sanction to a loan of £3,500 for mains extensions, services, &c.

Goole.—Mr. J. W. Speight has intimated to the Council that he proposes to apply for a provisional electric lighting order.

Hendon.—At the expiration of the contract with the Gas Light & Coke Co. in September next, 27 lamps are to be excluded from the new contract which Kingsbury Council desire should be lighted by electricity. Hendon Council will supply current and maintain these lamps at the rate of £3 per lamp per annum.

Hereford.—An inquiry was held last week into the application of the Council for sanction to borrow £3,000 for extensions of the electricity undertaking.

It was stated that £1,500 of the loan was required for mains and the balance for services. The total capital expended was £47,425 and the mount sanctioned £46,338.

Digitized by Google

The Inspector (Mr. H. Ross Hooper) suggested that an overdraft of £425. 11s. 10d. should be paid out of revenue. There were certain items in the capital account for which the L.G. Board did not sanction loans, and he would point that out to the Board. The cost of the provisional order and miscellaneous items amounted to £383. 18s. 9d. Deducting that from the overdraft of £425. 11s. 10d., the balance was £41. 12s. 3d.

The Town Clerk said the Inspector's suggestion had come rather as a shock, because previous expenses in that connection had been allowed.

The Inspector said the difficulty had been that in the past they had pooled all their loans, and it was never intended that they should pool their loans. He suggested that the amount of the loan asked for should be increased, and if the Council liked to forward a resolution asking for an additional £500 it could be sanctioned without further inquiry.

Hornsey.—Stroud Green school is to be wired.

Huddersfield.—Linthwaite Council have accepted the Corporation's offer of £4,000 for their tramways, subject to the Corporation taking over the contracts entered into by the Council and laying a double line from Pinfold to Slaithwaite.

London County Council Tramways.—It is stated that the opening of the line from Woolwich to Eltham is postponed, owing to delay in delivery of a portion of the equipment.

To meet the objection of the Admiralty to the usual earth return, which, it was urged, might have interfered with instruments at Greenwich Observatory, the expedient of equipping each car with two trolley poles through one of which the return current is transmitted to a return wire, has been adopted on this section of the tramways.

The line from Streatham, via Mitcham-lane, to Tooting is expected to be opened in about six weeks.

At the meeting of the Council on Tuesday the Highways committee recommended that three months' notice be given to the Metropolitan Electric Tramways (Ltd.) requiring them to sell to the L.C.C. their tramway in the Seven Sisters-road, between Blackstock-road and Green Lanes (Manor House section).

Market Harborough.—The Council have applied for an extension of time for carrying out their provisional order.

Melbourne (Derbyshire).—The Council are in negotiation with the Melbourne & District Electric Light & Power Co. in regard to street lighting.

National Electrical Manufacturers' Association.—The next committee meeting will be held at Balfour House, Finsbury-pavement, London, E.C., on the 21st inst., at 2:30 p.m.

Newport (Mon.).—An inquiry was held last week into the application of the Corporation for sanction to borrow £31,255 for extensions of the electricity undertaking.

The town clerk (Mr. A. A. Newman) stated that the demand for current was increasing at such a rate that it was necessary to carry out extensions. Mr. C. P. Sparks, who had been consulted by the Corporation, had recommended certain things, including the installation of new plant, and that there should be a centralisation of the generating plant at the present power station in Corporation-road. The loan was required for machinery for the power station in Corporation-road, machinery in substitution for the old plant at Llanarth-street, for cables to convey current from the Corporation-road station to Llanarth-street, and to distribute current from Llanarth-street to various parts of the town, and for the supply of sub-station plant to reduce the voltage.

The engineer and manager (Mr. H. Collings Bishop) said it was the intention to ultimately make the Llanarth-street works a sub-station. They had had an inquiry for a supply of 1,460 H.P. from one consumer.

On the resumption of the inquiry on Saturday some evidence in opposition was given on behalf of the Ratepayers' Association.

The Inspector said he had no intention of tying the town up too tightly, but it was necessary to be careful about the expenditure, because it was obvious that the undertaking was over-capitalised.

The Town Clerk said he could not admit that there had been any reckless expenditure.

Mr. H. Collings Bishop: Not for many years. And it was due in the past to a large extent because there were two systems.

Obituary.—The death took place on June 3 of Mr. Frank Wright, consulting engineer. Deceased was the inventor of a "penny in the slot" gas meter and (jointly with Mr. W. Mackie) of a glass-blowing machine. In the early days of electric lighting Mr. Wright was assistant to Mr. G. Lane-Fox.

Oswestry.—The Watch committee have been instructed to reconsider the tenders for public lighting, especially as the local electric lighting company has offered to light 44 lamps at 7s. 6d. per lamp per annum less than the gas company.

Patent Legislation.—A Patents Bill will shortly be brought up for consideration in the Second Chamber of the States General of the Netherlands.

Under the bill patents can be granted for new or improved inventions, the person first sending in an application being considered to be the inventor, and applicants must be resident in Holland or establish their domicile at the address of a proxy in the Netherlands. The application is to be published in a "Gazette" issued by the Industrial Property Office, and during the following six months the specification, &c., may be examined by the public and opposition entered. At the end of this time the Patent Council shall decide whether the patent shall be granted. Three months are allowed for appeal. After three years from the granting of the patent, the Patent Council may grant compulsory licences in the interest of the Netherlands, her colonies or possessions, compensation being paid to the patentee by the persons receiving the licenses. A patent is to be granted for 15 years, but the Patent Council may repeal a patent if within five years from the date on which it was granted the patentee (or a holder of a license granted by him) has not a bona fide establishment for working the patent in the Netherlands or her colonies. A patent can be expropriated if public interests so require.

The British Consul at Bangkok, Siam (Mr. W. N. Dunn), says there is no Siamese patent law, but holders of British patentees may exhibit copies of their patents at H.M. Consular establishments in Siam, or publish a notice in the "Bangkok Times," the "Siam Observer," or the "Bangkok Daily Mail" of the ownership of a patent, and sec. 59 of the Siam Order in Council, 1906, provides that "any act which, if done in the United Kingdom or in a British possession, would be an offence against the then existing British Patent Acts, or any statute amending or substituted for them, shall, if done by a British subject in Siam, be punishable as a grave offence against the Order in Council."

Personal.—Col. R. E. Crompton, R.E., has been appointed consulting engineer to the Road Board, and Mr. Rees Jeffreys secretary.

Public Electric Lighting in Hammersmith.—In a recent communication to the "Daily News" the chairman of the Hammersmith Electric Lighting committee (Mr. Arthur R. Cracknell) states that his committee has lately converted all lamps in streets where low-tension mains are laid from gas to electricity, with the highest and best results, both from efficiency and cost.

The electricity undertaking has taken over the street lamps at the price per post the borough was paying for gas, and in place of the ordinary gas mantle light are giving 100 watt Osram lamps. This light, being far better than gas lighting, has given the highest satisfaction to the inhabitants. "I have no hesitation in stating (Mr. Cracknell proceeds) that public lighting by electricity, when supplied on a proper basis, at a reasonable price, is far cheaper and better than gas."

St. Anne's-on-the-Sea.—An unopposed inquiry was held last week into the Council's application for sanction to borrow £3,000 for extensions at the electricity works, including an economiser and a new chimney shaft.

Spain.—The Spanish Public Works Department have granted concessions to the Sociedad Anonima Tranvia de Cadiz á San Fernando y Carraca for the construction of an electric tramway from Cadiz to San Fernando and Carraca, and to the Sociedad Nueva Montana for the construction of an electric tramway in the vicinity of Santander.

An application has been lodged on behalf of the Compañia Madrileña de Urbanización (Madrid) for a concession for the construction and working of a combined steam and electric tramway in the vicinity of Madrid.

Stretford.—Mains are to be extended to supply current to 140 houses and some shops of Mr. H. M. Emery in Old Trafford.

Sunderland.—At the last meeting of the Corporation the chairman of the Electricity and Lighting committee, Ald. Bruce, referred to the new agreement with Messrs. Laings.

During the period when the company was in liquidation temporary arrangements were made with the liquidator. An agreement had now been drawn up to be in force for 15 years.

With regard to the annual report, Ald. Bruce said their engineer (Mr. A. Blackman) deserved every commendation for the way in which he had grappled with the serious problem since he came to the town. It was very creditable that he had been able to place Sunderland in a very favourable position as regarded works cost. They were now bracketed third with Bradford on the list of towns having the lowest works cost. With regard to total cost they stood sixth on the list.

Swansea.—Messrs. Vivian & Sons, who now take current from the Corporation to the extent of about £1,680 per annum, notify that they propose to put down their own plant.

Sweden.—H.M. Minister at Stockholm reports that both Chambers of the Swedish Legislature have agreed to the Government's proposals to establish an electric power station at the Porjus waterfall and to convert to electric traction the State frontier railway in the north of Sweden. These schemes, with the construction of a railway from Porjus to Mount Gellwara, are estimated to cost 21,500,000 kroner (£1,194,500).

Walsall.—Extensions of the Birchills tramway depot are to be made at a cost of £2,000.

West Ham.—The Council have recently entered into a number of agreements for supply of current, including Messrs. J. Knight (Ltd.), the Anglo-Continental Guano Co., Savill Bros. (for Taplow's bottling stores) and the New Oil Refining Process (Ltd.).

Whitwood.—The Council have entered into an agreement with the Yorkshire Electric Power Co. for the supply of electricity in bulk.

Wireless Telegraphy—It has been announced from Liverpool that the experiment which was recently made by one of the principal fishing trawler-owning companies of Hull to utilise wireless tele-

Digitized by Google

graphy on their steam trawlers has not proved successful and has been abandoned.

Wireless Telephony.—In a short note in our last issue, page 368, we referred to Mr. Raymond Phillips' "wireless controlled airship" as having been constructed at New Passage, near Bristol. We are informed by Mr. Phillips that this is an error, as his airship was designed and constructed by him at his private residence in Liverpool.

Woolwich.—The Council have consented to West Ham Corporation supplying electricity to the Port of London Authority in North Woolwich on payment of £40 per annum.

Workhouse Lighting.—Portsmouth Guardians have decided to extend the workhouse infirmary, and the new wards will be lighted electrically.

Power plant is to be installed at the Bedford workhouse laundry.

Atcham (Salop) Guardians are considering the question of adopting electric lighting at the workhouse.

York.—The Board of Trade inspection of the two final sections of the municipal tramways took place on Friday. The lines were then opened for traffic.

Electrical Contractors' Association.—The annual dinner of this association took place at Edinburgh on Monday, the retiring president (Mr. Wm. Finlay) in the chair.

Mr. J. D. GIBSON proposed "The Electrical Contractors' Association." He said he appreciated the value of an association like that. It could do nothing but good, not only in promoting the good feeling which they all wished to prevail in all their respective lines of business, but in establishing and maintaining the highest possible standard of work, which, he was sure they would agree with him, was best for the man who paid, for the man who saw the work through, and for the contractor.

Mr. G. HARLAND BOWDEN (president), in responding, said the association had an ambitious programme. Some of the schemes suggested at their meeting that day were far-reaching, and if carried through would have important effects. He referred to the proposal to consider the desirability of bringing into line every industry connected with the electrical industry. The association was considerably stronger than a year ago.

The annual general meeting of the association was held in the afternoon, Mr. W. R. Rawlings (London) presiding.

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Bury (Lancs.)—The accounts of the electricity supply department for the year ended March last show capital expenditure £117,053 (increase £23,460). The total amount raised by loans is £119,372, of which £19,586 has been extinguished. The sinking and reserve funds are £5,814 and £10,355 respectively.

The year's revenue was £18,600 (against £16,733 in 1908-9); total working expenses £8,269 (against £7,742); interest absorbed £3,003 (£2,709) and sinking fund £3,759 (£3,368); total costs, including capital charges, being £15,031 (£13,819) and net profit £3,569 (£2,914). Working expenses were 0·51d. (0·57d.) per unit, and total costs (including capital charges) 0·92d. (1·03d.); but, in consequence of average revenue being reduced to 1·14d. per unit (against 1·25d.) the net profit was the same as last year (0·22d. per unit). £1,000 (£1,500) has been allocated to relief of rates and £2,569 (£1,414) to reserve. 4,048,373 units were generated; 1,771,718 (1,623,603) supplied to tramways and 2,077,624 (1,536,943) to private consumers. The total maximum demand was 2,065 kw. (1,695 kw.) and the load factor 21·6 (21·6). There are 565 consumers with 107,313 equivalent 8 c.p. lamps connected, increases of 27 and 16,565 during the year, compared with 28 and 15,098 in previous year. The increase of motors connected was 39 (479½ H.P.), making a total of 314 (2,506 H.P.).

The total capital expenditure of the tramways department is £281,146, in addition to capital spent on tramways leased and worked by the Corporation. The year's revenue was £59,820 and total working expenses £36,294 (=5·868d., against 5·833d. per car-mile), and the net profit was £2,636. Total revenue per car-mile was 9·14d., working expenses were 5·868d., and the average fare per passenger was 1·16d. 12,333,902 (11,632,126) passengers were carried and 1,566,768 (1,513,580) car-miles run.

Croydon.—The total revenue of the tramways department for the year ended March 31 was £84,847, including £83,030 from traffic receipts.

The working came to £63,034, leaving gross profit £21,763. After crediting £909 for bank interest and paying £8,084 for interest, £7,371 for sinking fund and £211 for income tax, there was a net profit of £7,006. 18,705,604 passengers were carried (against 16,262,290) and the car-miles run 2,253,710 (against 1,945,645).

Huddersfield.—The accounts of the tramways department for the year ended March 31 show total receipts of £90,829, including £87,420 traffic revenue.

Working expenses were £47,467 (including £21,912 traffic expenses, £7,512 for power, £13,915 for general repairs and maintenance and £4,128 general expenses), and the gross profit was £43,362. After paying interest and sinking fund charges, placing £12,250 to reserve and applying £2,062 to relief of rates, the balance (£6,807) was carried forward. 17,925,058 passengers were carried and 2,027,077 car-miles (including 9,588 coal truck-miles) run. 4,516,750 units of electrical energy (1·44 per car-mile) were consumed; and the percentage of working expenses to receipts was 52·26. The capital expended is £408,325. 12s. 10d.

Keighley.—The accounts of the tramways department of the Corporation for the year ended March 31 show total revenue of £9,249, the traffic receipts amounting to £8,994.

Working expenses were £5,724; interest absorbed £1,081 and sinking fund £1,696, leaving net profit £747. 2,125,800 passengers were carried, and 225,347 car-miles run. 270,889 units of electrical energy (1·2 units per car-mile) were consumed; the average total revenue per car-mile was 9·85d. and the total expenses (including power) 6·09d. The capital expended is £46,112, an increase of £31 during the year.

Lincoln.—The accounts of the electricity supply and tramways undertakings for the year ended March 31 were approved by the Council last week.

The year's income of the electricity department was £12,777, and included £7,989 from the sale of current for public and private lighting, £3,826 from power supply and £880 from the tramways department. The total working expenses were £6,284, and the gross profit was £6,493. Dividends and interest on stock came to £2,045, and the annual instalment paid to the consolidated loans fund was £1,945, and the deficit for the year on the tramways was £43. 15s., leaving £2,459 to be transferred to reserve. 1,642,424 units were sold, against 1,718,612, the decrease being due to a drop in the demand (122,741 units) by Messrs. Clayton & Shuttleworth. Notwithstanding the increased use of metal filament lamps there was a considerable advance in the demand for private lighting. The equivalent of 5,481 8 c.p. lamps was connected during the year (against 4,438 8 c.p.), bringing the total connections to 74,253 8 c.p. The total works costs were 0·918d. per unit sold (against 0·899d.) and the total costs (including interest and sinking fund) 1·501d. (against 1·454d.).

The traffic revenue of the tramways department was £6,309, and the total income £6,429. The working expenses were £3,901, and after providing for redemption and interest there was a net deficit of £43. 15s. There was an increase from £731 to £918 (1·12d. to 1·40d. per car-mile) in the expenses of repairs and maintenance, and from £1,370 to £1,478 (2·10d. to 2·26d.) in traffic expenses. The power and management and general expenses showed slight decreases.

Loughborough.—The receipts of the electricity department for the year ended March 31 were £3,300, against £3,285.

Income from the sale of current was £2,862, against £2,329. Total expenditure was £2,447, against £2,738, and the balance was £854, against £547. Interest required £1,467, sinking fund instalment £834 and renewals fund £10, total £2,311. There are 336 consumers (including 34 "free" wired installations and 26 power consumers on hire-purchase system) connected to the mains, representing the equivalent of 26,653 8 c.p. lamps, against 21,804 8 c.p. There are 90 motors, against 69 of an aggregate of 480 B.H.P. against 381½ B.H.P. The works costs were 1·361d. per unit sold, against 1·852d. The capital expended is £32,136, an increase of £232.

Nottingham.—The traffic receipts of the tramways department for the year ended March 31 was £152,495, the total income being £154,936.

Working expenses were £98,163, leaving a gross profit of £56,773. Interest absorbed £16,540, sinking fund £6,930, and instalment for repayment of loans £11,004, leaving a net profit of £22,298, of which £20,550 was devoted to relief of rates and the balance (£1,748) carried to reserve. Capital expended is £613,864, an increase of £232. 34,647,238 passengers were carried and 3,340,549 car-miles run.

Warrington.—The accounts of the electricity department for the year ended March last show capital expenditure £98,269 (increase £3,068).

The year's revenue was £16,818 (against £15,400 in previous year), generation and distribution costs were £9,231 (£9,318), gross profit £7,587 (£6,740), and net profit £1,691 (£943). Maximum load was 1,625 kw. (1,220 kw.), and the number of equivalent 8 c.p. lamps (exclusive of traction load) connected at the end of the year was 106,143 (87,232). Units sold (exclusive of traction) were 2,243,822 (2,064,552). Current supplied for lighting increased by 54,248 units, although many metal filament lamps were substituted for carbon lamps during the year.

Weymouth.—The income of the electricity department for the year ended March 31 was £6,184, and included £4,240 from the sale of current and £1,907 from public lighting.

Working expenses were £2,823, leaving a gross profit of £3,361 to meet interest (£1,760), sinking fund (£1,695), and bank interest (£19.10s.). The net deficit was £113, against a profit of £102 in 1908-9. The total units sold were 392,319. There are 400 consumers, with the equivalent of 28,778 33-watt lamps connected, and the maximum load was 353 kw.

The engineer and manager (Mr. J. H. Bolam) states that the small decrease in revenue (£107) is due to the increasing use of metal filament lamps and to depressed trade. The total working costs were 1·44d. per unit sold, the coal costs were 0·45d. per unit (against 0·6d.), and the total costs were 2·13d. per unit. The prospects for the current year are better.

Digitized by Google

Worcester.—The accounts of the electricity department for the year ended March 31 were presented to the Council last week. The total revenue was £15,764, including £10,738 net from the sale of current.

Working expenses were £6,996, leaving a gross profit of £8,768. After paying interest and sinking fund (£10,169) there was a net deficiency of £1,401. This result is mainly attributed to the loss of revenue from lighting (£1,170) due to the extended use of metal filament lamps. There was an increased revenue from power users of £428 and of £66 from street lighting, while there was a reduction of £634 in costs of production. During the past year 35 new consumers (representing 4,109 30-watt lamps) were connected (bringing the totals to 882 consumers and 76,032 30-watt lamps), against 52 (9,939 30-watt lamps) in 1908-9. The year's output at Powick water-power works was 371,011 units against 497,289. 1,379,056 units were generated at Hylton-road, against 1,304,962. The total costs per unit sold were 0·966d. (against 1·011d.). The total capital expenditure is £146,947, an increase of £1,537.

TRADE NOTES AND NOTICES.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.—The 1910 Edition of the Big Blue Book is NOW READY, price 15s., post free in the United Kingdom, 15s. 9d. The volume brings a great mass of very valuable statistical and technical data quite up to date, and the Directorial Division has been thoroughly revised and amplified up to February 16th.

All branches of Electrical Engineering and Industry are fully treated, and Electro-Financial matters receive every attention in the new volume, which aggregates more than 2,000 pages. The Directory Division is complete and thoroughly accurate, and has been completely revised. The Big Blue Book contains more names of live electrical firms and persons than any other Directory published, and this notwithstanding **that all mere lists of members of Societies and Institutions (so easily and cheaply available) are excluded, as unreliable and of little value for Manufacturers' and Dealers' purposes. The full set of valuable Statistical and Engineering Tables, &c., have been very carefully revised and extended, and are now issued in a handy form. These are included in the 1910 Big Blue Book, making it the most complete work of the kind ever published.**

TENDERS INVITED.

HAMMERSMITH (London) Council invite tenders for supply of l.t. service cable and air-cooled transformer. Specification, forms of tender, &c., from the borough electrical engineer, Mr. G. Gilbert Bell, electricity works, 85, Fulham Palace-road, W. Tenders to the town clerk, Mr. H. Thompson, Town Hall, Hammersmith, W., by 4 p.m. June 22. See also an advertisement.

SHANGHAI Municipal Council invite tenders for supply and delivery (c.i.f. Shanghai) of two 940 k.v.a. two to three-phase step-up transformers, e.h.t. switchgear, e.h.t. underground mains and feeder pillars. Specifications, &c., from Messrs. Preece & Cardew, 8, Queen Anne's-gate, Westminster, S.W., to whom tenders before noon July 5. See also an advertisement.

Tenders are invited by July 6 for the supply of cordless switchboards to the Postmaster-General's Department in SOUTH AUSTRALIA. Tender forms and specification may be obtained at the Commonwealth Offices, 72, Victoria-street, London, S.W. See also an advertisement.

Tenders are invited up to July 27 for supply of a pneumatic tube service to the Postmaster-General's Department at ADELAIDE (S. Australia). Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W. See an advertisement.

Tenders are invited up to Aug. 2 for the supply and delivery of 1,820 private letter box fronts to the Postmaster-General's Department in the States of VICTORIA, QUEENSLAND, SOUTH AUSTRALIA and WESTERN AUSTRALIA. Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W. See also an advertisement.

BELFAST Harbour Commissioners are prepared to receive tenders for the construction, delivery and erection in their electric light station, Abercorn Basin, Belfast, of a direct-coupled steam engine and dynamo, with all requisite accessories. Specifications and form of tender, &c., from the harbour engineer, Mr. W. Redfern Kelly, M.Inst.C.E. Tenders to the secretary, Mr. W. A. Currie, Harbour Offices, Belfast, by June 22.

The Electricity committee of the County Borough of NEWPORT (Mon.) invite tenders for the supply and erection of l.t., h.t. and e.h.t. switchboards. Specifications, &c., from the borough electrical engineer and tramway managers, Mr. H. Collings Bishop, M.I.E.E. Tenders to the Town Clerk, Town Hall, Newport, Mon., by Monday, June 27.

CROMPTON Council want tenders by 10 a.m. June 30 for supply of dynamos and other electrical equipment, including motors, wiring, lamps, &c., for lighting new and present buildings at New Hey sewage works. Specifications from Messrs. J. P. Wilkinson & Son, 301, Cathedral-street, Manchester.

LONDON County Council require tenders by 11 a.m. July 5 for supply of 250 electric tramcar bodies and 250 electrical equipments for conduit and overhead systems. Specifications, &c., from the Clerk.

LONDON County Council want tenders by 11 a.m. June 28 for supply of petrol or electrically-driven fire escape vans. Specifications, &c., from the Clerk.

BIRMINGHAM Corporation want tenders by June 30 for 12 months' supply of stores for their electricity department, including electrical accessories, ironmongery, &c. Particulars from the City Electrical Engineer.

RAWTENSTALL Corporation want tenders by July 1 for permanent way construction and supply of steel poles, overhead equipment, cables, conduits, &c., for a tramway. Specification from the Borough Engineer.

BATLEY Council require tenders by noon June 28 for supply of a battery of accumulators, an automatic reversible traction booster and a battery charging booster. Specifications from Borough Electrical Engineer.

STOCKPORT Electricity and Tramways committees require tenders by noon June 22 for supply of carbon brushes, overhead line material, tubing, ironmongery, oils, &c. Forms of tender from Borough Electrical Engineer.

MANCHESTER Electricity committee want tenders by 10 a.m. June 22 for meters, service cables, motors and starters. Forms of tender from Mr. F. E. Hughes, Town Hall, Manchester.

MANCHESTER Electricity committee also require tenders by June 24 for supply and erection of two 125 k.v.a. three-phase static transformers and h.t. and l.t. switchgear. Specifications, &c., from Mr. F. E. Hughes, Town Hall, Manchester.

TONBRIDGE Council want tenders by July 1 for supply of a Lancashire boiler, economiser extension and pipework. Specification from Mr. M. P. Plunkett, Electricity Works, Tonbridge.

Tenders are required by June 28 for supply of electric light and power plant and wiring at the County Asylum, Knowle, FAREHAM. Specification from the County Surveyor, The Castle, Winchester.

EALING Corporation require tenders by noon July 4 for supply and erection of surface condensing plant, &c., at the electricity works. Specification, &c., from Town Hall, Ealing.

DUNMANWAY (Ireland) Rural Council require tenders by 11 a.m. June 21 for lighting the town by 33 electric, acetylene or oil gas lamps for 10 or 15 years.

NOTTINGHAM Tramways committee want tenders by July 4 for supply of 400 tons of steel rails. Specification, &c., from the City Engineer.

CLACTON-ON-SEA Council require tenders by noon June 22 for supply of 440 yds. 7/18 v.b. armoured twin-service cable.

Tenders are invited for supply of 36,000 incandescent electric lamps to the City of MELBOURNE. Specifications, forms of tender, &c., from the agents for the City Council (Messrs. McIlwraith, McEacharn & Co. Proprietary, Ltd.), Billiter-square Buildings, London, E.C., to whom tenders by noon July 1.

Tenders are invited up to July 19 for supply and delivery of 4,200 telephone sets (as per schedule No. 231) to the Postmaster-General's Department in VICTORIA. Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W.

The Deputy Postmaster-General, BRISBANE (Queensland), will receive tenders until noon June 22 for supply of copper wire and accessories, covered wire, iron wire, insulators, ironwork and sal ammoniac and zinc for batteries. Local representation is necessary.

The Turkish Ministry of Commerce and Public Works want tenders by Oct. 28 (Nov. 10) for a concession for the construction and working of electric tramways in CONSTANTINOPLE and suburbs. A deposit of £13,500 (sterling) is required with each tender. Local representa-

Digitized by Google

tion is essential. Copy of specification (in French) may be seen at 73, Basinghall-street, London, E.C.

The ITALIAN MINISTRY OF MARINE require tenders by 11 a.m. June 30 for the supply of electric lamps and lamp-holders to the arsenals at Spezia, Naples, Venice and Taranto. Upset price 150,000 lire (£6,000). Deposit of 15,000 lire (£600) required to qualify tenders. Only firms on the Government list are generally allowed to tender. Specification may be seen at 73, Basinghall-street, London, E.C.

The Commissione Consultative dei Tranvia Elettrici Municipali, 49, Piazzi SS. Apostoli 49, ROME, want tenders for supply of 50,000 metres (31 miles) of tri-phase cable, 30,000 insulators (4,000 to withstand 30,000 volts), supplies for generating and transformer stations, alternators, transformers, water turbines, 138 miles of copper wire and reinforced concrete standards and iron standards.

The Société Nationale des Chemins de fer Vicinaux, BRUSSELS, want tenders by July 20 for underground cables, and by July 27 for the equipment of a transformer station.

The Austrian State Railways Administration, VIENNA, require tenders by June 27 for equipment of an electric power station at Simmering.

The Ministerio de Fomento, MADRID, will receive tenders until July 30 for the construction of an electric (or steam) strategic railway from Requena to Alcaráz, via Casas Ibáñez and Albacete. The contract is open to Spanish firms only.

The Ministerio de Obras Publicas, SANTIAGO (Chili), will receive tenders until July 15 for the substitution of electric for steam traction on the first section of the Chilian State Railways—from Valparaiso to Santiago and Los Andes.

TENDERS RECEIVED AND ACCEPTED.

West Ham Council received the following tenders for additional plant for the eelctricity works:—

Watertube Boiler, Superheater, Stoker, &c.

Babcock & Wilcox (*accepted*)	**£1,575**
Edwin Danks & Co.	1,052
Clarke, Chapman & Co.	£1,174 & 1.235
Stirling Boiler Co.	1,650

Condensing Plant.

British Westinghouse Co. (*accepted*)	**£1.835.** £2,050 & £1,897
Willans & Robinson	£2,900 & 2,300
Mirrlees-Watson Co.	2,690
Richardsons, Westgarth & Co.	2,200
Worthington Pump Co. (Ltd.)	2,114
W. H. Allen, Son & Co.	1,863

Coventry electricity committee have received the following tenders:—

One 2,500 kw. Turbo-alternator.—British Thomson-Houston Co. (*accepted*), A.E.G. Electric Co., Belliss & Morcom, British Westinghouse Co., Brush Co., Dick, Kerr & Co., General Electric Co., J. Howden & Co., Lahmeyer Elec. Co., J. Musgrave & Sons, C. A. Parsons & Co., Richardsons, Westgarth & Co., Willans & Robinson.

Four Watertube Boilers.—Babcock & Wilcox (*accepted*), Clarke, Chapman & Co., E. Danks & Co., Richardsons, Westgarth & Co.

Two Fuel Economisers.—E. Green & Sons (*accepted*), E. Danks & Co., Goodbrand & Co., Arthur Lowcock (Ltd.).

The following tenders for plant in connection with the electric light and power installation of Edmonton Union have been accepted by the Guardians:—

For electric motors and accessories for laundry equipment, Messrs. G. Harland, Bowden & Co., £240 (with E.C.C. motors); for electric lift motors and fan, Messrs. R. Waygood & Co., £293.

The consulting engineers were Messrs. May & Hawes.

Liverpool Overhead Railway Co. have let contracts for annual stores to the following:—

F. W. Cotterill (Ltd.), bolts and nuts; General Electric Co., electrical fittings and insulating tapes; Manufacturers Agency Co., files, packing and screws; W. & F. Walker, boiler fluid; Burnyeat & Dalzell, general stores; Hellewell & Co., indiarubber, &c.; A. & R. Brown, iron and steel; M. Wilson, ironmongery; C. C. Wakefield & Co., oil and grease; Neale & Co., timber; A. A. Leech, waste and sponge cloths.

Whitehead & Co. A.-G. (Fiume) have secured, after keen competition, the order for the building of a second submarine boat of the Whitehead type for the Dutch Government. This boat will be of the same type as the one ordered from the firm 10 months ago for the Dutch Navy, and will also be built by the "Schelde" shipyard at Flushing.

Poplar (London) Council have accepted the following tenders:—

Westminster Engineering Co., re-winding one stator and fixing new end supports, £170; Bruce Peebles & Co., re-winding stator in solid copper, in place of flexible, re-assemble core, ventilate castings and fix new end supports, &c., £300.

London County Council Education committee have accepted the tender of Johnson & Phillips (at £286) for wiring the Amberley-road school, Paddington; and that of E. Lawrence & Sons (at £346) for wiring the Fairclough-street school, St. George-in-the-East.

Southampton Council have accepted the following tenders:—

Electric Construction Co., motor-alternator; Dick, Kerr & Co., steam generator (Cole, Marchent engine) and surface condensing plant, £8,131; Babcock & Wilcox, water-tube boiler, £1,590.

Whitehaven Council have accepted the following tenders:—

Whipp & Bourne, main switchboard; Stout & Son, pipework; Vulcan Engineering Co., economiser; Callender's Co., cable; and Vaughan & Co., boiler-house runway.

Sunderland Corporation have accepted the following tenders:—

British Westinghouse Co., static transformer for sub-station at Messrs. Doxford's; W. T. Henley's Co., 220 yds. of service cable.

The tender of Johnson & Phillips has been accepted for the wiring of two blocks at the Withington workhouse, West Didsbury, Manchester.

Llandudno Council have placed a contract with the Chloride Electrical Storage Co. for re-plating their storage battery at the electricity works.

Newport (Mon.) Council have accepted the tender of the General Electric Co. for a 60 kw. motor generator, two 400 kw. generators and a booster, at £3,047.

Burnley Council have placed orders with the United Electric Car Co. for two tramcar bodies at £292. 5s. and with Dick, Kerr & Co. for electrical equipment at £264. 8s. 6d. per car.

Clacton-on-Sea Council have accepted the tender of Johnson & Phillips for service boxes, joint box compound, cut-outs and meter boards, and that of Engelbert & Co. for oils.

Croydon Council have accepted the tender of Johnson & Phillips for wiring the hospital extensions at £349.

Stretford Council have accepted the tender of E. Heaton & Sons for a boiler at £1,050.

Walsall Council have accepted the tender of F. & J. Wootton (at £1,150) for erecting a sub-station in Darwall-street.

Faversham Council have accepted the tender of Remark (Ltd.) for forced lubrication of gas engine at the electricity works at £90.

Bradford Corporation have accepted the tender of Thornton & Crebbin for tramway castings at £299. 7s. 6d.

Commonwealth Tenders.—The following tenders have been accepted by the Australian Postmaster-General's Department:—

Victoria.—E. Duckett & Sons, bolts and nuts, £402. 15s.; Danks & Son, 1,000 iron poles and fittings, £875.

N.S.W.—Australian Wireless (Sydney), wireless telegraph stations at Sydney and Fremantle, of 1,250 nautical miles range, £4.150 per station; J. Paton & Co., material for Edgecliff telephone exchange, £125. 6s.

Queensland.—Lawrence & Hanson, 20 miles v.i.r. wire (No. 18 gauge), £195.

Dundee Works committee have accepted the tender of T. C. Keay for wiring St. Paul's (South) Parish Church.

BUSINESS NOTICES

Mr. H. M. Sayers notifies that, as he has accepted a foreign engagement, the business carried on by him at 39, Victoria-street, S.W., has been transferred to his eldest son (Mr. Wm. Higley Sayers), who will carry it on in his own name and on his own account. Matters of account relating to Mr. H. M. Sayers' practice will be dealt with by Mr. A. G. Sayers, C.A. (Messrs. Sayers & Wesson), 19, Hanover-square, W.

We are informed that it has been arranged that Mr. R. B. Slacke, who, as a director of the Key Engineering Co., is known to many of our readers as one of the pioneers of the large gas engine movement in this country, is to join the staff of Messrs. Galloways (Ltd.), who are now manufacturing the Ehrhardt & Sehmer gas engine at their works at Manchester. The Key Engineering Co. will continue to act as agents for the Ehrhardt & Sehmer gas engine and will be prepared, as hitherto, to quote alternatively for these engines made at either the English or German works.

Herr F. W. Busch, of Lüdenscheid, Germany, asks us to state that Mr. A. Brauckmann has ceased to represent him and that he has appointed Mr. E. C. Seear, 16 and 17, Devonshire-square, E.C., his sole agent for the United Kingdom.

Walter O. Rooper and John C. G. McFerran, electrical and consulting engineers, 26, Victoria-street, London, S.W., and Stafford, have dissolved partnership. Debts by Mr. Rooper.

Sale by Auction.—Messrs. Fuller, Horsey, Sons & Cassell have been instructed to sell by auction at H.M. Dockyard, Portsmouth, on

Digitized by Google

July 18 and following days, at 11 a.m., some old and surplus stores, including quantities of scrap brass, old tubes and other scrap metal, scrap steel and iron, lead, old wire rope, electric cable, electric fans, various electrical gear and stores, lathes, engines, &c. May be viewed three days prior to and on morning of sale, and catalogues (6d. each) may be obtained at the Dockyard or of the Auctioneers, 11, Billiter-square, London, E.C. Further particulars are given in an advertisement.

Plant for Sale.—Messrs. Hazell, Watson & Viney advertise for sale some modern electric generating plant, including three Browett-Lindley high-speed engines direct-coupled to Johnson-Lundell generators of 120 kw. each.

Some second-hand electric motors are advertised for sale in another column.

Motor Wanted.—An advertiser in the Midlands requires an electric motor 150 B.H.P., d.c., 250 volts.

Premises to Let.—Messrs. Jubber & Co., 61, Great Portland-street, London, W., have premises in Charing Cross-road to let, suitable for show rooms for electric light fittings, &c.

Patent Development.—The proprietor of patent No. 13,891/1907, for "Apparatus for treating liquids electrolytically," desires to enter into arrangements for exploiting and working the same in this country. Applications to Messrs. Haseltine, Lake & Co., 7 and 8, Southampton-buildings, Chancery-lane, London, W.C.

"A.E.G. Zeitung."—The current number of the "A.E.G. Zeitung" is full of interest. The first article deals with hydro-electric plant, and is the fourth of a series by Mr. Gaze. Other illustrated articles deal with the power station at Havana, the measurement of electric currents, and new applications of electricity.

"Installation News."—The June issue contains some notes on the Holophane system of illumination and on fans and small motors. The article on "Points affecting Conduit Systems" is continued, and there is an interesting article on "Distribution Boards."

Publicity Committee's Literature.—We have called attention on former occasions to examples of the Electric Supply Publicity committee's literature issued in furtherance of the scheme to bring prominently before the public the advantages which electricity offers over gas and other means of lighting, power and heating. The committee are continually issuing illustrated posters, pamphlets, leaflets, &c., many of which have been most effective. We have now received from Mr. H. B. Renwick, secretary of the committee organising the London district, a set of illustrated cards and folded leaflets, which are topical and useful reminders of the facilities of electricity supply in the home, the shop, the workroom, the restaurant, &c., during the hot weather, and we illustrate the frontispiece of one of these leaflets entitled "Electricity and Pure Air," which deals with the ventilation of stuffy places by different types of fans which are neatly illustrated. There is no doubt that this literature, along with other methods adopted for bringing the claims of electricity before the public, will make possible consumers into actual consumers by graphically showing them the means at their command for increasing comfort and improving health. The size of the different items of printed matter, which the trade can obtain through the committee from the offices at Moorgate-court, Moorgate-place, E.C., will be found very useful, and their general circulation must prove advantageous to the industry.

Intensive Illumination.—The inset which will be found in the current issue of THE ELECTRICIAN between pages 388 and 389 is a significant example of the brilliancy of the illumination of public thoroughfares which can be obtained from the latest development of the electric incandescent lamp. There are moments in all industrial developments when the "striking example" is the most effective object lesson, and we think it will be admitted that this is the case in the illustration of the lighting of Queen-street, Glasgow, which the inset is designed to bring to our readers' attention. The General Electric Co., on whose behalf the photo has been taken, with a view of showing graphically the effect of the use of Osram lamps in street lighting, claim this to be one of the finest examples of night photography yet obtained. There are 30 lamps installed in Queen-street, Glasgow, on 23 posts. These consist of 16 100-watt and 14 55-watt lamps. The voltage at Glasgow is 260. The installation was started on April 1, and we are informed that the lamps have burned for 365 hours with the best possible results.

CATALOGUES, &c.

FUSIBLE CUTOUTS.—The British Thomson-Houston Co., of Rugby, are issuing a circular giving illustrated particulars and prices of their fusible cut-outs and fuses.

MOTOR STARTERS.—From Mr. Geo. Ellison, of Birmingham, we have received a copy of sheet No. 181, which deals with the face plate type of "Star-Delta" starters for three-phase squirrel-cage motors.

LIFT AND HOIST TRAVEL METER.—Messrs. Marryat & Place issue a leaflet dealing with a lift and hoist travelling meter made by them, designed to show on a scale each time the lift goes up or down. It should prove a useful check on the energy consumption of the lift.

BANKRUPTCIES, LIQUIDATIONS, &c.

John A. F. Milton, electrician, lately trading at 18, High-street, Crewe, has been adjudicated bankrupt. First meeting of creditors June 23 at the O.R.'s, King-street, Newcastle, Staffs., and the public examination on July 22 at the Petty Sessional Court House, Crewe.

A receiving order has been made against John A. F. Milton, electrician, 258, Hungerford-road (lately trading at 18, High-street), Crewe.

John P. L. Donlevy, consulting electrician, 123, Tulse-hill, London, S.W., has been adjudicated bankrupt.

A first and final dividend of 4½d. is payable at 28, King-street, Cheapside, London, E.C., to creditors of Joseph G. S. Cunnington (separate estate), electrical engineer and contractor, formerly trading with Harry P. Allison, as Laing, Wharton & Cunnington, at 7, Gt. Newport-street, London, W.C.

A first and final dividend of 5s. 9d. will be payable on June 25 at 2, Offa-street, Hereford, to creditors of Robt. E. Walker, electrical engineer, &c., 16, Widemarsh, and Eigne-road, Hereford.

The Typewriting Telegraph Corpn. (Ltd.) is being wound up voluntarily. Mr. C. S. Beale, 72, Bishopsgate-street Within, London, E.C., is liquidator.

A meeting will be held at 28, Baldwin-street, Bristol, on July 12 to receive an account of the winding up of the Unity Motor Electrical & General Engineering Co. (Ltd.)

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned Applications (except those marked †) are not open to public inspection until after acceptance of Complete Specifications. Those marked * are open for inspection 12 months after the date attached to them, if they have not been published previously in the ordinary course. Names within parentheses are those of communicators of inventions. When complete Specification accompanies application, an asterisk is affixed.*

COMPANIES' MEETINGS AND REPORTS.

ARON ELECTRICITY METER (LTD.)—The directors' report for the year ended March 31 states that the net profit, after providing for general charges and depreciation, was £21,117. 17s. 3d., making, with £6,549.8s.1d brought forward, a total available profit of £27,667. 5s. 4d. The directors distributed in December last a dividend of 3 per cent. on the preference shares, absorbing £3,746. 17s. 6d., leaving £23,920. 7s. 10d. to be disposed of. The directors recommend payment of a further 9 per cent. on the preference shares, representing 3 per cent. the remainder of arrears and the full 6 per cent. dividend for the past financial year, amounting altogether to £11,240. 12s. 10d., and a transfer to reserve towards goodwill and patents of £6,000, leaving a balance of £6,679. 15s., out of which it is proposed to appropriate £1,326. 3s. 10d. to pay off arrears of management commission and directors' fees, and to carry forward £5,353. 11s. 2d. By the distribution of this year's profits as proposed, the preference shareholders will have received, apart from their yearly dividend, the residue of the arrears due to them. The board hope that the ordinary shareholders may in the near future participate in the distribution of dividends. The past year's trading has been most satisfactory, the sales having exceeded those of any previous year. The increased demand for the company's products has employed the factories to the full. The taximeter business is progressing satisfactorily in England, Belgium and Austria, though it has not yet contributed to the profits. The transfer books and register of members will be closed from 20th inst. to July 2 inclusive.

BIRMINGHAM & MIDLAND TRAMWAYS (LTD.)—At the meeting on Monday Mr. C. S. B. Hilton said, in regard to the new system of fares which they hoped would improve their revenue, they had not yet had sufficient experience of its working to arrive at any conclusion. There was, however, a very satisfactory improvement in the sale of electricity for power and light. The total number of units sold showed an increase of 38 per cent., the revenue showed an increase of 23 per cent. and the balance of revenue over expenses an increase of 32 per cent. That improvement was being well maintained during the present year, and they had been obliged to order additional plant. They were also interested in the Shropshire Power Co. and in the developments of the very large area of the company, and they looked for a very considerable improvement in revenue when the Shropshire Co. had been able to develop their area.

BRITISH ELECTRIC TRACTION CO. (LTD.)—The directors' report for the year ended March 31 states that the £3,000 5 per cent. perpetual debenture stock and £53,206. 4½ per cent. second debenture stock of the company were purchased in the open market; the issued debenture stocks have been reduced by those amounts, and the difference of £16,383.11s.3d. between the purchase price and the nominal value has been transferred to reserve. The amount of reserve at March 31 was £618,581. 17s. 3d., and this figure will be further increased by £15,000 proposed to be transferred to reserve out of the profits of last year. In addition, reserves amounting to £58,752. 2s. 3d. have been made from time to time out of profits against loss and depreciation of specific assets. The various associated companies have created depreciation and reserve funds of their own, which amounted at Dec. 31, 1909, to £1,175,997. Investments and undertakings stand at £4,997,845. 17s. 4d., and consist of shares and debentures in associated tramway, electricity supply, manufacturing and other companies, Consols and sundry securities and undertakings. The expenditure on and in connection with the new building in Kingsway amounts to £42,036. 18s. 4d. It has been arranged to grant a lease of this building to the British Electrical Federation for 21 years. Expenditure on Acts of Parliament, &c., has increased, and now stands at £26,783. 16s. 3d. It is being written down annually by 20 per cent.

The net profit, after reserving £12,500 against depreciation of undertakings worked by the company, buildings and freehold land, doubtful debts and expenditure on undertakings not proceeded with, and after transferring to reserve the profit of £10,397. 18s. 10d. on sales of investments, is £130,564. 5s., added to £20,203. 10s. 10d. brought forward, making £150,767. 15s. 10d. After deducting interest on the 5 per cent. perpetual debenture stock and the 4½ per cent. second debenture stock for the year (£97,484. 15s. 4d.) there remains £53,283. 0s. 6d., out of which it is proposed to pay a dividend of 3s. per share on the preference shares, amounting to £24,215. 11s., and to transfer £15,000 to reserve, leaving £14,067. 9s. 6d., which the directors propose should be carried forward.

Digitized by Google

This dividend will bring the payment of the full dividend on the 6 per cent. cumulative preference shares to June 30, 1908, and the reserve will be increased from £618,581. 17s. 3d. to £633,581. 17s. 3d. The yield for the past year on the total investments and undertakings standing in the books at £4,997,845 was 2·63 per cent., compared with 2·5 per cent. for the preceding year on £5,037,095.

For some years past the directors have made every effort by increasing fares, eliminating unremunerative services and by similar means to increase the profits of the tramway undertakings, and they have been successful in arresting the steady decline in the receipts per passenger. The directors have during the past year given much time and attention to the examination of various schemes for increasing the net profit on the working of tramways, keeping in view the importance of not increasing the fares to an extent likely to deter traffic. As a result the "Fair Fare" system has been devised, and many of the federated companies have adopted the system. The directors state that during the past few months there has been a marked improvement in the traffic receipts on the tramway undertakings, but there has not yet been sufficient experience of the system to enable them to say definitely to what extent the improvement is the result of its adoption or is due to better weather conditions and improved trade.

The various lighting undertakings in which the company is interested show steady improvement, but owing to the introduction of metal filament lamps the advance in net profits has to some extent been checked. The electrical manufacturing industry is still in a very unsatisfactory condition, and the accounts of the Brush Electrical Engineering Co. for the past year show a loss. With regard to the other branches of the company's operations and particularly the development of new electrical enterprises, the directors feel that opportunities for promoting new tramway and lighting undertakings in this country with a prospect of reasonable profit are rare.

Having regard to the general position of the company the policy by which the directors are guided may be stated as follows: To meet depreciation, the associated companies have made various reserves which amount to £1,175,997; moreover the B.E.T. Co. itself has a reserve of £633,581. 17s. 3d., which is also available to meet depreciation. The increase of these reserves is a matter to which the attention of the directors is constantly given, and while they recognise that the depreciation of assets which has occurred may be in excess of the existing reserves, they consider that it would be incorrect under the existing conditions to make any valuation based upon the present market quotations of the company's own shares and debenture stocks, which in the opinion of the directors show an unduly exaggerated depreciation. They propose for the immediate future to deal with the depreciation as and when its amount is ascertained, and so long as such depreciation continues to transfer to reserve any profits or losses (other than accrued dividends or interest) made by realisation of present investments. The accounts for the year are made up on this principle. They recommend also an annual addition to reserve out of net profits. With regard to the management of the associated companies, an efficient organisation for the administration and working of the various undertakings has been established by means of the British Electrical Federation, and the results show that, compared with other enterprises of a similar kind, the associated undertakings are being economically worked.

GLOBE TELEGRAPH & TRUST CO. (LTD.)—The net revenue of the company for the year ended May 31, after deduction of expenses, amount to £209,117. 17s. 11d., making, with £27,305. 5s. brought forward, £236,423. 2s. 11d. From this there has been distributed £131,085. 9s. in interim dividends, leaving an available balance of £105,337. 13s. 11d. The directors now recommend payment of the following final dividends—viz., 3s. per share (less tax) on the preference shares, making 6 per cent. for the year (less tax), and 5s. 9d. per share net on the ordinary shares, making 5⅞ per cent. net for the year. These dividends absorb £77,656. 8s. 11d. and leave £27,681. 5s. to be carried forward.

R. WAYGOOD & CO. (LTD.)—The profits earned during the year ended March 31 (including £3,159. 10s. 8d. brought forward) amounted to £23,755. 8s. 6d. After paying directors' fees, &c. (£2,800), preference dividend (£8,100), placing £1,000 to reserve, writing £1,090. 3s. off experimental work, and paying interim dividend on ordinary shares (£3,375), the balance was £7,390. 5s. 6d. A further ordinary dividend is declared at the rate of 7 per cent. (making 6 per cent. for the year) (£4,725), leaving £2,665. 5s. 6d. to be carried forward.

NEW COMPANIES, STATUTORY RETURNS MORTGAGES AND CHARGES.

NEW COMPANIES.

LEAKE-SUMNER GUN FIRE CONTROL SYND. (LTD.) (110,104.)—Reg. June 9, capital £1,500 in £1 shares, to carry on the business of engineers, manufacturers of and dealers in apparatus used in connection with electric signalling, &c., and to acquire from H. C. Leake and O. Sumner and turn to account certain inventions relating to gun fire control and improvements therein, &c. Private company. Reg. office, 39, Victoria-street, London, S.W.

TELEGRAPH CONDENSER (LTD.) (110,048.)—Reg. June 7, capital £5,000 in £1 shares, to take over the business of the Telegraph Condenser Co. and to carry on the business of manufacturers of and dealers in electrical apparatus, &c. Private company. First directors, J. A. L. Dearlove and S. G. Brown. Reg. office, The Factory, Vauxhall-street, London, S.E.

STATUTORY RETURNS.

ELECTROPHONE (LTD.)—In return to March 31 capital is £15,000 in 10s. shares. All shares taken up. 10s. per share called up on 7 and 1s. per share on 7,027. £354. 12s. paid, leaving 5s. in arrears. £12,239. 15s. considered as paid, being 10s. per share on 22,966 and 5s. per share on 7,027. Mortgages and charges, nil.

S. H. HEYWOOD & CO. (LTD.)—Return to March 30 gives capital as £12,000 in £1 shares. 8,007 shares taken up. £7 paid. £8,000 considered as paid. Mortgages and charges, nil.

HOWARD ASPHALT TROUGHING CO. (LTD.)—According to return to April 13 capital is £20,000 in £1 shares (1,000 deferred). 5,007 ordinary and 1,000 deferred shares taken up. £1,007 paid. £2,000 considered as paid. Mortgages and charges, nil.

MORTGAGES AND CHARGES.

ALUMINIUM CORPN. (LTD.)—Trust deed, dated May 18, 1910, to secure £50,000 debenture stock. Property charged, lands and premises in Caerhun, Dolgarrog Abbey, Dolgarrog, Llanrhychwyn, Trefriw and Maenan, rights and privileges, &c. Trustees, London General Investment Trust.

ELECTRIC BATTERIES & CARBONS (LTD.)—Debenture, dated April 25, 1910, to secure £1,000, charged on the company's undertaking and property, present and future, including uncalled capital. Holder, R. G. Orr.

FILAMENTS (LTD.)—Issue on June 1 of £80 debentures, part of a series of which particulars have already been filed.

HINDHEAD & DISTRICT ELECTRIC LIGHT CO. (LTD.)—Issue on May 13 of £1,050 debentures, part of a series of which particulars have already been filed.

RECEIVERSHIP.

SUNDERLAND DISTRICT ELECTRIC TRAMWAYS (LTD.)—A notice of the appointment of C. Eves, of Capel House, New Broad-street, E.C., as receiver and manager, by order of Court dated June 2, 1910, has been filed.

CITY NOTES.

MEMORANDA (June 16).—**Bank rate 3 per cent.** (since June 9, 1910). **Price of silver,** 24⅝d. per oz. Consols 81⅞—82⅛ for money and **for account. Consols Pay Day, July 1; Stock and Shares Continuation Days,** June 27 and July 12; **Ticket Days,** June 28 and July 13; **Pay Days,** June 29 and July 4; **Mining Shares Carry Over Day,** June 24.

PRICES OF METALS (London).—*Copper*, **cash,** 54½; **three months.** 55⅛. *Lead*, **English,** 12¾—13⅛; **foreign,** 12⅝—12¾. *Spelter*, 21⅞—22⅛. *Tin*, **English,** 146½—148½; **foreign cash,** 147½; **three months,** 148¾. *Iron*, **Cleveland, cash,** 49/-, **three months,** 49/10½.

CALCUTTA ELECTRIC SUPPLY CORPN. (LTD.)—The units delivered to consumers during the four weeks ended April 29 were 780,512, compared with 573,738 units for the corresponding four weeks of 1909.

CANADIAN GENERAL ELECTRIC CO. (LTD.)—The directors have declared a dividend of 1¾ per cent. on the common stock for the quarter to 30th inst.

CITY OF LONDON ELECTRIC LIGHTING CO. (LTD.)—The transfer books and registers of holders of the 5 per cent. first and 4½ per cent. second debenture stock of this company will be closed from 17th to 30th inst. inclusive.

COMPANIES STRUCK OFF THE REGISTER.—It is notified that the following were struck off the Register of Joint Stock Companies on June 10:—

Beeston Accumulator Synd., Birmingham Electrobus Co., British & Foreign Light Railway Synd., Electric Canal Haulage Co., Electric Mercantile Agency, International Telegraphic Appliances, Lancashire & Yorkshire Electrobus Co., Liverpool Electrobus Co., Manchester Electrobus Co., Nottingham Electrobus Co., Nottingham Gas & Electric Fittings Co., Provincial Electrobus Co., Richardson Electrical Co., Scottish Electrobus Co., Tramways Development Co.

INDIA-RUBBER, GUTTA PERCHA & TELEGRAPH WORKS CO. (LTD.)—The directors have declared an interim dividend of 5s. per share (2½ per cent.), tax free, on the ordinary shares.

NOTTING HILL ELECTRIC LIGHTING CO. (LTD.)—The directors have declared a dividend of 3 per cent., plus a bonus of 1½ per cent. (together 9s. per share), less tax, on the ordinary and preference shares.

PROVINCIAL TRAMWAYS CO. (LTD.)—The directors have declared an interim dividend of 8d. per share upon the ordinary shares on account of the financial year ending Sept. 30.

UNITED ELECTRIC TRAMWAYS OF MONTEVIDEO (LTD.)—Mr. G. A. Touche, who presided at the meeting on Wednesday, said that the period under review was the first complete year of working by electric traction, and the results had been up to expectations. The dividend which had been declared on the ordinary shares was equal to 6 per cent. for the year.

VERITY'S (LTD.)—The directors have declared a dividend at the rate of 5 per cent. on the ordinary shares for the half-year, making 5 per cent. for the year.

VICTORIA FALLS & TRANSVAAL POWER CO. (LTD.)—Mr. H. L. Cripps has joined the Board of this company.

NOTES.

Municipal Trading.

THE judgment delivered on Monday by Mr. Justice NEVILLE, in the action brought by the Attorney-General against Leicester Corporation, deals with a question of considerable importance to municipal electricity supply undertakers. The point at issue was whether a municipal corporation working under a Provisional Electric Lighting Order granted under the Electric Lighting Acts of 1882 and 1888, could undertake ordinary wiring work in addition to the supply of electrical energy. The subject has been frequently discussed by borough electrical engineers, wiring contractors and others interested in the business of electricity supply, and, although there was some doubt on the point, the opinion was generally held that a municipal corporation could not engage in work of the character referred to without special statutory powers. So general was this opinion that very many Corporations obtained powers to wire premises (in some cases only through contractors), to let motors and fittings on hire, and to do other things necessary for the development of modern electricity supply departments. On the other hand, there were some who contended that the wording of certain sections of the Electric Lighting Act of 1882 was sufficiently wide to enable municipal undertakers to do wiring work; in particular they relied on sec. 10, which authorises undertakers subject to certain conditions, for the purpose of supplying electricity ". . . . to do all such acts and things as may be necessary and incidental to such supply." The electrical engineer of the Leicester electricity undertaking (the late Mr. A. COLSON) was one of those who were of this opinion, and accordingly he established a wiring and fittings department in connection with the municipal electricity undertaking. The wiring contractors resented this, and ultimately brought an action against the Corporation, through a local contractor, for a declaration that wiring work could not be undertaken without special statutory authority; and as Leicester Corporation were not so authorised, an injunction was asked to restrain them from carrying on such work.

FROM the judgment, which is given elsewhere in this issue, our readers will see that the contractors' contention was upheld, as the Judge laid down that the business of electricity supply is distinct from electric wiring and fitting, and that the latter can only be executed by a municipal corporation when they are specially authorised to do so. On the facts of this particular case we think, and always have thought, that the principle laid down in the judgment is sound law; but whether it is for the good of the electrical industry is another matter. In some cases adequate progress is difficult unless the supply authority also carries out wiring, and in recent years the importance of being able to sell or let out on hire apparatus for electric heating and cooking has become very apparent. Indeed, in our opinion, this latter development is much more important than wiring, as the average contractor cannot afford to run a hiring or hire-purchase department. Undoubtedly, where possible, it is far better to work in harmony with the local contractors, competition being resorted to merely as a last resource; but it would be well if the contractors themselves would bear in mind the importance of real co-operation, which would be better for all concerned than war to the knife.

The "G.B." System at Lincoln.

WHILST surface contact systems generally are somewhat under a cloud, the "G.B." system at Lincoln and the Lorain system at Wolverhampton continue to give satisfaction, judging by the reports of the tramway managers in those towns. In the case of Lincoln, the tramway accounts for the year ended March 31, 1910, show a deficit of £44 after payment of all capital charges, com-

Digitized by Google

pared with £98 a year ago. It is satisfactory to notice that the traffic receipts have increased, without any curtailment of the service, from 9·2d. per car-mile last year to 9·6d. per car-mile on the present occasion. On the other hand, the working expenses have increased by £252, and now stand at 5·95d. per car-mile. Repairs and maintenance account for £187 of this increase, the cost of repairing cars having advanced from £522 to £697. It must be explained, however, that £62 of this latter sum represents spares, which have now been "written off" in the books. The cost of maintaining the "G.B." equipment amounted to £140. This, however, includes £28 for special improvements and the upkeep of feeders, so that the amount to be directly charged against the "G.B." equipment is £112, as compared with the "G.B." Company's guaranteed figure of £90 per annum. Mr. STANLEY CLEGG, the tramway manager, points out that for the four complete years of operation the cost only averages £69 per annum. On the present occasion the bulk of the expenditure has been incurred in renewal of stud heads and carbons. The life of these parts was estimated at five years, and the fact that this period is drawing to a close has accounted for an increased number of live studs—the number is not stated in the annual report of the engineer and manager—but as these studs are stated to be in no way a danger to the public it was not thought necessary to undertake a general re-carboning of the track. As the Lincoln undertaking is the smallest municipal tramway in operation, it is, of course, difficult to compare the above items of cost with those in larger undertakings, but attention may be drawn to the fact that the cost of repairs and maintenance, on the car-mile basis, is less at Wolverhampton, whilst the power consumption is greater, the average number of units per car-mile at Lincoln being 1·075, as against about 1½ units at Wolverhampton. This difference, however, may be largely accounted for by the different running conditions as regards speed and weight of the cars and the absence of gradients.

Exhaust Steam Turbines.

DURING the discussion on exhaust steam turbines at the Glasgow Convention of the Incorporated Municipal Electrical Association, several speakers were evidently doubtful as to the real value of such turbines when used for the purpose of extensions. In all probability it is in stations using an old type of plant—namely, generators that have been in use for some time and are somewhat inefficient for an increased output—that the advantages of the exhaust steam turbine are the most apparent. There are many cases in which the engineer desires to lay down fresh plant to meet an increasing load, but wishes to do so at a minimum of cost. In such cases the exhaust steam turbine will appeal strongly to those in charge, as it involves no increase in the boilers or condensing plant. Two other alternatives are generally open to the engineer. The first is to put in a high-pressure steam turbine to cope with the additional load, but in such cases more boilers and condensing plant will be required. The other alternative is that which was advocated more particularly by Mr. FERRANTI, namely, to scrap the old plant completely and to put in high-pressure steam turbines instead. This sounds a drastic course to adopt. It is, no doubt, one that would appeal to our American friends, and would probably be adopted by them without hesitation. We do not doubt that in the long run such a course might be the best to adopt, but we are inclined to think that, in municipal work at least, the engineer would find it difficult to induce his committee to accept such a recommendation; and in any case there would be much difficulty with the Local Government Board in obtaining permission for the necessary loans, for the loans on the old plant would generally not have been completely paid off, and the "scrapping" would lead to loans outstanding without corresponding assets. We do not suggest that the advantages shown for the exhaust steam turbine in the Papers read before the Incorporated Municipal Electrical Association would always be obtained, as the stations concerned were previously worked non-condensing, and the advantages of condensing, in a more or less marked degree, are obtainable with any type of steam plant. Nevertheless, the exhaust steam turbine in itself shows very decided advantages, though no general law should be laid down, and each case should be considered on its merits.

Electric Traction in Germany.—It is officially announced by the Prussian State Railways Administration that plans are being prepared for the electrification of the main lines between Magdeburg, Zerbst, Leipsic and Halle, especially the Dessau-Bitterfeld section. A large central power house is to be erected at the village of Muldenstein, near Bitterfeld, the selection of this locality being due to the large quantities of cheap coal available in the district. Alternating-current electric locomotives are to be used, employing current at 10,000 volts. Dessau and Bitterfeld will be the first sub-stations.

London County Council Tramways.—In view of the objection of the Greenwich Observatory authorities to the use of the ordinary trolley construction with rail return for the Council's tramways from Beresford-square, Woolwich, to Eltham, which pass near the Observatory, the lines are being equipped with positive and negative overhead conductors. Each car used on this route, about 2½ miles long, will, therefore, be provided with two trolley poles; and in order to allow these cars to run on other sections of the Council's track, a throw-over switch is provided for connecting the negative terminals of the motors, either to the rails or to the second wire as required. The positive and negative wires are spaced about 3 ft. 6 in. apart.

Fire Alarm.—A recent issue of the "Electrical World" states that a U.S.A. patent was recently granted to Mr. E. Lamoureux, of Montreal, for a fire alarm in which the thermal element consists of a row of compound expansion bars mounted to slide upon parallel rods. These expansion bars are of the double type, in which a stiff metal bar has riveted to its extremities two slightly longer strips of a different metal which has a larger thermal expansion coefficient. The resulting structure resembles a carriage spring in external shape, and due to the unequal expansion of its parts, varies its dimensions with the temperature. By setting a number of these bars side by side quite an appreciable movement can be obtained with a change in temperature. The expansion bar at one end of the row is fixed; that at the other will carry a hook or trigger which can be set to release a spring, thereby closing an alarm circuit when the temperature exceeds the predetermined value.

Report of the Electrical Inspector of Factories.—In his annual report, which has just been issued, Mr. G. Scott Ram mentions that only 90 out of 447 accidents in electricity works during the past year were due to electrical causes. The number of electrical accidents in factories and workshops was 257, a slight increase over the number recorded last year. A full abstract of the report will be given in our next issue.

Mono-rail in Alaska.—The "Mining World" states that the Brennan gyroscope mono-rail car is to be tried in Alaska. The scheme proposed provides for the construction of 1,000 miles of mono-rail track from the Matanuska coal fields towards Fairbanks, and the cost of construction is estimated to be about one-seventh that for a light two-rail track. If the system proves a success, it will become an important factor in making possible the opening up of mining regions only accessible with difficulty.

Wear of Steel Trolley Wire.—The "Electric Railway Journal" mentions that a recent examination of the No. 0000 grooved steel trolley wire of the New York, New Haven & Hartford Railroad, which has been in service over the main locomotive terminal track in the Stamford yard for 20 months, showed that the lower lobe of the wire was reduced in thickness by 14 per cent., or approximately one-seventh of the allowable wear. A total of 85,000 locomotive movements had been made under this wire, or four times the number of movements made under main track wires in the same period. A pantograph trolley is used. At this rate of wear a steel trolley wire over main track with the present density of traffic should last 44 years. The sample of wire examined was coated with a thin layer of grease from the pantograph collector pans and soot from the steam locomotive exhaust. When this coating was removed by wiping with waste, the surface of the wire was found to be bright and smooth, with no signs of corrosion.

Oxford University.—The new electrical laboratory presented by the Drapers' Company to Oxford University was opened on Tuesday last. Mr. Fletcher, on behalf of the Company, made the presentation. Lord Curzon, Chancellor of the University, acknowledging the gift on behalf of the University. In his speech Lord Curzon called attention to what the opening of the electrical laboratory meant to the cause of scientific research in the University. He believed that before the year 1900, when the Wykeham Chair of Physics was founded, electricity and magnetism were practically untaught in the University, notwithstanding that electricity had made most astonishing strides in recent years, and had such a future before it that its study was indispensable in an institution like their own. When they said they needed an electrical laboratory, what they meant was that Oxford needed it, not merely for examination purposes, but also to enable them to keep in touch with the most modern scientific discovery by the pursuit of independent research with the aid of the most recent appliances; and to provide similar opportunities for outside people.

City and Guilds of London Institute.—The annual report of the Council of this Institute shows that the total number of students attending diploma and special courses at the Central Technical College was 469 in the session 1908-9, compared with 438 in 1907-8, and is the highest number yet recorded. Of this total, 113 students were attending the electrical engineering course, being the same number of students as last year; whilst 227 students took the civil and mechanical engineering courses. The total number of students receiving instruction in electrical engineering, however, was 318, as against 302 in the previous year. At the close of the session in July the diploma of associate was awarded to 98 matriculated third year students, whilst 42 students of the college obtained their degree of B.Sc. (Engineering) in the University of London, 37 in honours and 5 pass. As regards the Finsbury Technical College, it is mentioned that the electrical department continues to be affected, in common with other technical colleges, by the depressed state of the electrical industries of the country; and that the rush of young men to qualify for a career in this particular branch of engineering in earlier years has probably affected the remuneration generally obtainable in the industry, and has thus diverted students to other branches of engineering, and possibly to other occupations. This probably explains the decrease to 67 in the number of day students attending the electrical engineering course at this college, as against 76 last year and 110 in 1902-3. At the close of the session 24 certificates were awarded to electrical engineering students. The evening department of the college was attended by 291 students, as against 298 in the preceding session, 91 entering the electrical department, of which number only 13 took the complete course, the remainder (78) taking single classes. The corresponding figures for the session 1907-8 were 19 and 125 respectively.

Cost of Services.—At the Convention of the Incorporated Municipal Electrical Association at Glasgow last week much interesting information was given in regard to the cost of services. Some of this will be found in last week's issue of THE ELECTRICIAN, but there are certain details which could not be transmitted telegraphically, and therefore we think it well to return to the subject briefly. The following are detailed costs in Glasgow given by Mr. W. W. Lackie, being the average of 60 services.

	£	s.	d.
Jointers' time	0	17	0
Wireman	0	6	5
Mason's time	0	6	11
Joiner's time	0	0	3
Watchman	0	0	3
Branch box	0	9	6
Fuse boxes	0	13	0
Cable	0	19	0
Compound	0	2	6
Mason's material	0	0	8½
Jointers' material	0	0	2½
Sundries	0	10	9
	£4	6	6

A short time ago the cost was about £7 per service, but this has been reduced by specialising so that each part of the work is done by a man well qualified for the purpose. Mr. F. E. Ayton, of Ipswich, gave the following figures for 2-wire services:—

	6 yds.	10 yds.
7/20 solid; two singles	£1 19 9	£2 9 5
7/18 „ „	2 0 11	2 11 0
7/20 armoured; twin	2 4 5	2 12 0
7/18 „ „	2 6 4	2 14 11

The greater cost of the armoured service is due to the cost of the service box, which will be reduced at Ipswich in due course.

Rail Corrugation.—In a pamphlet issued a year or two ago Mr. J. H. Briggs, of Leeds, endeavoured to show that the conditions which cause the effect known as chattering on tramways were to be found in the throat action of a wheel on a tramrail. The author has recently investigated the conditions for chattering, and has published his conclusions in a pamphlet entitled "Corrugation: On the Origin of Vibration in Tram Rails." He shows that chattering is possible where corrugation frequently occurs, and that chattering is impossible under certain conditions, under which corrugation does not occur. Details of experiments to corroborate this are given. All instances of chattering are the result of friction between two surfaces. This friction in the case of tramways may be caused, in the opinion of the author, by braking, accelerating, and difference in length of inner and outer rails, and that between flange and rail as a result of side thrust. As regards throat friction, when curves of large radius begin to corrugate, the throat alone of the leading outer wheel is taking the side pressure. Thus, in the case of this wheel, in passing from a level straight rail to a curve there will be a gradual change from little or no pressure at the throat through light, then heavier, throat pressure to heavy pressure on the side of the flange. The throat or flange side of the leading outer wheel can only be in contact with the rail at a position in advance of a vertical radius of the wheel. The motion of the wheel at this place is of necessity downwards. This downward motion, in conjunction with the above mentioned lateral pressure—when these are effective in the throat—only results in the friction which the author suggests breaks into chattering. We may mention that Mr. Briggs will be pleased to present copies of his pamphlet to applicants. His address is "Strathlea," Claremont Drive, Headingley, Leeds.

Electricity Supply in Boston, U.S.A.—The annual report of the Commissioner of Wires, Mr. J. E. Cole, of Boston, for the year ended January 31, 1910, has just been published and contains a large amount of data of interest in connection with recent electrical progress in that city. Mr. Cole emphasises the value of underground conduit construction as demonstrated in the blizzard of last Christmas. No fire has occurred during the year on account of wiring approved by the department. During the year, about 2,500 of the Gilbert type of enclosed arc lamps have been replaced in Boston by magnetite lamps and flame arcs for street service, and 1,200 new lamp poles suitable for the new lamps have replaced the poles formerly in service. Tungsten lamps have to some degree replaced gasoline lamps, necessitating a considerable part of the increase in new pole settings during the year, 536 in all. There are now 1,635,644 ft. of conduit installed in Boston, 10,376,795 ft. of single duct, 13,401,059 ft. of cable, 7,457 manholes, 16,886 services, 599,709 ft. of Edison three-wire tube, and 628 Edison distribution boxes. About 50 per cent. more of the above construction was installed in 1909 than in 1908. The size of cable varies from 600 pair telephone services to 2,000,000 circ. mil feeders for railway operation. The Edison Electric Illuminating Co. installed 731 underground services during the year, and put down 294,623 ft. of cable in 18,956 ft. of conduit. The Boston Elevated Railway Co. installed 24,194 ft. of conduit and 94,635 ft. of cable, and the New England Telephone & Telegraph Co. installed 111,015 ft. of cable in 13,100 ft. of conduit. In the past 15 years over 59,000,000 ft. of wire, or about 11,000 miles, have been removed from overhead service in Boston. The isolated plant capacity in Boston decreased slightly in 1909, the total kilowatt rating of the generators being 25,370 in January, 1910, compared with 25,702 kw. in 1909. The capacity of electric motors operated by isolated plants dropped from 14,986 H.P. in 1909 to 14,642 H.P. in 1910. The number of isolated plants increased from 319 to 322. The total rating of electric motors in Boston on January 31, 1910, was estimated at 331,763 H.P., including 271,449 H.P. in motors operating street and elevated cars.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Mr. E. B. Brown contributes an article on "An Accurate Electrical Method of Measuring Speeds of Rotation," the discharge from a condenser being used for this purpose.

In an article on Electric Cables, Mr. F. Fernie deals with the subject of explosions in conduits and street boxes.

Last Wednesday evening Sir John Gavey, C.B., delivered the James Forrest lecture before the Institution of Civil Engineers, taking "Recent Developments in Telegraphy and Telephony" as his subject.

The convention of the Incorporated Municipal Electrical Association at Glasgow terminated last Friday with the annual general meeting, when Mr. J. Christie (of Brighton) was elected president.

The Board of Trade have refused the application of the Lancashire Electric Power Co. for a provisional order to enable them to supply electrical energy for power in Radcliffe. The Council possess electricity supply works.

The Turkish Government are inviting tenders for a concession for constructing, equipping and working electric tramways at Salonica.

Mr. G. A. Bruce is to report upon the practicability of adopting the railless trolley system on a section of light railway at Lowestoft.

An inquiry was held at Norwich on Tuesday into the application of the Corporation for permission to borrow £17,783 for their electricity undertaking.

An inquiry was held last week into the application of Pembroke (co. Dublin) Urban Council for sanction to a loan of £8,000 for electric lighting extensions.

The estimates of the London County Council tramways for the current year are abstracted in another column.

Llandudno Council have decided, after two years' experience of incandescent gas lighting on the promenade, to revert to electric arc lamps.

Legal.—On Monday Mr. Justice Neville delivered judgment in the action brought by the Attorney-General against Leicester Corporation, and granted an injunction restraining the Corporation from carrying on wiring work, &c.

Companies' Meetings, &c.—The directors' report of J. G. White & Co. for the year ended Feb. 28th states that the Company is engaged in carrying out several important contracts in South America and elsewhere, and that the prospects of the Company are very good.

In the report of the Marconi Wireless Telegraph Co. for the period to December 31st last, particulars are given of the progress of the Company's trans-Atlantic service and of the position of several of the auxiliary companies.

INSTITUTIONS AND SOCIETIES.

INSTITUTE OF METALS.—This Institute has just published the third half-yearly volume of its "Proceedings," a book of 360 + xi. pages. The frontispiece is an excellent portrait of the President of the Institute, Sir Gerard Muntz, Bart. The major portion of the journal consists of a series of Papers read at the annual general meeting in January last. Valuable as these Papers were when they were read, their utility is now vastly increased as a result of written communications received since the Papers were read. The useful series of abstracts of Papers relating to the non-ferrous metals and the industries connected therewith, which was commenced in the second volume of the journal has been continued and amplified in the volume under notice, and there are also 48 pages devoted to abstracts on such subjects as ores and minerals, extraction of metals, electrometallurgy, properties of metals and alloys, analysis, testing and temperature measurement, statistics and bibliography. In view of the fact that the Institute is about to become an incorporated institution, the concluding section of the journal is appropriately devoted to the new memorandum and articles of association; there also appears a list of members of the Institute, which, compared with the list contained in the first volume of the journal published just a year ago, serves to show the extremely rapid strides that are being made by this, the youngest, and one of the most vigorous, of our scientific institutions.

JUNIOR INSTITUTION OF ENGINEERS.—Arrangements are being made for the summer meeting of this Institution to take place at Dublin and Belfast from July 16th to 23rd. The programme opens with a reception at Trinity College, Dublin, by the Provost and professors of engineering, and an inspection of the engineering school, &c. A visit will be paid in the afternoon to the power house of the Dublin United Tramways Co., and in the evening the Institution of Civil Engineers of Ireland will entertain the members and ladies accompanying them. On Monday morning, July 18th, Messrs. Guinness's brewery is to be visited, and in the afternoon, by invitation of the Main Drainage Improvements Committee of the Dublin Corporation, there will be a steamer excursion into Dublin Bay for inspection of the outfall works, &c. The next day will be occupied by an excursion by rail and jaunting cars for a visit to the Corporation's new reservoir under course of construction at Roundwood, Mr. J. G. O'Sullivan, the City Engineer, acting as guide. In the evening the party are to be guests of the Engineering and Scientific Association of Ireland. Wednesday morning will be left free, and in the afternoon the party proceed to Belfast, visiting on the following morning the Belfast Ropeworks at Conneswater. The Lord Mayor of Belfast, the Right Hon. Robert J. M'Mordie, M.A., will afterwards receive the members at the City Hall and entertain them to luncheon. Friday is to be devoted to an inspection of the shipbuilding and engineering works of Messrs. Harland & Wolff, by whom the visitors have been invited to luncheon, Lord Pirrie presiding. At these works will be seen in process of building the two White Star liners "Olympic" and "Titanic," each 850 ft. long and of a gross tonnage of 45,000 tons. The Institution's summer dinner takes place in the evening, at which it is hoped that the President, Engineer Vice-Admiral Oram, C.B., Engineer-in-Chief of the Fleet, will be in the chair. Saturday is left for an excursion to Portrush and the Giant's Causeway, as the concluding item of the programme.

ARRANGEMENTS FOR THE WEEK.

FRIDAY, June 24th (to-day).

PHYSICAL SOCIETY.

3 p.m. Visit to the National Physical Laboratory. A series of demonstrations will be given of work in progress in the laboratory.

TUESDAY, June 28th.

INSTITUTION OF ELECTRICAL ENGINEERS.

9 p.m. Conversazione at the Natural History Museum, South Kensington.

Digitized by Google

THE ARRANGEMENT OF EXPERIMENTAL ELECTRICAL CIRCUITS FOR LABORATORIES.*

BY W. P. STEINTHAL, M.SC.

Summary.—The author discusses the special requirements, as regards supply and distribution of electrical power, of an experimental laboratory—physical, chemical and electrical. The source of power, arrangement of circuits, and switch and plug boards are described.

The question of the equipment of laboratories for experimental work as regards the distribution of electric current first came to my notice some 10 years ago, when Prof. A. Schuster commissioned me to prepare a scheme for the new physical laboratories about to be built for the Manchester University. At that time there was no physical laboratory in this country in which any elaborate system of distribution had been adopted. It was therefore considered advisable to see what was being done on the Continent, and for that purpose the then recently completed Electrotechnical Institute in Darmstadt was selected for a visit of inspection. From the observations made at this institution, together with valuable advice and suggestions from Prof. Schuster, a scheme of electric distribution was evolved for the Manchester laboratories, and the installations that have been erected in recent years, and of which I propose to give short descriptions later, are the outcome of the experience gained at Manchester.

In arranging a distribution scheme for laboratory work we have to consider the special requirement of a laboratory in which the chief objects to be attained are: (1) To supply a source of current that will give a steady pressure; (2) to provide a centre of distribution such that various voltages can be made available on different circuits simultaneously; (3) to arrange a network of circuits that shall be as inexpensive as possible in first cost, that will lend itself easily to alterations or additions, and that will maintain a high insulation resistance.

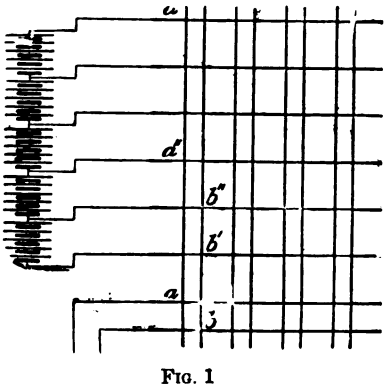

FIG. 1

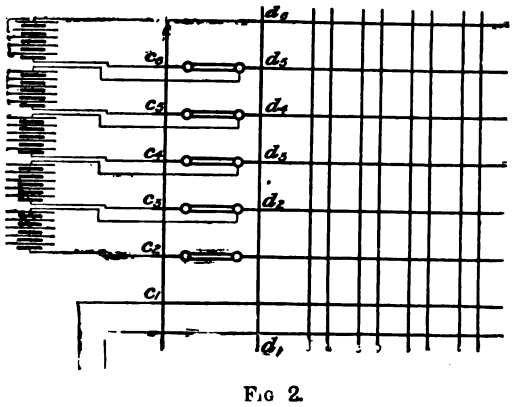

FIG 2.

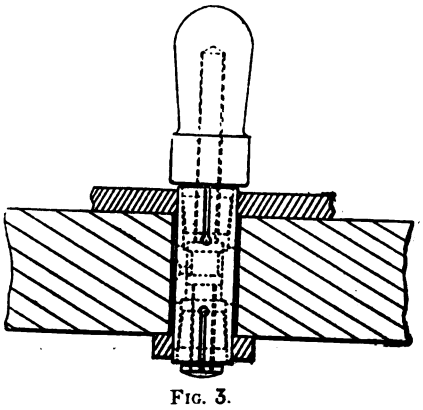

FIG. 3.

It would then appear to be most convenient to split the generator into two and instal either a dynamo at, say, 110 volts and a small booster at 50 volts (assuming that 140 is the charging voltage for the whole battery), or two similar dynamos giving 70 volts each. In the former case the two machines would be used separately or in series, and would each be driven by a motor; or, again, two converters of the type referred to above would be installed. In the latter case the two machines can be mounted on one bedplate with the motor in the centre, all three machines driving on one shaft. The generators can be used separately, in series or in parallel. The second arrangement is on the whole the more convenient of the two, because we get the additional advantage of having a set eminently suitable for running lecture table arc lamps and also providing a heavy current by paralleling the two machines. Of course, a machine giving 110 volts is almost as useful as one giving 70 volts for arc lamp work. The choice will then depend on the requirements, and, generally speaking, the first alternative is the more convenient for a physical laboratory and the second for a chemical laboratory where heavier currents are as a rule required. Next comes the provision for alternating current. Here, again, two cases arise. Firstly, where the supply is continuous current, it will be found convenient to instal a motor-generator and possibly to arrange the dynamo with slip-rings, so as to make provision for one, two or three-phase current. Secondly, where the supply is alternating, it will be merely a question of providing a suitable transformer for the requirements of the laboratory. In physical laboratories a single-phase alternating current is all that is required in the majority of cases, and the demand for current is not likely to exceed 25 amperes. But the chemical laboratory will require much heavier currents for furnace work. I believe that for certain types of furnace an alternating current is found to be most suitable and the current required may be anything up to 2,000 amperes. The heaviest currents will be used at comparatively low voltages, ranging from 26 to 50 volts. The question arises as to the best type of generator to instal for furnace work. I am inclined to follow the practice in America, and have a single-phase machine with the armature divided into four exactly similar sections, so wound that the four sections can be coupled up in series or in parallel. In the machine that I have selected each section has an output of 350 amperes at 25 volts, so that we get from the machine either 1,400 amperes at 25 volts, 700 amperes at 50 volts or 350 amperes at 100 volts. The voltages may be further varied within certain limits by varying the excitation of the fields. In cases where an alternating current is available, a transformer can be used on similar lines.

Source of Current.—For laboratory purposes a battery of accumulators is essential as furnishing the only means of providing absolutely steady currents. It may be said that any standard make of secondary battery will suffice, provided that the plate selected will allow of a high rate of discharge if required. The question then arises as to the best arrangement for charging the cells. Leaving out of account the cases where the laboratory has its own generating plant, we will consider the question of a supply from public mains. In the majority of cases we may take the voltage available to be between the limits of 200 and 250. As a general rule, the battery will consist of from 30 to 55 cells, which means that the maximum voltage required will be 140. There are then two alternatives, either to charge direct from the mains through a suitable rheostat or to instal a motor-generator. As you cannot expect to obtain a greater combined efficiency than 70 per cent. from a motor-generator of comparatively small size, it will be noted that the losses will be the same in both cases if the supply is at 200 volts, and will be in favour of the motor-generator set when the supply voltage exceeds that amount. As an alternative to an ordinary motor-generator we have now available a direct-current motor-converter. I am informed by the makers that for a machine of 12 kw. output, converting direct current from 200 to 140 volts, an efficiency of nearly 90 per cent. can be guaranteed. We have, however, more important considerations to take into account than percentage efficiency. We have to take into account that the cells will be unevenly discharged, as explained later, and that we have, therefore, to provide means for obtaining low voltages down to, say, 15 or 20 volts.

Distribution.—Here the most important requirements is to arrange a method of delivering current at any desired voltage to any of the laboratory circuits, and to ensure that the arrangement can be easily manipulated without loss of time from a convenient centre. The voltages may vary from, say, 4 up to 110, but except for certain electrolytic experiments it is probably most convenient to arrange the source of current so as to vary the voltage in multiples of 10. This being the case, we divide the battery into groups of five cells and arrange our distribution board so that these groups of cells can be connected up in series to give the necessary voltage. We then have to design the distribution board so that the groups of cells can be discharged on to any of the circuits as required. The actual type of board that I am in the habit of using for this purpose is described later, but I may here say that it is convenient to combine with the actual panels for distribution a special charging panel and also a panel to afford a simple means of connecting the groups of cells in parallel for obtaining large currents in those cases where such an arrangement is necessary, which will be more particularly the case in chemical laboratories.

Circuits.—Now as regards the circuits themselves, what type of conductor is the most suitable to employ? The choice lies between

* Abstract of an original communication to the Institution of Electrical Engineers, accepted by the council for publication in the "Journal."

Digitized by Google

insulated conductors and bare conductors, and I propose to show that the use of the latter is far more satisfactory from every point of view. The advantages chiefly lie in the cost of material and erection, and in the facilities afforded for making alterations and additions, such as tapping off extra terminal positions. Suppose we consider the necessary conductor required to carry 25 amperes. If we use an insulated conductor we should naturally work to the rules of this institution, and the size of conductor for this current would be 7/16. Now in the case of a bare conductor we can work at a much higher current density, and we have merely to consider what limits of heating in the conductor we can allow and the corresponding drop in pressure at the end of the line. Some years ago, in order to arrive at a satisfactory current density to be used for bare conductors, so as to allow of reduction of weight to a minimum and still not to risk any undue heating, a series of experiments were made, and the following formula was finally decided upon to be used for laboratory circuits: $C^2 = 15\ D^3$, where C is the current in amperes and D the diameter in millimetres. This formula gives us 22·7 amperes for a No. 10 S.W.G. wire. The drop in voltage per 100 ft. double run is therefore, in this case, nearly 2·9 volts. It may be of interest to add that a No. 10 bare copper wire will rise 18°F. from 75°F. in a room when carrying 26 amperes. Whereas to produce the same rise in the open air on a calm day in summer 42 amperes are required (*see* "Modern Electric Practice," Vol. III., p. 79).

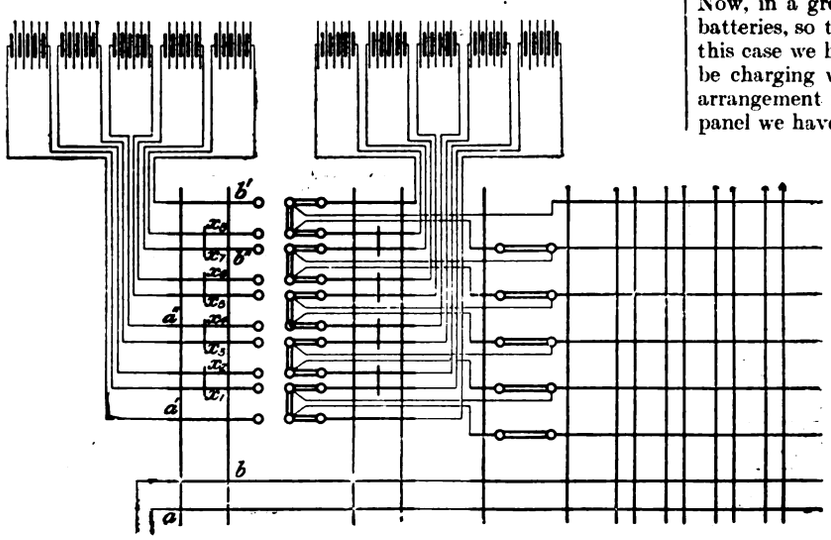

FIG. 1.

Now we see from the above that we have to compare a bare No. 10 copper wire with a 7/16 cable as regards cost, the price of the former, taking copper at 9d. per lb., being about 12s. per 110 yds., and of the latter about £5 per 110 yds. Again, in erection it is not at all objectionable to run your bare conductors overhead, spanning from point to point to obtain the shortest runs. It will, I think, be admitted that this is hardly feasible with insulated cables of 7/16 and above. So that in addition to the saving on the conductor, we shall most probably use a smaller length of bare conductor for any particular circuit. The great point in using bare conductor is to have a really first-class insulator, and if the conductors are carefully erected, you can rely on obtaining a very high insulation resistance in a dry building. As an illustration, in a laboratory that has been recently equipped, an insulation resistance of over 100 megohms has been obtained on each individual circuit, which is satisfactory, taking into account that the conductor will, on the average, be carried on at least a dozen insulators, and possibly pass through several walls.

Take, first, the simplest case, where we desire to distribute currents from a battery of, say, 30 cells, giving steps of 10 volts. We divide the battery into groups of cells, in this case six groups of five cells each. Therefore, by placing one or more groups in series we get 10, 20, 30, 40, 50 and 60 volts available. Now, if we have a panel with seven 'bus bars connected, as shown in Fig. 1, to the cells, by connecting the ends of any circuit to two of these 'bus bars we place on that circuit the voltage corresponding to the position of those bars. Instead of using switches, the most convenient arrangement is to have a series of horizontal and vertical bars drilled at each intersection and fitted with plugs to make contact between a horizontal and vertical bar. Fig. 1 shows diagrammatically such a board fed by five groups of cells and distributing to four circuits. Here we see an arrangement by which we can distribute current from the cells to any of four circuits at voltages varying from 10 to 50 in 10-volt steps.

It is, however, convenient to be able to charge the cells without having to disconnect the plugboard. For this purpose we then add two more horizontal bars, which bars are connected to the dynamo through the usual apparatus, such as automatic cut-out, ammeter, &c. It will be seen (Fig. 1) that by inserting plugs at *a*, *a'* and *b*, *b'*, we can charge the whole battery or we can pick out a single group to charge by inserting plugs at *a*, *a''* and *b*, *b''*. It will be noticed that with this arrangement we can also place current direct from the ynamdo on to any of the circuits.

The next arrangement is to have means available for connecting up the group of cells in parallel for use on a special circuit. This is effected by the device shown in Fig. 2. Here we have a pair of leads brought from each group of cells to the plugboard instead of connecting all the groups together in series at the battery. We split the horizontal bars in two pieces and interpose a single-pole switch between the two portions. It will be noticed that so long as all the switches are closed we have all the groups in series as before, and for using the four circuits we proceed in the same way as in Fig. 1. If, however, we wish to have the groups in parallel on to the special circuit, we simply open all the switches and insert plugs at points marked C_1 to C_6 and D_1 to D_6. As far as connections for charging are concerned, we use these same plug positions. Thus, to charge the whole battery, we keep all the switches closed and plug at C_1, C_2, D_1, D_6; or, supposing we desire to charge the third group from the top, we open the second and third switches and plug at C_1, C_4, D_1, D_4. Now, in a great many cases it is convenient to have two separate batteries, so that one battery is always available for discharge. In this case we have to devise an arrangement so that one battery can be charging whilst the other is discharging, and vice versa. This arrangement is effected as shown in Fig. 4. Here on the charging panel we have two identical sets of bars and plugs on each side of a vertical row of double-pole change-over switches. The centre short bars are so arranged that when all their plugs are inserted we have the corresponding cells all in series. The object of these short centre bars is to enable a single group or number of groups to be selected for individual charging. By means of the change-over switches in the centre it is possible to connect either battery to the distributing panel, and the complete arrangement enables the one battery, or any part thereof, to be charged simultaneously with the discharge of the other or any part of it.

As regards the connection of circuits to the plugboards, I have adopted two different methods. In the first, two series of 'bus bars are used, arranged at right angles to one another on either side of an insulating slab. What may be called the feeding 'bus bars are placed horizontally at the back, and the distributing 'bus bars are placed vertically on the front. A hole is drilled through both bars and the slab at each intersection, and a plug can then be inserted where desired to connect the front and back bars together. The circuit wires are connected through fuses to the ends of the vertical 'bus bars. These plugs have presented some little difficulty. It is of great importance that the contact should be electrically and mechanically sound, and that the contact between back and front bars should be made expeditiously. The first two objects can be attained with a plug having a screw connection at one end and a cone at the other, but this is expensive. It means, firstly, an expensive plug, and it necessitates tapping the holes in the back bars and providing the front bars with coned seatings. You may be able to rely upon the screwed contact, but the cone and its seating are liable to wear and finally to become unsatisfactory. The next type of plug, consisting simply of a brass sleeve split at each end, does away with the objection of having tapped holes and coned seatings, thereby saving expense. The plug itself is also reasonable in cost, and is, further, quick in manipulation, but though fairly reliable as regards contact, it is not entirely so. Both these types of plugs are in use, but the final type of plug, which I now use exclusively, is most reliable and inexpensive. This type is shown in Fig. 3. You will notice that it consists of a brass sleeve internally tapered towards each end. Through the centre runs a spindle, on which work two coned pieces of brass on a right and left-handed thread. The spindle is rigidly connected to the handle, which, when rotated, causes the two cones to move inwards, thereby pressing the ends of the sleeve, which are split to allow of expansion outwards. The rotation of the handle after the plug has been placed in position in the holes causes the plug to expand inside the holes. With this plug only parallel holes are required, and the contact obtained is electrically and mechanically perfect.

As to the second method of connecting the circuits to the boards, its advantages lie chiefly in a saving of cost in manufacture of the boards. In this method the vertical 'bus bars are entirely dispensed with, and the horizontal bars are placed on the front of the slab.

Digitized by Google

The circuits themselves are brought down to a fuse panel, Figs. 5 and 6, and flexible cords are brought from the underside of the fuses over a system of pulleys and counterweights to appropriate positions on the front of the slab, so that the plug connected to the flexible can be connected to the 'bus bars as required. The plug in this case has only to make a single contact, and is constructed on the same principle as the double-contact plug, but with a single internal cone working on the spindle. The saving in cost of this type of board is effected through the saving of the circuit 'bus bars, and the saving in drilling of the slab, the latter being a considerable item. The saving here indicated more than compensates for the cost of the pulleys and counterweight gear. The chief difficulty with this design arose in connection with the flexibles. Great difficulty was experienced in obtaining a flexible conductor to carry up to 50 amperes sufficiently flexible to run nicely over a 3 in. pulley. Several makers in this country were tried without success, but a flexible conductor was finally obtained in Germany consisting of 3,081 strands of No. 48 S.W.G. The conductor is not insulated, but merely covered with a braiding of soft cotton, as it was decided to trust to the pulleys for insulation. This decision has been justified, as on the circuits, as mentioned earlier in this Paper, an insulation resistance of over 100 megohms has been obtained, including the flexibles themselves, which will be roughly 2½ yds. long from fuse to plug. The pulleys are made of lignum vitæ with brass bushes working on a steel shaft.

I propose now to describe one or two arrangements which have been adopted for special purposes in connection with distribution of current. In the first place, it may be of interest to describe a device designed to prevent plugs being inserted into wrong holes on distributing panels. Supposing we take the case of a distributing panel for eight circuits, that means we have 16 'bus bars, and in this particular case we arrange that the vertical circuit bars shall be at the back and the horizontal feeding 'bus bars on the front. We desire to ensure that one plug only can be inserted in any horizontal bar at the same time. For this purpose we have an ebonite guard bar fitted between the 'bus bar and the slab, and free to slide backwards and forwards parallel to its length. There are the same number of holes in the ebonite bar as there are in the horizontal brass bar, but the holes are so spaced that when one hole in the ebonite bar corresponds with a hole in the brass bar, and so allows a plug to go through both, all the other holes are out of adjustment. The spacing of the holes is found as follows: Suppose we space the holes in the brass bar at 1⅞ in. centres. We have 16 holes, so that the total distance between the two extreme holes is 15 in. by 1⅞ in.; if we take sixteen-fifteenths of this length, and divide the result by 15, we get as the result 2 in., which will be the spacing for the holes in the ebonite bar. And it will be found that this spacing satisfies the condition required.

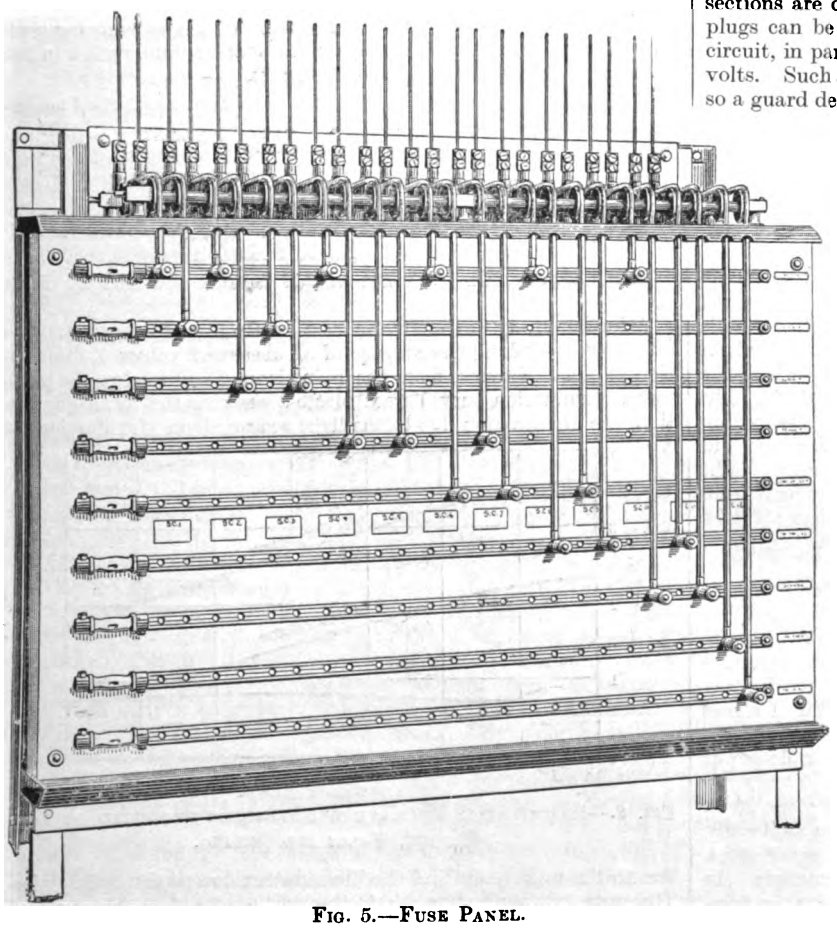

Fig. 5.—Fuse Panel.

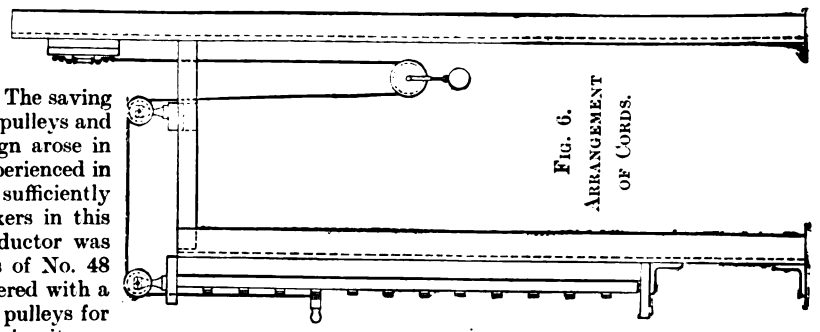

Fig. 6. Arrangement of Cords.

The second special application of plugs that I propose to describe is an arrangement for high-tension work to prevent accidental contact with 'bus bars carrying a high-tension current. We have a plugboard arranged to place four sections of a transformer secondary in series or in parallel. Assume the transformer primary to be fed by a single-phase alternating current at 100 volts, and that the secondary is split into four equal sections, each giving 250 volts. These four sections are connected to a board, and by means of double-contact plugs can be arranged in series to give 1,000 volts to the external circuit, in parallel to give 250 volts, or in multiple series to give 500 volts. Such an arrangement might be a source of danger to students, so a guard device is necessary to prevent accidental contact with the 'bus bars. In the first place, a sheet of plate glass, perforated with the necessary holes to allow of the insertion of plugs in the proper positions to obtain the required voltage, is fitted on the front of the board. The double-contact plugs are fitted with elongated handles in which are cut circular grooves. An ebonite bar, pivoted at both ends, and therefore free to move about an axis parallel to its length, is provided at proper intervals with slots, which engage with the grooves in the plug handles. One end of the ebonite bar is connected by means of a link with the handle of a double-pole switch, which is placed into the primary circuit of the transformer, and is so set that when the switch is closed all the plugs are locked by the ebonite bar, and can only be moved after opening the switch. Thus, when the 'bus bars are alive, the plugs can neither be inserted nor withdrawn.

Generally speaking, it is obvious that a combination of plugs and switches can be arranged to meet almost any desired purpose, and I should like to point out the very great convenience arising from these arrangements in laboratory work. There is a great saving of time and trouble in being able to set your connections in a simple way by means of these plugboards, instead of having to work with loose wires and cables.

Terminals for connecting Apparatus to the Circuits.—In designing the general scheme for a laboratory we have to consider the requirements of three classes of students: Elementary, advanced and research. The requirements for elementary students are for most purposes met by small portable batteries. But it is convenient to have circuits available for use from the central distribution system as well. The current required by each student will be small and the voltage low. The most convenient arrangement is probably to feed the elementary laboratory with a couple of 50-ampere circuits, and arrange a series of tappings off the circuits, whose number will depend on the number of students working together in one class. In the case of more advanced students it is best to set apart a number of circuits for their exclusive use, feed these on to a separate plugboard, and wire the necessary number of terminal positions off this plugboard, arranging so that not more than two students are working off the same circuit simultaneously. For research work it is advisable that each terminal position should be an entirely independent circuit, so as to ensure absolutely steady currents and avoid any risk of the circuit being interfered with by another experiment.

The capacity of the various circuits must depend upon circumstances in each particular case, but, generally speaking, physical

Digitized by Google

laboratory circuits are best arranged for 20 and 50 amperes, and those in chemical laboratories for 50 and 100 amperes.

Special Conductors.—In certain rooms of a physical laboratory it is necessary to eliminate all possible magnetic effects from the circuits. This can be attained either by crossing the conductors at short intervals or by changing from bare conductors to insulated concentric cables. For furnace and other heavy current circuits copper strip may be conveniently used, fitted on iron brackets with the usual pattern of 'bus bar insulator. A current-density of 2,000 amperes per square inch may be used, as a drop in pressure is not material, and these circuits are usually very short. For the lecture tables it is best to bring the bare copper as close to the table as may be convenient, and then finally connect up to the terminals on the tables with insulated conductor.

The author finally gives brief particulars and diagrams of connections of three recent laboratory equipments, in which the foregoing principles have been embodied.

ILLUMINATION TESTS.*

BY CLAYTON H. SHARP AND PRESTON S. MILLAR.

Summary.—Particulars are here given of the results of tests on a particular installation to ascertain the light flux derived from the light source, ceiling and walls respectively. Tests were also made to ascertain the reflecting efficiency of the ceiling and walls, and to determine the intrinsic brilliancy.

Most illumination tests have been made with some specific purpose in view and hence have not included some of the elements without which a study of an illumination installation cannot be said to be complete. It is the purpose in this Paper to present the results of certain illumination measurements which have been made chiefly with three objects in view:—first, to illustrate tests which can be made and methods which may be employed in the study of the illumination of an interior; second, to illustrate methods of discussion of results; and third, to illustrate the degree of accuracy which it is practicable to attain in work carried out with ordinary field equipment.

Test Conditions.

The tests were conducted in a room 12 ft. 7 in. long, 12 ft. 2 in. wide and 9 ft. 10 in. high. The ceiling was covered with white cloth. The walls were grayish white, and the windows were covered with manila paper. There were provided for the ceiling and walls black cloth coverings, which reflected practically no light and which could be removed readily. A screen was constructed by which the test-plate of the photometer could be shielded from all direct light from the light source, while a minimum of light from the ceiling and walls was obscured. A second screen was of such shape and dimensions as to shield the plate from all direct light from the light source and from the ceiling, while obscuring a minimum of light from the walls. A third box-like screen was so designed that all light reflected from the walls directly could be screened from the test-plate, while a minimum of ceiling light was obstructed.

The light source consisted of a single 250 watt bowl-frosted, metallised filament lamp, supplied at the watts necessary to produce its rated candle-power and equipped with a satin finish prismatic bowl reflector, mounted in a form A holder. This unit was mounted upon a drop cord from a centre outlet on the ceiling, the bottom edge of the reflector being 9 ft. 4 in. above the floor. Fig. 1 shows the curve of the distribution of light about the lamp and reflector used in these tests. The values given are apparent candle-power as observed at a distance of 10 ft. from the light source.

Studies were made of the illumination on a horizontal plane 36 in. above the floor (the "table plane"), and on the ceiling and walls. The horizontal plane was divided into 25 rectangles of equal areas. A test station was located in the centre of each such rectangle. In some of the tests upon the ceiling, corresponding test-station measurements were followed. In other tests, stations were located in the centres of large rectangles, both upon the ceiling and upon the walls. At each test-station, three to five settings were made by one observer.

Illumination on Table Plane.—It was desired to determine by direct measurement, not only the total flux on the horizontal plane with the room in its normal condition, but also the proportion of such flux which was contributed by the light source directly, by the ceiling and by the walls, respectively. Thus, with the walls and ceiling covered with black cloth, the illumination on the table plane was that due to the lamp alone: with the walls black and the ceiling white, the illumination was due to the lamp directly and to the light of the lamp reflected from the ceiling: with the direct rays of the lamp screened from the test-plate, the illumination measured was that due to the light of the lamp reflected from the ceiling, plus the light of the lamp reflected from the walls, plus the light of the walls reflected from the ceiling, plus the light of the ceiling reflected from the walls. In all tests, the light reflected from the brown linoleum-covered floor, from objects on the floor and from the wainscoting, below the 36 in. plane, has been ignored.

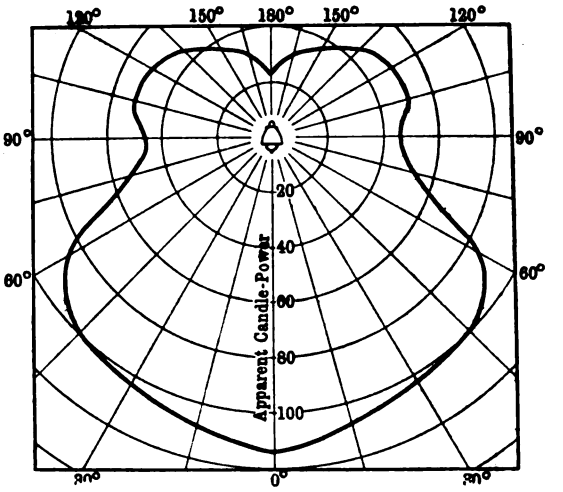

Fig. 1.—Light Distribution in Vertical Plane from 250 watt Gem Lamp with E13 Reflector.

The results may be summarised as follows, the value being given in lumens (obtained by multiplying the average illumination in foot candles by the area of the plane, 153 sq. ft.):—

Component flux from	Total lumens.
Light source direct	191
Ceiling alone	42
Walls, via ceiling	26
Walls alone*	86
Ceiling, via walls	35
Total	380

This checks against a value of 373 lumens obtained by direct test.

A further study of the illumination on the test-plane can be made as follows:—Taking the average of all measured values of illumination at equal distances from the point immediately below the lamp, mean illumination curves were plotted, showing the total illumination, the illumination due to the light source alone, the illumination due to the walls alone and the illumination due to the ceiling alone. The curve of illumination due to the light source alone is not strictly comparable with that derived from the distribution curve, since the latter was measured at a distance of 10 ft. from the light source, whereas the distances involved in the measurements in the room, varied from 6·67 ft. to 9·67 ft. Nevertheless the comparison is an interesting one. These curves are shown in Fig. 2. In comparing point by point the measured total illumination intensity with the sum of the components, the differences were found to average less than 2 per cent., the maximum individual variation being 5·4 per cent.

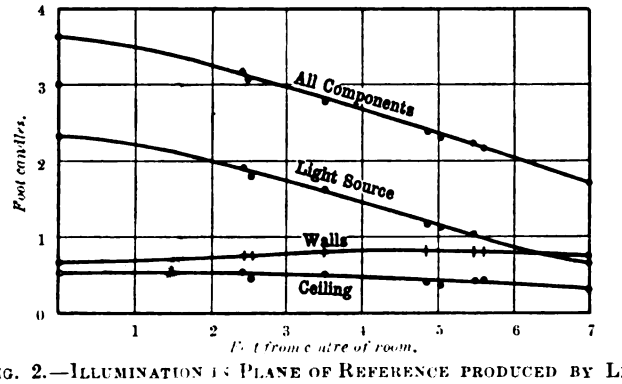

Fig. 2.—Illumination in Plane of Reference produced by Light Source, Walls and Ceiling.

Illumination of Ceiling and Walls.—In studying the illumination of ceiling and walls, photometric procedure was followed, which can be employed satisfactorily only with some form of illumination photometer, of which the illuminated surface or test-plate may, when

* Abstract of a Paper read before the New York Section of the American Illuminating Engineering Society.

* This value includes light reflected from wall to wall prior to being reflected from a wall to the plane of reference.

Digitized by Google

required, be located at a considerable distance from the photometer itself. The accuracy of the results obtained will depend, of course, in great measure upon the precision capabilities of the photometer used, the extent to which the photometer complies with the theoretical requirements, and upon the skill and experience of the observer. In the tests here described a detached test-plate was located on the ceiling or wall in the position and at the angle desired. The photometer was removed from the test-plate a sufficient distance to minimise obstructions of light due either to the instrument or to the body of the observer. The test-plate in this instance consisted of a circular sheet of de-polished milk glass, 100 sq. in. in area with an opaque backing. This detached test-plate was viewed normally through the photometer in all cases. While not a perfect diffusing surface, it followed the cosine law with substantial accuracy through an angle of 60 deg. from the normal, and therefore served all practical purposes in these tests. It is not to be expected that the results with the detached test-plate will be as accurate as with the plane of reference previously considered, in which the test-plate was attached to the photometer.

Analysis of Ceiling Illumination (data refer to flux incident upon entire ceiling area).

	Lumens.
Direct from light source	183
Ceiling light reflected by walls back to ceiling	20
Wall light reflected to ceiling	77
Total flux on ceiling	280

Analysis of Wall Illumination (data refer to flux incident upon entire wall area.)

	Lumens.
Direct from light source	382
Ceiling—first reflection	116
Walls—first reflection	104
Ceiling via walls+walls via ceiling	70
Total flux on walls	672

Among the values determined for the illumination on the table plane, ceiling and walls, there is for each the flux of light incident from the light source direct, all indirectly reflected light being eliminated. The sum of the values of such components upon each plane is comparable with the total flux of light produced by the light source, as computed from the curve of light distribution. Such a comparison is as follows :—

	Lumens.
Direct light incident upon ceiling	183
" " " " walls	382
" " " " reference plane	191
Total	756
Total flux computed from distribution curve (Fig. 1)	779

This check of the illumination tests shows accord within 3 per cent. It is an excellent demonstration of the validity of the methods employed, and of the substantial accuracy of the results.

Ceiling as a Reflecting Surface.—From the data in the tables it is possible to compute the reflecting efficiency of the ceiling under the conditions which prevailed. From the following figures it will be noted that 63 per cent. of all light falling upon the ceiling from the walls is reflected by the ceiling, while the corresponding value for the light incident upon the ceiling from the light source alone is 86 per cent. This difference is probably due to the fact that the ceiling receives the bulk of the light from the light source at angles of very high incidence, under which condition it would naturally display a most favourable reflection coefficient. Moreover, the cloth of which the ceiling was composed allowed less light to pass through its interstices at high angles ; hence reflected a larger percentage.

A corresponding study of the walls as reflecting surfaces is also given.

The low value for the percentage of light reflected by the walls on the test-plane and ceiling seems reasonable, if we remember that a very large proportion of the reflected flux travels from wall to wall and is finally absorbed. The components of this flux falling upon the test-plane and upon the ceiling may reasonably be expected to be rather small ; in fact, a simple comparison of the areas involved would indicate that the test-plane and ceiling would receive a smaller percentage of the light reflected from the walls than do the walls themselves.

Specific Intensity or Intrinsic Brilliancy.—In view of the great importance of this element in illumination installations, it was decided to make such determinations upon the walls and ceiling. Time did not permit of an exhaustive study, but the determinations were made for the ceiling when it received the total direct and indirect light flux, and again when the walls were covered with black cloth ; also for the walls when they received the total direct and indirect light flux.

Ceiling as a Reflecting Surface.

The detached test-plate previously referred to was calibrated as a standard of specific intensity by producing upon it illumination of high intensity, determining the intensity, and determining the illumination which the detached test-plate produced under those conditions at a stated distance. For example, in the standardisation test an illumination of 58·8 ft.-candles was produced upon the test-plate, and it was found that under this condition the test-plate produced a normal illumination of 0·393 ft.-candle at a distance of 5 ft. along a line perpendicular to its surface. This yielded a specific intensity of 0·0982 c.p. per square inch for the test-plate as illuminated, which corresponds to a specific intensity of 0·002 c.p. per square inch per foot-candle of illumination. After the illumina- intensity had been measured by means of the detached test-plate, the test-plate was removed, while the photometer remained in position, and repeated observations yielded the specific intensity of the ceiling or walls as compared with that of the test-plate. Some of the determinations made by this method are as follows :—

Specific Intensity or Intrinsic Brilliancy of Ceiling and Walls.

		Specific intensity (in c.p. per sq. in.) Mean for surface.	Min. measured.	Max. measured.
Conditions.	Surface.			
Nothing obscured...	Ceiling	0·0032	0·0014	0·0037
Walls black	Ceiling	0·0016	0·0005	0·0061
Nothing obscured...	Walls	0·0031	0·0023	0·0047

The value given for the mean specific intensity of the ceiling, 0·0032 candle per square inch, may be roughly checked by the use of the following equation : $F = \pi i$, where F is the average flux per square in. of the ceiling ; or in other words, the total flux divided by the area of the ceiling in square in., and i is the specific intensity required. The value so derived for the mean specific intensity will be larger than the value obtained by measurement, because it is based on the assumption that the surface of the ceiling is a perfectly diffusing surface, which it was not. The mean value for the first test of the ceiling, computed according to this equation, is 0·0949 candles per square in.

BRAKE SHOE STANDARDISATION.*

BY J. A. PANTON.

Summary.—Attention is first called to the large amount of waste in connection with brake heads and blocks. The author then discusses the properties of the various types of brake blocks, and finally suggests a standard design which, he claims, will show a saving of over 100 per cent. in material.

The question of brake shoes and their wear, consistent with economy, safety and efficiency, is of greater importance than appears at first sight, and has up to the present time failed to receive due consideration. When you consider that the outlay on brake blocks is 10 per cent. of the car maintenance, it will be recognised as a very important factor in economy, and it is here suggested that as much attention be given to the scrap heap as to the brake block itself. At the present time some 40 to 60 per cent. of the material received is returned to the scrap heap partly worn; not worn out, but worn to such an extent that their consignment to the scrap heap is a wise precaution against accident. With heavy equipment and high-speed brake application, it is found that a soft cast-iron shoe in cooling after a hard and heavy application takes a sharper curve on the face than on the wheel, and this shoe, when re-applied at the next application, unless thick, will crack and break off.

A few years ago blocks were frequently made in one solid piece, so that the brake block itself could be attached direct to the truck lever. This method increased the weight of that portion of the block that goes into scrap, and it also required more time and labour in changing. The chief reason for the brake block being made in this manner was probably because of the limited space between the wheels. The lengthening of the wheel base a few inches has removed this difficulty, and the brake shoe has been generally adopted.

The original weight of brake blocks is found to vary between 20 lb. and 36 lb. Where space is not limited, it would seemingly be good practice to use the heavier blocks, which would remove the necessity for frequent changing. The figures given for discarded blocks of the above weights vary from 15 lb. to 24 lb., and correspondingly lower figures when steel backs are used.

In general it might be said that the weight at which blocks are discarded could with advantage be given considerably more attention than is customary. The scrap heap offers convincing evidence of this. Blocks are frequently found worn thin at one end, while the other end has barely been in contact with the wheel, and it is safe to say that not more than two-thirds of the available material is usually worn away. The fault usually lies in the length and adjustment of the hangers and design of brake shoe used, which does not permit of these being worn out, even if they could. The reason of this waste material is not far to seek, as the present plain cast-iron brake shoe has many disadvantages, apart from lack of inherent strength against breakage.

Plain Cast Iron.—This material is approved by many on the grounds that it is cheaper to wear out the brake shoes than the wheels, also to the fact that the frictional properties are comparatively uniform and high under all conditions of service. It will probably surprise many to know that wheels wear quicker without brake shoes than with them. Brake shoes assist in preserving the wheel camber. Although effective and efficient, they unfortunately show two very distinct objections and disadvantages for general use—namely, rapid wearing qualities and lack of strength against breakage.

The action of cast-iron shoes upon steel and chilled-iron wheels has been explained on the theory that the surface of a cast-iron shoe is characterised by sharp projections of a crystalline nature, and that these crystals under wear become readily detached and break along the cleavage faces, continually furnishing angular crystalline particles to grind between the shoe and wheel. The face of the chilled wheel is a series of minute elevations and depressions, and when pressed together the two surfaces interlock and mesh with the particles ground off from the shoes, so that there is a continuous grinding and rolling action, and consequent high friction and heavy wear on blocks. The steel tyre is not so hard as the chilled wheel, and possesses an element of ductility, so that projections on its face tend to flow or bend away from the brake shoe, to become compact and polished over, affording less resistance, and permitting a sliding rather than a grinding action between the two surfaces, and consequent wear of both wheel and block, producing excessive heat, which in turn causes a corresponding fall in retardation. With the harder qualities of cast iron it is possible to have considerable difference in wear with equal retarding effects.

Part-chilled Blocks.—With partially-chilled blocks there is less wear and a more even coefficient of friction throughout the process of retardation; any slight heating is dissipated in the chill, which to some minor extent assists retardation without rapid wear, and protects the intermediate soft iron which produces the necessary friction between the surface chills, thereby occupying a very useful intermediate position in braking efficiency and durability. The one great drawback at present about partly face-chilled blocks is that the chill does not penetrate more than ¾ in. into the body of the block; hence, when the block is only one-third worn, we arrive at very soft iron with rapid wear and increased coefficient of friction, resulting in chattering and erratic stops as the speed is being reduced, owing to various brake-shoe coefficients. Hence the necessity of chilling from the back as well as from the front in staggered positions, so that the retarding properties may correspond equally throughout the wear; therefore brake shoes should be purchased from manufacturers who specialise in this class of work.

Composite Brake Shoes.—The composite shoes of various grades of hard and soft iron and steel inserts give better results on steel tyres, but tend to tear the tyre by reason of hard spots forming on the inserts that fuse and roll between the shoe and wheel, preventing bearing on the entire wearing surface of the wheel.

All-Face Chill Blocks.—Some five years ago, in this country, a part-chilled block or chill of any description was utterly condemned; to-day we find a great many in use even to the extent of an all-face chill block. The author cannot go this far unless under great caution, as the all-face chill block is only suitable where very soft wheel tyres are in use. The present-day tramway and railway managers are in favour of very hard and high quality steel-tyred or chilled-iron wheels, and by the use of hard-face chill brake blocks on such wheels no reasonable friction is obtained, as the two surfaces immediately get highly polished, forming what is known as an all-chill glaze, which in turn, under the best dry conditions, involves a very low coefficient of friction and unnecessary heavy wheel pressure, resulting in undue heating, with its attendant drawbacks (in wet weather). It is with a block of this class (in wet weather), when a car is about to descend an incline, that the worst possible conditions may be obtained. The block is saturated with water, therefore the temperature of the wheels and blocks will be low. The coefficient will not be sufficient in the first few seconds to generate the heat required to evaporate the film of water between the blocks and wheels, with the result that racing may occur.

White Iron Blocks.—The above results with all-face chill blocks apply equally to hard white-iron blocks, with a greater tendency of this type of block when heated being liable to crack and break off, the nature of the material being very short in the grain and without ductility. Hence their early removal from service when only part of the material has been worn off. In the same way the glaze is here recognised by the squealing effect obtained when the car is coming to rest. Cracks in all-chilled or white-iron brake shoes result in total fracture unless precaution is taken to hold the parts together regardless of cracks. Brake-shoe manufacturers have resorted to the steel plate reinforcement at the back of the shoe, which is so designed as to anchor the cast-iron body firmly to the back. The brake shoe to meet to-day's requirements should have a steel back, and is a success, regardless of the facts that the extra durability for wear in the brake shoe required by many officials necessitates the use of a grade of iron which does crack under conditions of modern service. Hard cast iron is a metal which appears to have a lower rate of heat conductivity than soft cast iron.

End-chilled Blocks.—Another type of casting has the block ends chilled, and presents decided wearing qualities as well as decided tearing qualities, the outer edges presenting sharp cutting faces to the wheel tread, so that in reality the wheel tyre suffers more than the brake shoe.

The various types of shoes described above group themselves into three distinct classes with respect to braking results. The first class covers the soft-iron shoe, which is the most efficient though least desirable, on account of rapid wear. The second class embraces the part chill and composite shoes with hard and soft inserts, which occupy a useful and intermediate position in braking efficiency and durability. The third class includes heavily chilled and white-iron shoes, which are the least effective in braking, though most durable.

Suggested Improvements.—Having described the various results obtained from the blocks now in use, the author is still under the impression that a better brake block can be so manufactured to suit individual and local circumstances that it can be depended upon to control cars either in case of emergency or in making service stops, and to have pronounced retardation by reason of friction between block and wheel, so that the maximum braking effect can be attained. Secondly, the selection of brake shoes of the size, shape and metal best adapted for their service in stopping the car promptly, and with the least possible pressure, and at the same time preserving and conserving as much as possible the size of the wheel and its original contour of flange and tread.

* Abstract of a Paper read before the Tramways and Light Railways Association at the Dublin Congress. A brief account of the discussion in connection with this Paper was given in our last issue.

UNIVERSITY OF CALIFORNIA

Hitherto the chief improvements in tramway brakes have been effected by the introduction of various forms of track brakes, but it seems to me that the track brake can at its best only be regarded as supplementary to the wheel brake when properly understood. The Brake committees have reported very fully on track brakes without giving much attention to the actual wheel brake shoe with varying conditions and materials in contact, and the desired foot-pounds of work done by that material for a given amount of wear has still to be ascertained. Hence the wheel brake has been made responsible in connection with many runaway cars. The importance of determining the effect of the shoe upon the wheel becomes apparent when one considers the possibility of a shoe showing a high resistance to wear, which may, in fact, be protected at the expense of wear upon the wheels. It is suggested that a specification should be framed on these lines, covering frictional qualities of brake shoes, provided that shoes when tested shall give results as follows: Upon a chilled wheel in effecting stops from a speed of 35 miles per hour a mean coefficient of friction of not less than 22 per cent., when the brake-shoe pressure is 2,800 lb., and a steel-tyred wheel in effecting a stop from a speed of 60 miles per hour a mean coefficient of friction of not less than 18 per cent., when the brake-shoe pressure is 2,800 lb., or an average of 20 per cent. for all purposes; that the rise in the value of the coefficient of friction at the end of a stop shall be within such limits; that the value of the coefficient of friction for a point 15 ft. from the end of the stop shall not exceed the mean coefficient of friction by more than 7 per cent. The general conclusion is that commercial brake shoes at present as a rule meet this standard as to mean coefficient of friction during a stop, but they fail in most cases as to the increase of coefficient of friction at a point 15 ft. from the end of the stop. The author is of the opinion that while a high coefficient of friction is in the abstract a desirable characteristic to be possessed by a brake shoe, operating conditions make uniformity of action

Suggested Standard Brake Head and Shoe.

desirable for the purpose of securing uniformity both in time and intensity of its action, in order that the surging of trains and trailing cars may be prevented. Many interests would be served if manufacturers, in submitting shoes for test, would give a statement covering wearing qualities as well as a statement covering coefficient of friction. It is also possible that if a satisfactory test could be formulated, specifications covering wearing qualities might be framed. In order to arrive at this, the author submits in the Paper a test sheet which he suggests should be sent out, and the information secured carefully collated by an engineering committee, together with other material upon this subject, to form the basis of a report on brake-shoe standardisation.

Brake-shoe Heads.—Improvements have been made in the past by separating the head from the shoe, accomplishing a saving in first cost and scrap weight, but the practice still remains expensive on account of lack of interchangeability. It would, therefore, seem important that we consider this question with a view to having all brake heads made strictly in accordance with the present contours or dimensions, to ensure more satisfactory service and avoid the difficulties which have been experienced in fitting the brake shoe. The shape of the brake head may be allowed to vary in accordance with the truck design, provided always that they fit the standard shoe. Within the last two years steel-back brake shoes have been introduced; heavy and high-speed equipments demand a shoe of this type, which practically doubles the life of the shoe, with less strain on the brake head. The best argument in favour of steel-back shoes is that they can be worn down very thin without danger of breaking and causing derailment of the car. A similar remark also applies to the present cast-iron key lug, which breaks in service very frequently, thereby accounting for brake failures and accidents. Improvements have been attempted in this direction by casting in steel bands reinforced and supported by the cast metal of the shoe, a practice which developed blow holes on account of the fusing of the metals, and separation of the lug from the casting while in service. It would, therefore, seem desirable in designing a standard that particular attention should be given to avoid these defects; that the iron lug should be sufficiently strong without other supports and well protected during the process of casting.

Standardisation.—Attempts recently made to obtain definite figures regarding the wear of brake shoes disclose the fact that close records of this important feature are not kept in a great many car shops. It may be argued that there is no need for such figures. On the other hand, it is reasonable to presume that the more definite the information that can be secured in car-shed practice about such a considerable item of expense as brake shoes the greater is the probability of reducing expenses. The number of stops and the weight of cars differ so widely on different systems that widely varying brake-shoe mileages are obtained. Difference in operating conditions is also largely responsible for the wide difference in brake-shoe mileage obtained; therefore our present method of cost per 1,000 car-miles is obviously wrong. Braking pressures must vary directly with the weight of the car. Brake-shoe wear will vary directly as the braking pressure and work accomplished, and, therefore, it is not considered as important for purposes of comparison to know the cost per 1,000 car-miles or ton-miles as it is to know the "percentage of metal worn." The standard brake shoe should be one-third the diameter of the wheel tyre (within reasonable limits) or applicable to any wheel from 30 in. to 33 in.

The pressure applied to the brake shoe on tramways at present varies according to the weight of the car. But the total brake pressure applied should not exceed 75 per cent. of the total weight of an empty car. With the latest type of "Peacock" and "Ackley" geared brake spindle a common standard of brake pressure applied by the motorman could be arrived at for all weights of tramway cars between 8 and 15 tons.

Whatever may be the pressure arrived at, the results clearly distinguish between the slow-wearing and the rapid-wearing shoe. All shoes wear more rapidly on a steel-tyred wheel than on a cast-iron wheel. In general terms it may be said that for the absorption of a given amount of work the wear on brake shoes upon the steel-tyred wheel is twice as rapid as upon a cast-iron wheel. A standard shoe should, therefore, develop for each pound of metal worn away 350,000,000 ft.-lb. of work in contact with a cast-iron wheel and 200,000,000 ft.-lb. of work in contact with a steel-tyred wheel. A standard specification framed along these lines would form a basis for comparative tests on brake-shoe wear, regardless of any and all conditions of running, and would in all probability reject 50 per cent. of inferior wearing material now offered for service. This would involve no extra expense to the manufacturers, as some manufacturers have for many years given practical attention to these requirements, and can fully demonstrate that it is entirely practicable to do so.

Standardisation does not mean standard material, but does mean standard design, for all classes of material to suit the different conditions and attain the standard coefficient of friction and wear herein described. Now that through running of cars is an established fact, standard design is essential in case of failure necessitating interchange of wearing parts.

In the standard brake head and brake shoe submitted (*see* illustration herewith) it will be noticed that the plan contemplates keying the contacts at the centre lug of the brake head, while the ends of the brake head fit close to the full length and width of the brake shoe back, that function being a great support to the shoe. The raised recess at each side of the iron lug, in conjunction with the end abutments, is merely to keep the shoe in vertical alignment, and should fit the holder and lug so snugly as to prevent any upward or downward movement of the shoe, the centre lug transmitting the load directly to the beam by virtue of the usual wedge-shaped key. In practice a great deal of play is often found at this point, which is very objectionable, as it allows the shoe to chatter up and down with the rotation of the wheels. Also many brake heads are found which bear at the ends and lack contact in the centre, causing the shoe to break at the centre when worn. Many brake heads will not allow the brake-shoe key to be properly driven into place.

On a large proportion of electrical equipments we see that the brake head is carried over the flange portion of the brake shoe. This means that whenever a brake shoe is worn through the flange (and that is generally what happens in the effort to obtain longer life out of the shoe), the brake head is worn. If another shoe is applied to that head it will not fit, and consequently does not do its proportion of braking work; the brake head is therefore scrapped after a short life. The proposed standard brake head shown has been so designed that however much the block may be worn the brake head cannot be injured.

Digitized by Google

On examination of the proposed standard shoe it will be noticed that quite a little unnecessary metal has been removed from the flange and back of shoe. The author believes that better results in braking would be secured if all the braking were done on the tread of the wheel instead of the flange, for the following reasons: (1) The effect of using a flanged brake shoe is that the sand and grease, which is carried up by the wheel, collects at the root of the flange, causing unequal wear and hard braking. (2) The brake shoe crowds into the throat of the wheel tread (causing sharp flanges) in the endeavour to get on to the larger diameter of the flange, with the tendency to climb and tip the block up at one end, causing chattering. (3) When the wheel flanges are chipped, the flange catches the shoe suddenly, causing the brakes to buck. By omitting the flange portion of the shoe these difficulties would be obviated, and there would be fewer flats on wheels; or that sufficient flange only be left to steady the brake shoe, and made with a deeper opening, so that it will guide the shoe without braking on the flange. By removing the waste material from the back of the shoe and the intervening air spaces, we would get ½ in. more wearing material on the body of the shoe in slightly less space than by adopting the old practice. The proposed standard shoe may, with all safety, be worn down to the steel back, while the old style has to be removed when half worn to prevent the wheel flange from wearing out the brake head.

——	Wt. of head.	Wt. of shoe.	Cost of shoe.	Thickness of shoe.	Metal worn away.	Cost of metal worn.	Metal scrapped.
Old practice	14¼ lb.	22 lb.	1/10½	1⅝ in.	8 lb.	8d.	14 lb.
Standard practice...	19¼ lb.	19¼ lb.	1/8	2¼ in.	17 lb.	1/5¼	2¼ lb.

The above figures show comparative details and indicate a saving of over 100 per cent. in material. A brake shoe of this type has a particularly fine opportunity to effect a large saving by its application, other than those which will bring immediate benefits of a financial sort. We would have less weight purchased, less weight scrapped, less material handled and a better service, with less cost all round.

AN ACCURATE ELECTRICAL METHOD OF MEASURING SPEEDS OF ROTATION.

BY E. B. BROWN, B.SC.

The measurement of speeds of rotation by means of a condenser was suggested by Maxwell's historical determination of the absolute capacity of a condenser, and has been carried out in different ways by various experimenters. The following modification of the method in which a special type of differential galvanometer is used will, the author belives, prove very convenient, and is of sufficient importance to merit publication. It is capable of a high order of accuracy and its convenience is such that in many cases it will meet a long felt want in the electrical testing room.

By means of a rotating commutator a condenser is alternately charged by a battery, and discharged through one coil of a differential galvanometer. The steady deflection which would exist due to the rapid succession of discharges, is opposed and prevented by a steady current from the same battery passing through the second coil of the differential galvanometer. This steady current is adjusted by variable resistance in series until the galvanometer is restored to its zero position.

The ratio of the steady current to the mean value of the pulsating current will be a constant for the instrument, but the steady current is equal to the P.D. of the battery terminals divided by the total resistance exterior to the battery, while the mean value of the pulsating current is equal to the product of the P.D. of the battery terminals, the capacity of the condenser and the number of discharges per second.

If the capacity of the condenser may be regarded as constant, the reciprocal of the total resistance in the steady current circuit must be proportional to the speed of rotation when the galvanometer shows no deflection, the battery P.D. being eliminated.

The speed for rotation may then be calculated by dividing a constant by the resistance in circuit.

In order to test the value of the method the author made a series of experiments determining the speed independently by an electric recording chronograph, and calculating the capacity of the condenser at different frequencies of charge and discharge. The following results were obtained from experiments on the 0·5 section of a divided microfarad mica condenser :—

Frequency determined by chronograph.	Capacity, microfarads.	Temperature.
26·969	0·49402	16·5°C.
23·375	0·49502	16
18·901	0.49530	16·5
18·904	0·49526	23
15·853	0·49613	16·5
9·6376	0·49648	23

Battery used, one Leclanché cell.

Examination of the above table shows that over a wide range of frequency from 9·6 to 27 discharges per second, the capacity varies only about 0·4 per cent. In using the apparatus to measure speeds this variation of capacity may be allowed for by constructing a graph between the reciprocal of the speed and the added resistance. This graph will be very nearly a straight line, since the capacity is nearly constant, so that only a few observations are necessary to construct it.

The two observations at a frequency of 18·9 were taken on days when the temperature was different by 6·5 deg., but as the table shows, the same value of the capacity (within limits of experimental error) was obtained at both temperatures. This is important because it shows that the change of capacity with temperature is small.

A brief description of the apparatus employed and the method of experiment may be of interest.

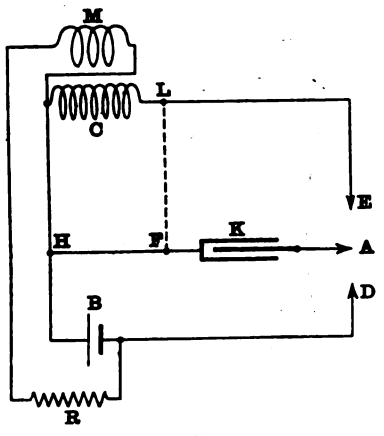

DIAGRAM OF CONNECTIONS.

The special feature of the galvanometer employed is the large ratio between the number of turns in the two windings. This enables series resistances of moderate value to be used instead of the very large and expensive resistances which would be necessary with an ordinary differential galvanometer.

This galvanometer was constructed from an ordinary reflecting D'Arsonval galvanometer by adding an extra winding of a single layer over the ordinary winding. This extra winding carries the steady current, and is wound of manganin, so that its resistance does not vary much with temperature. Both windings have a common junction to the upper suspension of the moving coil, the steady current passing out through the lower suspension, while the condenser currents flow through an extra spiral of very thin copper strip. The ratio between the currents in the two coils when equilibrium is obtained was experimentally found to be 40·708.

The commutator consists of a brass tube rotated on its axis by a shunt motor driven by storage cells, a carbon rheostat in the armature circuit giving a fine speed adjustment. At one end of the brass tube a little more than half the circumference is cut away, so that the remaining part alternately makes contact with one or other of two copper gauze brushes mounted on an ebonite block.

The connections are made in one or other of two ways as shown in the accompanying diagram.

In this diagram the two coils of the differential galvanometer are represented by M and C, and the commutator by the arrow heads D, A and E. Of these A, attached to one terminal of the condenser K, alternately makes contact with D and E, charging and discharging the condenser. B is the battery and R the

Digitized by Google

series resistance. If F be connected to H the condenser discharges pass through the coil C, but if F be disconnected from H and connected to L, the charging currents pass through C. Both methods of connection give the same value of the capacity within the limits of errors of observation. All the values given in the table were obtained with charging currents passing through C. Details of a typical observation are as follows :—

Temperature of air, 16·5 deg.	
Corrected value of R	3002·1 ohms.
Resistance of M	121·2 „
Total res.	3123·3 „

During a run of 10 minutes the galvanometer spot was kept on the zero by the fine speed adjustment. The chronograph sheet showed that the greatest variation of speed from the mean was 1 part in 3,800, and the mean time of 1,000 discharges was 63·08 seconds.

$$\text{Capacity} = \frac{0{\cdot}06308 \times 10^6}{3123{\cdot}3 \times 40{\cdot}708} = 0{\cdot}49613 \text{ mfd.}$$

The above experiments show that corresponding to every value of the speed there is a definite value of the series resistance which will bring the galvanometer to zero. As far as the adjustment is concerned the battery E.M.F. is immaterial, except that increasing it increases the sensitiveness of the arrangement.

When the apparatus is used for measuring speeds of rotation, and if great accuracy be desired, a calibration curve is easily constructed which takes account of variations of capacity with frequency; from this curve the speed of rotation corresponding to the value of the added resistance can be taken. For most purposes, however, since the capacity of the condenser is practically constant over a wide range of frequency, it will be sufficiently accurate to obtain the speed directly by dividing an easily determined constant by the total resistance in series.

ELECTRICITY IN COAL MINES.

At a meeting of the Mining Institute of Scotland, held on the 11th inst., at Dunfermline, two Papers of particular interest to electrical and mining engineers were read and discussed. The first Paper was by Mr. F. Onslow, and dealt with

"Some Considerations Affecting the Installation of Power at Collieries."

The author observed that much controversy was raging just now as to the relative advantages of the three-phase and direct-current systems for colliery work. Each system, however, possessed inherent advantages, and the problem was to select in each case the one better suited to that particular colliery. For all practical purposes each system was equally dangerous, or perhaps it was better to say equally safe, if properly installed under conditions suitable for the system selected. It was in the interests of all concerned that no time should be wasted in what might be termed "hair-splitting" as to which system was academically the safer. Apart altogether from the question as to which system should be adopted in a new colliery, where that best suited to the conditions could be selected, the present position of existing installations had to be considered. In certain parts of England and Wales some advantage might conceivably be gained by converting some of the existing direct-current systems for alternating current. In Scotland, however, the conditions were different, and attention ought rather to be concentrated upon the question of rendering existing installations safer. No doubt much could be accomplished in this direction, as many of the plants were at least from 10 to 15 years old, and desirable modifications would not only afford greater safety in working, but probably result in increased economy. Speaking generally, then, all such installations should be seriously tackled and brought up to date.

As an instance of how simply accidents might occur, he gave the following particulars, which recently came under his notice. The installation was on the direct-current system, and a serious accident nearly resulted from the live wire coming into contact with some supporting iron H-girders. Current was generated at the colliery, and two separate cables carried down the shaft to a distribution board just at the bottom. The roof at this point was supported by H-girders, and the slings supporting the cables (which were of the ordinary vulcanised class) were not long enough, with the result that the cables were held in contact with the girders. The distribution board was in a cast-iron case, which was connected to an earth-wire attached to a plate sunk in the shaft sump. It was while engaged in carrying out some alterations to the iron joists that a workman experienced a shock. Iron supports are extensively used in Scottish mines, and several accidents resembling the above, although unhappily attended by more serious results, have recently taken place owing to their becoming electrified.

The possibility of electric shock was always present, no matter what system was employed. For all practical purposes the danger was independent of voltage, as the lowest practical had been shown to be fatal. The possibility of shock could be comparatively easily eliminated in all generators, motors, and other plant by earthing, with the exception of coal cutters, which were more difficult to deal with. The greatest danger of shock, however, was from the cables, including main, distribution and trailing cables. This danger was particularly prominent in Scottish mines owing to the wet and low seams. The arrangement of the cable system was necessarily a matter which must depend upon local conditions, the principal points to provide against being shock, fire and undue deterioration. Armoured and unarmoured cables both possessed advantages, and the type best suited to the conditions might be selected. But, whichever type was adopted, great care in the installation thereof, with constant supervision afterwards, was the essential and only safe manner of dealing with cables, if fatal accidents were to be avoided. One of the main objections raised to direct-current plant was upon the score of sparking. The improvements in the design of this plant had resulted in practically sparkless commutation, even under severe overload conditions, but it could not be disputed that the danger of ignition of gas or coal-dust from this cause still existed. However, this danger was also present with alternating-current slip-ring motors, and also in a modified degree with those of the squirrel-cage or short-circuited type. Generally speaking, overload and other devices which had been proved to be reliable might be recommended, but before new devices were applied they ought to be thoroughly experimented with under practical working conditions.

The author suggested that it would be better to equip one colliery for a complete trial by experts, rather than to have partial installations in many pits. To earth or not to earth was at present a great question, and there were many advocates both for and against. If earthing were attempted it must be carried out effectively and, generally speaking, two main earth-plates should be employed, one on the surface, and one below ground in the shaft-sump or other suitable position. These two plates should be connected together by a main wire, which should run the full extent of the installation, and all electric apparatus and metallic work should be connected to it by wires of requisite section. The alternative of a number of local earth-plates was sometimes preferred, but the difficulty in this system was to obtain a good earth, so that the main wire would appear to offer on the whole the best solution.

Where winding plants of comparatively small capacity and speed were to be operated, both systems might be regarded as equally applicable, although the better torque of a direct-current motor was rather an advantage. When larger plants, requiring greater speed and more rapid acceleration and retardation were concerned, a direct-current winding motor was almost, if not quite, a necessity, although one or two schemes had been more or less perfected to allow the direct use of alternating current, but the scope of these was limited. In dealing with large winding plants an equalising system was usually necessary to reduce the demands upon the generating station or supply mains. Generally some system of mechanical storage of energy was necessary, although in the early days on the Continent accumulators were utilised. These were not then entirely successful, but reversible boosters had since been developed, and might result in a battery scheme being not impracticable, notwithstanding its high capital expenditure. A feature of such a scheme was the stand-by it afforded for week-ends, and in case of failure of the generating plant or supply mains.

Fans and pumps required motors to run them (1) at a low or medium constant speed; (2) at a high constant speed; and (3) at variable speeds. In the first case direct or alternating current motors were equally suitable. As regards the second case, alternating-current motors could be more economically constructed for high speeds, and no commutation troubles were involved, if squirrel-cage machines were employed. Frequently high speed was not possible with alternating current owing to the low frequency of the power company's supply. When variable speeds were necessary, direct current was usually preferable, as the speed variation properties of alternating-current machines could not be compared with those of direct-current. From a working point of view, direct-current coal cutters were superior to those operated by alternating current, but the latter type had proved itself quite reliable and satisfactory.

Digitized by Google

There was another possibility with regard to coal-cutting machines, as by the use of compressed air these might be operated from an electrically-driven compressor. Such a combination offered many possible advantages, especially where a number of cutters were employed in a small area, as these could all be supplied from one compressor, thus securing the advantage of compressed-air cutters, and the economy of electrical transmission.

DISCUSSION.

Mr. MUIR (Bowhill) said, with reference to the generation of electricity in connection with exhaust steam, that they had such a provision at Bowhill, and they found it a very valuable acquisition indeed to the colliery. Its value was all the more marked in connection with the winding engines. He thought there was considerable room for improvement on the gas engine, and while he believed there was likewise a necessity for improvement in the steam engine, he thought the latest combination with exhaust steam turbines would be very successful indeed. His own experience in connection with the distribution of power had been entirely with the three-phase system, and he homologated the view that had been expressed by Mr. Robert Nelson, H.M. Electrical Inspector of Mines, in his recent valuable Paper "Electricity in Mines." He had no doubt whatever that an installation, properly installed, of the three-phase system, and armoured continuously throughout, would make for safety. He believed, in regard to thin seams, that it was a great consideration whether one would not adopt continuous current in consequence of the difference in height required for the three-phase motor. He was confident, however, that electrical engineers would themselves soon overcome that objection. One difficulty in taking power from power companies was the fear that sometimes their power might not be suitable for everything in connection with a colliery. Both in the alternating and continuous-current systems there was usually a considerable amount of trouble with the switches. That was one thing in which unquestionably there was a good deal of wear and tear, and any person who could invent a switch that would be satisfactory for all conditions about a pit would be conferring a very great boon indeed on colliery owners. One of the most important things in connection with alternating current was a proper controller, and his own opinion in that matter was that the controller ought to be on the water-tight principle.

Mr. SAM MAVOR (Glasgow) said that in the past the discussions on Papers such as this had been left largely to electrical people who were personally interested in one or other of the systems. He had the feeling, however, that it would be much more useful if colliery managers who had experience of the systems would enter into the discussions.

The PRESIDENT (Mr. Robert M'Laren) said he fully endorsed that observation, and so as to furnish time for consideration of the Paper he proposed to adjourn the discussion until the next meeting.

The second Paper, which was entitled

"POWER PRODUCTION AT COLLIERIES, WITH SPECIAL REFERENCE TO GAS POWER AND ELECTRICAL CENTRALISATION,"

was jointly contributed by Messrs. R. Crawford and H. Moores. The authors at the outset pointed out that the growing need for economy made the subject of power cost one to which the colliery manager must devote attention with a view to generating and transmitting this power in such a manner as would ensure the highest possible efficiency. Of late years the adoption of electricity as a secondary power for pumping, ventilation, haulage, coal-cutting, &c., had greatly increased the efficiency of mining power plant by displacing small steam units, thereby considerably reducing colliery consumption. Much good work had also been done by the introduction of low and mixed-pressure turbines, so arranged as to utilise the large amount of exhaust steam from the winding engines, and to a less extent from haulage and other engines about the colliery. Examples of this kind, the authors mentioned, were not wanting in Fife, and mention might be made, say, of the Fife Coal Co., which had six mixed-pressure turbines at work, of a total capacity of 5,800 H.P.

Whilst a good deal of attention had been devoted to electrical centralisation of power at large collieries by means of exhaust steam turbines, it was found that much higher economies could be obtained by converting the fuel into gas for the purpose of driving gas-engine electrical generating sets, from which energy would be transmitted at high-tension to the machinery at outlying pits. It was undoubtedly in this direction that colliery managers must look for the highest possible economies.

The following was an estimate for a proposed 5,000 kw. gas-driven central electrical generating station for a colliery. Assuming coal of an average quality of 13,000 B.Th.U. per lb. and a gas-producer efficiency of 75 per cent., each pound of coal gasified would yield 9,750 B.Th.U. available in the engine cylinder. A large engine would work on three-quarter load on a consumption of about 8,000 B.Th.U. per brake-horse-power-hour, and there was at least one case on record of an engine having performed a continuous non-stop run of over two years on a consumption of only 7,892 B.Th.U. per brake-horse-power. In the present instance, however, the writers took the consumption as 9,350 B.Th.U. in order to cover all contingencies, such as ultimate loss of compression due to piston wear, &c. With a dynamo efficiency of 90 per cent., this was equivalent to 1·42 lb. per kilowatt-hour at the switchboard. The capital outlay involved in a gas-power station of 5,000 kw., comprising Mond gas-plants with ammonia recovery apparatus, multi-cylinder gas engines of, say, 1,000 kw. each, direct-coupled generators, buildings, foundations, &c., was approximately £17 per kilowatt, or a total of £85,000. Such a plant, working on a load factor of 60 per cent., which could easily be obtained in most collieries, and exceeded in the case of wet pits with heavy pumping—would generate 21,600,000 units per annum. The coal consumption for 21,600,000 units at 1·42 lb. per unit would be 13,692 tons per annum, costing £1,369. On this basis the cost of production was found to be 0·20d. per unit at the switchboard, from which the bye-product revenue must be deducted. Assuming a yield of 95 lb. of sulphate per ton of coal gasified, the recovery would be 585 tons per annum. This represented, at £11. 10s. per ton, a sum of £6,727, while the yield of tar might be expected to realise a further £384. On deducting these amounts from the gross cost, the net cost of electricity would be found to work out at the very low rate of 0·12d. per unit. This would be still further reduced to 0·11d. per unit if screen refuse were used instead of duff. There did not as yet appear to be any reliable data available regarding the total inclusive cost of power from a combined colliery installation of non-condensing piston engines and turbines, but the writers believed that the figure mentioned above, namely, 0·12d. per unit, represented a clear gain of not less than £19,898 per annum on an outlay of £85,000. With refuse shale as fuel, the gain would be correspondingly greater.

In conclusion, the authors contended that a gas-driven central electrical power station for a group of collieries was the ideal arrangement, where circumstances admitted of the outlay which such a scheme involved. There appeared to be no doubt that many such would spring into existence during the next few years with a view to using to the best advantage the heat possibilities of the coal consumed.

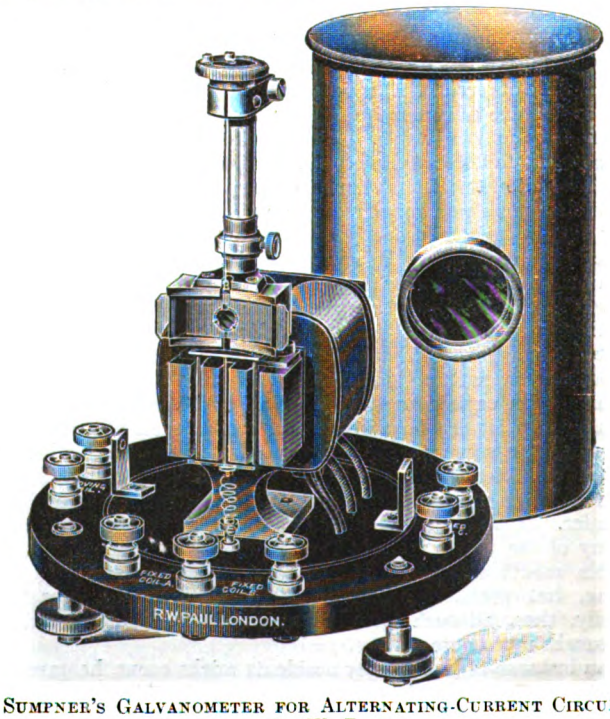
This Paper is to be discussed at the next meeting of the Institute.

PHYSICAL SOCIETY.

At the meeting held on June 10th, Prof. H. L. CALLENDAR, F.R.S., President, in the Chair, a Paper on

"A Galvanometer for Alternate-Current Circuits,"

by Dr. W. E. SUMPNER and Mr. W. C. S. PHILLIPS, was read by Dr. Sumpner. Tests of effects due to change of current, such as induction



SUMPNER'S GALVANOMETER FOR ALTERNATING-CURRENT CIRCUITS, BY R. W. PAUL.

phenomena, are often hard to carry out because the ballistic galvanometer is not sensitive enough. Alternate current tests are still less satisfactory owing to special difficulties. The vibration galvanometer overcomes only a few of these difficulties. It must be adjusted to resonance for the best effects, and its indications vary with current frequency. The sensitiveness of ballistic galvanometer tests can be

Digitized by Google

greatly increased by the use of some form of mechanical commutator by means of which a crude form of alternate current is produced. A better method would be to generate the current in the usual way if a suitable instrument existed. The galvanometer here described is the result of an attempt to construct a measuring instrument by means of which inductances and capacities can be compared by bridge methods as accurately as it is possible to compare resistances. The instrument (which is illustrated herewith) is like a moving coil galvanometer in almost every respect, except that its field is due to a specially constructed electromagnet excited by an alternating voltage. This voltage V is applied to a winding of m turns of the electromagnet, and the core flux N is such that $V = rA + m\dot{N}$, where r is the resistance of winding and A the current traversing it. The coil and electromagnet are so designed that for currents of the frequencies used the value of rA is negligible in comparison with V. The rate of change of N will therefore be at each instant a measure of V, whatever the permeability or hysteresis of the core. The instrument has a laminated electromagnet formed of stampings of two kinds—a rectangular portion with two straight limbs forming the core of the electromagnet, and a specially shaped stamping between the poles. The moving coil of 50 turns swings in a narrow gap separating the stampings, in much the same way as in a permanent magnet instrument. On the limbs of the magnet are windings of 200, 2,000 and 4,000 turns. The iron will not be too strongly magnetised if the winding used contains 20 turns per volt on 50 ~ circuits, but the instrument is so sensitive that such excitation will only be needed for exceptional tests.

If a voltage, V, be applied to one of the field coils of m turns, and if the same, or another, field winding of n turns be joined up, through a condenser of K microfarads, to the moving coil, the torque acting on this moving coil will be a measure of $Kn(V/m)^2$; *i.e.*, the deflection is proportional to the square of the voltage. By suitably choosing K, m and n, the voltmeter may be used over a large number of ranges. Thus with the instrument shown a deflection of 200 mm. on a scale at 1 metre distance can be obtained either for 200 volts or for 20 millivolts. The deflection is independent of frequency and wave-form if the field winding to which the voltage is applied has a resistance negligible in comparison with its impedance. Thus with $m = 4{,}000$ and $n = 200$ it was found that the value of V^2 required to give a certain deflection was independent of frequency between 50 ~ and 100 ~ but at 25 ~ it was 6½ per cent. less than 50 ~. At any fixed frequency the deflection will always measure KV^2. The instrument may be used with great advantage to compare inductances and capacities by the ordinary bridge methods, the working conditions being (i.) the alternating voltage V applied to the field coil of the instrument must also cause the current in the bridge conductors, (ii.) the alternate current in the bridge must be made in phase with the voltage V by the use of suitable non-inductive resistances, (iii.) the moving coil must be placed directly across the bridge.

The balance can be adjusted with ease to 1 part in 10,000 when the voltages set up in the coils or condensers are of the order of 1 volt. When a balance of great precision is needed, the minute E.M.F., e, induced in the moving coil by the alternating field of the magnet tends to cause a small deflection disturbing the balance. When the moving coil circuit is non-inductive, the current due to e will be in phase with e and in quadrature with the flux so that the corresponding deflection will be negligible. But in all cases any effect due to e can be accurately eliminated by working to a false zero. As illustrations of the behaviour of the instrument, the results of tests are given on the measurement of the mutual induction of coils, the comparison of capacities, and the measurement of specific inductive capacity.

Mr. A. CAMPBELL expressed his admiration of the galvanometer and in particular of the ingenious method of connecting it with a condenser when voltage is to be measured. He remarked that the instrument was very similar in construction and use to that used by earlier experimenters. Stroud and Oates ("Phil. Mag.," 1903) described such a galvanometer and showed how sensitive it was for testing condensers by Anderson's method and for other purposes; and Terry ("Phys. Review," 1905) used a similar one for accurate comparisons of condensers. Abraham ("Comptes Rendus," April, 1906) described another in which the false zero was got rid of by a compensating arrangement. With regard to vibration galvanometers, there was no difficulty in keeping them in tune on any reasonably steady alternating circuit. In the bridge methods illustrated in the Paper, a double adjustment was necessary when a vibration galvanometer was used, and in general an evaluation of effective resistance or leakage resistance could be made simultaneously with the measurement of inductance or capacity. He asked the authors if this double adjustment could be entirely dispensed with when the quadrature galvanometer was used. It would be interesting also to know how the instrument would work with non-sinusoidal wave-forms in a case where the balance depended on the frequency.

Mr. W. DUDDELL asked if the authors could supply more numerical data so that the instrument could be compared with other galvanometers of similar design. He pointed out that the tests were simplified owing to a double adjustment being unnecessary.

Mr. IRWIN thought that with small modifications the instrument would be useful for tests other than those described in the Paper. It might, for example, be used in determining the resistance of electrolytes. He pointed out that errors might arise due to a small amount of magnetic material in the moving coil.

Dr. SUMPNER stated, in reply to Mr. Campbell and Mr. Duddell, that the object of the special shape of pole piece was to increase the impedance of the exciting coil. Electromagnet galvanometers were not new, but the special mode of controlling the magnetic flux by the applied voltage was novel. The behaviour of the instrument was a direct consequence of this device. The vibration galvanometer responded to a voltage irrespective of its phase, and hence in some tests troublesome double adjustments were needed. This was not the case with the new instrument in regard to any of the tests described in the Paper. The current taken by the instrument could easily be calculated from data given in the Paper. In reply to Mr. Irwin, the author said that the small deflection due to magnetic impurities in the moving coil could be eliminated in all balance tests by using a false zero method. In deflectional methods the effect could be rendered negligible by reducing the voltage exciting the field, and using a moving coil current of correspondingly increased strength.

Mr. PHILLIPS stated that the present Paper was preliminary to a more detailed account of the work which had been done with the instrument. In reply to Mr. Irwin, he stated that it was proposed to make use of the instrument to measure the specific inductive capacity of materials and the resistance of electrolytes.

Mr. A. E. GARRETT read a Paper entitled

"Positive Electrification due to Heating Aluminium Phosphate."

In 1904 Dr. R. S. Willows and the author communicated to this society the results of some experiments on the halogen compounds of zinc, in which it was shown that those compounds when heated ionised the air around so that both positively and negatively electrified bodies gradually lost their charge. Work in this direction was continued, and the results obtained showed that a large number of inorganic compounds possess properties of a like nature to the above. In 1907 Sir J. J. Thomson found that chlorides, phosphates and nitrates give off an excess of positive ions when heated, and he incidentally discovered that aluminium phosphate was most active in this direction. As many of the substances previously examined are known to be unstable (and hence the ionisation produced may be the result of chemical change), while aluminium phosphate, on the other hand, is a most stable substance, it was thought that an investigation of the ion producing properties of that compound would be of interest. The apparatus was arranged so that the salt could be heated to the desired temperature (900°—1,300° C.) on a strip of platinum foil. The pressure could be reduced as required. For most of the experiments a sensitive galvanometer was used as recording instrument. With the usual distance between the electrodes (0·5 cm.) it was found that a difference of potential of 60 volts was sufficient to obtain a saturation current with the positive ions. The way in which the current varied with the time when the saturation voltage was applied was first investigated. For the first half-hour the current was somewhat irregular. This was found to be due to the water present in the salt. The current for the first hour or two appears to be largely influenced by the surrounding gas. Neglecting the preliminary effects due to water, the decay of the current with the time can be represented by a curve having the general formula $A(e^{-\lambda_1 t} - e^{-\lambda_2 t}) + B(1 - e^{-\lambda t})$. The current finally obtained depends almost entirely upon the salt itself. After five or six hours' heating, no further change takes place in the current obtained under fixed conditions of temperature and pressure. A temporary increase, however, can be brought about by moistening the salt, and also by passing a discharge from an induction coil through the tube for about ½ minute. When the salt is insulated and heated for some time, an extraordinarily large current passes when the field is first put on. This effect increases with the time up to about 10 minutes, after which any longer insulation causes no increase of the initial current. With the salt in the final steady state the conditions were suitable for experiments on temperature and pressure effects. It was found that for every temperature tried there was a certain pressure at which the current obtained was a maximum, and the higher the temperature the lower was this pressure. The currents obtained with constant pressure and variable temperature indicate that the relationship between the rate of production of positive ions and the absolute temperature can be represented by the Richardson formula $a\theta^{\frac{1}{2}} e^{-\frac{Q}{2\theta}}$. By using a quadrant electrometer in place of the galvanometer, it was found at pressures of 0·01 mm. that some positive ions are ejected with a velocity of the order 10 cm. per second; and other experiments showed that the ions at very low pressures and acted upon by small electrostatic fields moved with great velocity, so it was thought that this substance could be made use of as a means for rectifying alternate currents. It was found that it could be so used. The values of l/m obtained by Thomson's cycloid method indicate that the smallest of the positive

Digitized by Google

ions present possess a mass comparable with that of the hydrogen atom. Many of the results obtained, in particular (*a*) those with varying pressures and constant temperatures, (*b*) those at atmospheric pressure in which after removal of all free ions by a field sufficient to produce a saturation current, a current of equal values for ions of both signs was found at an electrode placed behind that on which the saturation voltage acted, and (*c*) the loss of charge of a Faraday cylinder when screened from the action of free ions, indicate that one of the products due to heating aluminium phosphate is in the form of neutral pairs or doublets which afterwards split up into negative and positive ions.

AN IMPROVEMENT IN SINGLE-PHASE ALTERNATORS.*

BY PROF. C. PICHELMAYER.

Summary.—Means are described whereby the dangerous pressures, induced in the rotors of single-phase alternators by the inverse rotary field, can be avoided and the factor of safety of working of these machines made equal to that of polyphase machines.

In various single-phase installations which have been erected during recent years, it has been noticed that the exciting windings of large single-phase generators—and more especially of turbo-driven sets—have frequently broken down, due, it has been suggested, to high pressures being induced in them. Since these breakdowns have always necessitated the unit in question being shut down, it will be seen that they seriously disturb the working of the system. The origin of this trouble, therefore, was rapidly investigated and prevented.

Below an arrangement is described which fulfils this object completely, and was the subject of an Austrian patent (11/12/08), which, however, was abandoned in the meantime on account of difficulties appearing in its practical application. The arrangement consists in having a cylindrical rotor for the

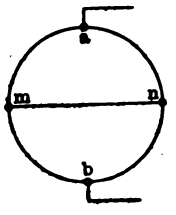


Fig. 1.

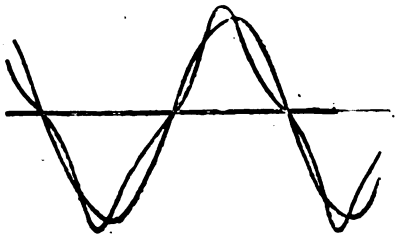

Fig. 2.

magnet wheel of single-phase generators, the rotor being provided with an ordinary continuous-current winding. The terminals are connected as usual to two diametrically opposite points, *a* and *b*, in a bi-polar arrangement (*see* Fig. 1), whilst two other points, *m* and *n*, 90 deg. from *a* and *b*, are electrically connected to one another. This cross-connection has no effect on the exciting circuit, being joined to two equi-potential points, but forms a very good damping circuit in conjunction with the exciting winding. The action of the two-phase damper will be at once clear when the armature reaction of the generator is explained by means of the theory of two oppositely rotating fields, which can be used here with advantage. (*See* article by H. Brühn, "Betrachtungen über die in der Erregungswicklung von Einphasengeneratoren induzierten Spannungen," "Zeit. für Elec. und Masch.," January 3, 1909. An abstract of this article appeared in The Electrician, Vol. LXIII., p. 20.) If we split up the pulsating stationary field, produced by the single-phase current in the stator, into two oppositely rotating fields, each of half the magnitude of the stator field, then the rotary field revolving with the rotor—being relatively at rest to the latter—will have the same effect as the armature flux of an ordinary polyphase machine. This component, therefore, will not induce E.M.F.s of any great magnitude in the exciting winding. On the other hand, the inversely rotating field can induce considerable pressures in the rotor winding. With the same number of turns in stator and rotor and similarly disposed windings, this pressure produced by the inverse field in the rotor winding will—owing to its relative velocity being twice that of the main field—be twice as great as the reactance pressure induced in the stator-winding by the component revolving with the main field—thus it may reach 50 to 60 per cent. of the terminal pressure. Now the latter pressure will be about 40 to 50 times the exciter pressure with the same number of turns in stator and rotor, so that the pressure induced in the rotor winding may become 20 to 30 times the exciting pressure, which, of course, is by no means safe. This happens with normal working at normal load where the reactance pressure of the armature is 25 to 30 per cent. of the terminal pressure, as assumed in the above example. In case of short-circuit, this pressure will become much more dangerous.

The inverse field not only produces these dangerous pressures, but also distorts the current and pressure waves of the generator, for this field exerts a strong reaction on the exciting circuit and induces in the latter a current of double the frequency of the stator current. This in its turn reacts on the stator winding and produces a third harmonic current, as is well known from the theory of armature reaction.

Now the inverse field is only partly damped by the exciting circuit along *ab*. When, however, *m* and *n* are short-circuited practically a complete damping of this component takes place. This can be well illustrated by means of the oscillograph—the curves of pressure and current being strongly distorted when the cross-connection is open, but quite good when the latter is closed.

Experimental Results.—The experimental machine consisted of a single-phase stator and a continuous-current armature of

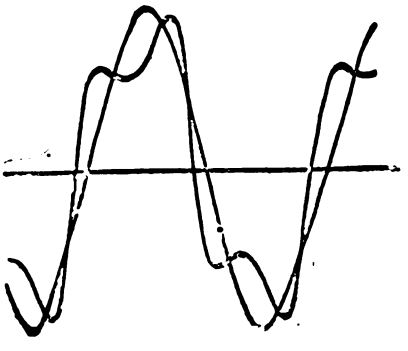

Fig. 3.

3·5 kw. output. The air-gap was 3·5 mm. There were four slip-rings connected to the points *a*, *b*, *m* and *n* respectively (Fig. 1). Most of the tests were taken with a stator current of 28 amperes, whilst the rotor was excited with 36 amperes at 22 volts. The number of turns in series on stator and rotor were 112 and 204 respectively, so that the ratio of the stator to the rotor ampere-turns was $\frac{112\times 28}{204\times 36}=\frac{1}{2\cdot 34}$. When the cross-circuit *mn* was open the pressure across these points was 80 volts with 28 amperes in the stator, and this pressure was found to be practically proportional to the stator current. On closing the cross—or damping—circuit *mn* a considerable compounding effect was observed, which at full load reached about 5 per cent. Under these conditions also the short-circuit characteristic was 15 per cent. higher than with the cross-circuit open—*i.e.*, normal.

Amongst the oscillograms taken, Fig. 2 shows the pressure curves on non-inductive load with and without the cross-connection (note the distorting effect when no damping is present). Fig. 3 shows similar curves for inductive load. The cross-circuit pressure and current were also shown to be of twice the frequency of the main current.

It was thus proved that the introduction of the damping circuit led to three useful results: (1) Compounding effect, (2) prevention of excessive pressure in the exciting winding, (3) suppression of higher harmonics in the terminal pressure wave.

* Abstract of an article in the "Electrotechnische Zeitschrift."

Digitized by Google

Since, moreover, the whole exciting winding is used as a damper it will be seen that the loss thus created is very small. For example, if A_s denotes the ampere-turns per pole-pitch in stator, then at full load the ampere-turns of exciting winding will be 3A to 4A_s, whilst the ampere-turns damped are practically $\frac{1}{2}A_s$. Hence the loss due to the damping current in the exciting winding will be only $\frac{1}{36}$ to $\frac{1}{64}$ of the excitation loss, which can be neglected.

With regard to the adoption of this device, it has to be pointed out that the continuous-current winding is not always desirable for turbo-rotors, though for slow-speed machines the same difficulties do not occur. The arrangement can also be used in converters to keep down pulsations in the resultant field, in which case the exciting winding is made up of a continuous-current winding with cross-connection.

The same effects as above, though connected with greater losses, can be produced by a Hutin-Leblanc damping winding. Preferable to this, however, is a complete squirrel-cage winding spread over the whole rotor. This is the means adopted on the generators of the New York, New Haven & Hartford single-phase railway to prevent the dangerous rotor pressures. Such improvements as the above make the single-phase generator practically equal to the polyphase, and the author is of the opinion that the single-phase output of a given type fitted with either the damping arrangement or short-circuited winding is equal to the polyphase output of the same machine.

A GRAPHITE CATHODE DISH.*

BY J. W. TURRENTINE.

Summary.—Simple graphite electrodes are described, which are designed for use in the place of platinum as insoluble electrodes in electrochemical experiments. An account is given of preliminary experiments with a graphite dish intended to supplant in some forms of electrochemical analysis the Classen platinum dish. The dish is recommended for electrochemical separations and for analyses where great accuracy is not required.

In conducting a laboratory course in applied electrochemistry, one devoted largely to that phase of electrochemistry which has to do with solutions and the electrolysis of solutions, the need has been experienced for some good material which could be substituted for platinum in the construction of insoluble electrodes. In the Cornell laboratories, for ordinary work, graphite has been substituted. Trouble was experienced with this material on account of the fact that it was porous and absorbed the solutions in which it was used, and, therefore, could not be cleaned readily. This prevented its use in experiments where impurities might interfere with the desired reaction. Also, at high current densities the graphite electrodes showed a tendency to disintegrate and to fill the solution with clouds of finely divided graphite powder. This was due, possibly, to the discharge within its pores and beneath its surface of gases which forced off the surface particles. A further objection was found in the graphite's propensity for rubbing off and smutting.

After experimentation to determine a means of preventing the absorption of solutions by the graphite, it was found that if the graphite electrodes were treated while hot with molten paraffin, in amounts which are readily absorbed by them, the surface of the graphite acts as though it were greased, and is not wetted by aqueous solutions. Because of surface tension phenomena, the pores are not entered by the solutions. The treatment with paraffin furthermore reduces to a minimum the inclination of the graphite to rub off, so that it is rendered quite clean, and it may be handled freely without smutting.

In the laboratory of Wesleyan University we are now using graphite electrodes made from Acheson sheet graphite of 0·5 cm. thickness. The sheet is cut into pieces which are 15 cm. by 2·5 cm. in dimensions. One end is copper plated, and a copper wire about 20 cm. long is twisted around this end and is soldered in place to the copper plate. To protect the exposed metal at this point from fumes, the end of the electrode is covered with a light coating of varnish. The graphite is then paraffined while hot.

We were thus enabled to supplant very satisfactorily by the use of paraffined graphite the platinum sheet electrodes heretofore used in ordinary experiments in laboratory work. In electrochemical analysis, however, and separations, expediency still demanded the use of the Classen platinum dish. The use of a graphite dish as a substitute for the platinum dish need not be confined to pedagogic electrochemistry, but should also find an extended use in commercial laboratories.

Encouraged by the success of the paraffined graphite electrodes, a graphite dish was prepared from a 4 in. cylindrical stick of Acheson graphite. This dish was turned out on a lathe. Graphite was chosen as the material of which to construct the dish, because in it we have a substance which is at once a good conductor of the electric current, is cheap, is light in weight and is non-attackable by solutions. The porosity of the graphite may prove to be the greatest obstacle in the way of the dish becoming a success when employed in the most accurate analysis. The degree of porosity is expressed numerically as the quotient obtained by dividing the difference between the real and apparent specific gravities by the real specific gravity. The apparent specific gravity is that obtained when interstices of the graphite are kept free of the liquid in which the determination is being made. This is accomplished by coating the sample lightly with shellac. The real specific gravity is found after the air has been removed from the pores of the sample by greatly reducing the pressure over the immersing liquid. When the suction is released the evacuated pores become filled. The average of several determinations gives the porosity of graphite at about 0·25. Such a degree of porosity would seem to make this substance an impossible one of which to construct a dish designed for such purposes as is this one. The paraffin, however, is very effective in preventing the absorption of solutions into the pores. That the latter are not entirely filled by the paraffin is shown by the fact that alcohol is able to penetrate the paraffined graphite fairly readily. It is highly probable that while aqueous solutions do not enter the interstices, aqueous vapor does and condenses there to a certain extent; so it may be necessary eventually to fill these entirely with paraffin by the evacuation method used in the specific gravity determination.

The purity of graphite is high, and therefore it is improbable that any contamination of solutions can possibly result from its use. The experimental dish was prepared for use by first burnishing on a revolving steel-wire buffer, which served to remove all dust and gave the surface a somewhat polished appearance. The graphite still rubbed off on the fingers, but to a much lessened extent; after treating with paraffin it no longer rubbed off at all.

The dish was warmed in a hot-air bath to a temperature of about 110 deg., and, while still hot, molten paraffin was applied with a brush until it was no longer absorbed readily, but remained visible on the surface. The dish was then returned to the oven, several sheets of filter paper were placed under it and the bath was maintained at the temperature of 110 deg. for several hours. In this way the excess of paraffin was drawn off, by gravity and capillary action, into the filter paper. After this treatment the surface of the graphite appeared quite dry. The dish was then reburnished.

The preliminary experiments conducted with this dish gave such very promising results that two other dishes were obtained. These are much lighter in weight, weighing, respectively, 38 and 32 grams after having been paraffined. Their capacity is 200 c.c. In dimensions they are 9·5 cm. in diameter across the top and are 5 cm. deep.

The method was adopted of drying, after washing with distilled water, by holding the dishes by means of crucible tongs directly over the smokeless flame of a Bunsen burner, moving them around during the drying so that the heating would be uniform, and then cooling in a desiccator. This extremely crude method was justified by its rapidity and surprisingly satisfactory results.

A number of determinations of efficiency were then made by electrolysing an acidified solution of copper sulphate contained in a graphite dish in series with a copper coulometer filled with a portion of the same solution. Copper anodes were employed in both cells and a copper cathode in the coulometer. A current of 0·1—0·16 amperes was passed and the electrolysis was continued for about one hour in each run. The results were generally good, but an occasional result failed signally to agree with the theoretical value. As a check on the method, a Classen dish, containing a similar solution and copper anode, was also placed in the circuit; this cell was worked in series with the other two. The results, as a whole, were hardly as good as those obtained with the graphite dish, and, like those, an occasional one was bad.

The results obtained for the graphite dish are for the most part lower than those obtained with the platinum dish. It appears that there is perhaps some loss in the weight of the dish itself in drying, which causes the low results. Therefore, the method of drying directly over the flame will be abandoned and, instead, the dishes will be washed thoroughly with distilled water and then dried rapidly in a stream of warm dry air.

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fiftieth issue of the Supplement is published (Gratis) with the current number of "THE ELECTRICIAN."

The "INDUSTRIAL SUPPLEMENT" is a comprehensive record of developments in Electrical Plant, Machinery, Apparatus, Accessories, Sundries and Materials, and of their proved suitability for various Industrial purposes.

The "INDUSTRIAL SUPPLEMENT" is holed for filing or hanging, and filing covers can be supplied for holding 6 or 12 issues.

SPECIAL NOTICE.

NOW READY.—Vol. LXIV. of "THE ELECTRICIAN" (1,085 pages.) bound in strong cloth. Price 17s. 6d.; post free, 18s. 6d. Now ready Cases for Binding. Price 2s.; post free, 2s. 3d.

A complete set of "THE ELECTRICIAN" can be supplied. A number of odd volumes and some odd old back numbers, to help in making up plete sets, are also available.

CONTINUOUS RECORDS.

As to the advantage of records in electricity supply there can be very little doubt, though there may be some question as to the extent to which they should be adopted. Much wisdom was shown (possibly unintentionally) when it was decided that electrical undertakings working under Provisional Orders should be required to make public the detailed costs at which electrical energy was generated. This resulted in the publication of a great deal of useful information, and we do not doubt that the general accessibility of these data has stimulated a certain competition between central station engineers, and has led to the highest possible efficiency. Probably this course has led to the very low costs which are general in this country, and which place us at an advantage over many countries abroad in regard to electricity supply.

Annual records, however, are not all that is required, as the interval is too long for many purposes. At the recent meeting of the Incorporated Municipal Electrical Association, Mr. GEORGE WILKINSON, of Harrogate, advocated continuous records of costs and of steam consumption. The opinions, however, of those present seemed to be somewhat divided. For example, Mr. C. H. WORDINGHAM thought that central station engineers were becoming meter maniacs, with an unnecessary profusion of records, and that careful tests at longer intervals were more important than daily tests, which could not be nearly so accurate. Mr.

Digitized by Google

Mark Ruddle, of Dublin, also thought that the keeping of detailed records in large stations was impracticable, owing to the time involved in their preparation, and that the time of the staff was better spent in inspecting the plant and seeing that it was in proper working order.

Although records are easy, and give the desired result with a minimum of trouble when it is a question of electrical measurements, the mechanical engineer finds himself in a much less happy position when he attempts a continuous record of the performance in the boiler house. To ascertain the total quantity of coal and of steam over a long period is a simple matter, but what it is really desirable to know is the rate of usage rather than the total usage, although the latter is also highly necessary as affording a more reliable figure in the long run. The total does not, however, show how the working varies from day to day. Unfortunately, to obtain a continuous record of the rate of using coal is far from easy. The capacity of the boiler produces a difficulty at once, and leads to the likelihood of introducing serious errors over short periods, even as regards the water. It is almost impossible to ensure the standard quantity of water in a bank of boilers at the end of each days's run, and, therefore, the measurement of the steam in some form or other seems preferable to the measurement of feed water. Coal consumption in particular is a difficult matter to handle from the point of view of continuous records, and it looks as if some indirect method of attack should be adopted. In the case of hand firing, extreme regularity cannot be expected. With mechanical stoking the outlook would seem more hopeful, but at best it would appear that the determination of coal, as coal, must depend upon the measurement of a quantity over a more or less long interval of time, which is not what is desired. It is the difference between the voltameter and the ammeter.

On the particular question of the desirability of continuous records, we do not think there can be any question that they are really desirable if the cost of their production is not too high. Probably very few engineers have an exact idea how the cost of production varies at night on low loads, as compared with production in the daytime. Mr. C. E. C. Shawfield, of Wolverhampton, mentioned that he had obtained results showing that an increased production of units at night caused a reduction in the coal consumption, but he did not care to put forward this result without some hesitation. Evidently, if electrical energy is produced so uneconomically at night by many stations, the addition of a street lighting load may cause practically no difference in coal consumption, and should enable street lighting to be effected at times of light load at an extremely low cost. We do not suppose that such a doctrine, as enunciated by Mr. F. E. Ayton, of Ipswich, will meet with approval from our gas friends, and they may attempt to show that it is wholly illogical. There is, however, nothing illogical in it if the facts are as suggested by Mr. Shawfield. It is in questions of this kind that continuous records would prove of very great utility; and so long as the true perspective of the subject is not lost sight of we think that much will be gained by cultivating this aspect of electrical generation.

ELECTRIC CABLES.*

ELECTROLYSIS.

BY F. FERNIE.

(*Concluded from p. 383.*)

Summary.—The author first considers the general phenomena of electrolysis as observed in the neighbourhood of electrical networks. He then discusses in more detail the corrosion of lead-covered cables and armoured cables, and the effectiveness of earthing. Another cause of deterioration is electric osmose, which causes an accumulation of moisture at the negative conductor if there is any flow of current through the insulation. Finally, the causes of faults and measures for preventing them are considered. Faults may be classified into those of manufacture, those caused during laying, and those developed after the cables are laid. The last class is due to a number of causes, such as mechanical injuries, electrolysis and electric osmose, chemical action, overloading and decentralisation, high temperature, abnormal pressures and static discharges. Another cause of trouble is the accumulation of gas in manholes, causing explosions. The various ways in which gas may accumulate are considered and the remedies to be applied.

Manhole Explosions.

Manhole explosions are caused when an accumulation of inflammable gas is ignited by an arc on a faulty cable, or by sparking generally. It is possible that gas may be exploded by the hydrogen which takes fire when sodium or potassium combine with water. It is well known that metallic sodium and potassium are deposited on a faulty negative cable by the electrolysis of the soil. The presence of these metals in a duct or manhole therefore implies a leaky cable or fitting, and hence this form of ignition is really only a special case of the general one quoted above. It is conceivable that a spark might be produced in a manhole by some stray current from an outside source, or from a fault current from somewhere else on the network, travelling along the lead of a cable. When a cable is used for high potential alternating currents the lead may spark to earth if it is not earthed properly, or if a bond has been melted or broken; this is a consequence of the condenser action of the cable.

The gas in the manhole may be the result of leakage from a faulty gas main, or it may be an inflammable gas generated by the decomposition of a cable dielectric or covering through heating, or it may be an accumulation of marsh gas, CH_4, the miner's "fire damp." The latter is always a product of the decomposition of vegetable matter in soil, and hence may easily be present in underground ducts; it may also come from drains and sewers. The spontaneous combustion of phosphoretted hydrogen in air may be sufficient to ignite accumulation of other gases. PH_3 may be formed by the action of lime on animal phosphates existing in road refuse. Coal gas is only explosive when mixed with air in certain proportions, the limits being 5 to 25 per cent. of coal gas. About 10 per cent. coal gas gives the most explosive mixture.

The gas given off by vulcanised bitumen, or the bitumen round a "solid" laid cable, is probably a mixture of several hydrocarbons. The resin in a paper-insulated cable may also give off some explosive gas, such as olefiant gas (C_2H_4), but probably not to a sufficient extent in practice to cause an explosion, as a fault on a paper-insulated cable is generally very local, and only a small portion of the paper insulation is destroyed. Marsh gas mixed with about 10 times its volume of air forms a powerfully explosive mixture.

Bare copper strip in culverts has earned a bad reputation for explosions. The gas in this case must come from an outside source—*i.e.*, it must be coal gas or some gas generated from decomposing matter in the soil. This is the most likely case for the firing to be caused by sodium or potassium, as accumulations of alkali salts often appear in concrete culverts on the insulators; these metals when combining with water might also generate sufficient hydrogen to form an explosive mixture. If an arc is formed between two adjacent strips of copper of opposite polarity in a culvert it may travel along the copper for a considerable distance, travelling in such a direction as

* Copyright. All rights of reproduction reserved.

Digitized by Google

to increase the area of the circuit of which it forms a part. Such an arc may then fire gas in a manhole some distance from the point where the arc was formed. Its path may be traced by the little beads of copper formed on the strip. Such an arc may be prevented from going far by inserting dividing fillets of slate between the strips of opposite polarity in the straining boxes.

Vulcanised bitumen cables drawn into earthenware ducts are probably the most frequent cause of explosions, and this is because this class of duct is the very worst for such cables, and hence faults are more frequent with this combination than with others, and where faults are frequent there is naturally a great probability of explosion. Also a vulcanised bitumen cable is likely to generate inflammable gases in greater bulk, and at a greater rate, when overheated than other types of cables. Some disastrous explosions have occurred in Manchester, within the last few years, which have been mostly attributed to the volatilisation of the bitumen surrounding the cables and the formation of an explosive mixture.

In a report by Mr. J. A. Bell to the gas and electric lighting committee of the Aberdeen Corporation,* on the culvert explosions in that city, it is stated that the mere sudden expansion of air, caused by a short-circuit will blow up manhole covers. "Those experiments tended to show that the explosions were in many cases brought about by the sudden heating and consequent expansion of the air in the manhole or culvert." On the other hand, violent short-circuits have occurred in manholes and culverts that have *not* blown up any covers, but as direct experiment has proved its possibility, the fear of its occurrence can never be entirely absent. Very curious things happen sometimes in connection with explosions

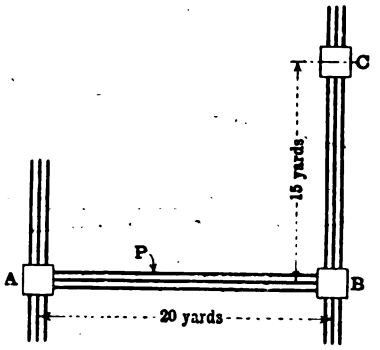

FIG. 1.

in mains. Cases have occurred where starting at some fault, a series of some twenty manhole covers have been blown up, one after another along a whole street. The ducts and manholes in these circumstances were probably all full of a fairly strong (over 15 per cent.) mixture of coal gas and air, and this burned back through the ducts causing an explosion in each manhole. Often the most unexpected cover will blow up. Referring to Fig. 1, A, B and C represent three manhole covers connected by ducts as shown; a steel wedge was driven into a cable at P, causing a bad "earth." The manhole at B was open at the time, A and C were both caulked down and air-tight. The cover of A was light compared to that of C which was exceptionally heavy. Before A could be opened, C cover was blown up at least 20 ft., although nothing was wrong with the cables in C. After A was opened, and the fault disconnected, some gas continued burning at the mouth of the ducts, leading from B in A. It was burning with a blue flame and came in gusts, with a roaring noise, very like a large blow lamp. The faulty cable was lead covered, and paper insulated, and about 2 in. of it only were burned away. This explosion may have been caused by marsh gas, and probably the large earth current travelling on the lead of the cable produced a spark in box C. The boxes were carefully caulked down afterwards, but no trace of coal gas accumulating could be found after some weeks. It is said, however, that coal gas percolating through soil, may lose its characteristic odour. Stoneware conduits with square holes are sometimes shattered by an explosion if it takes place wholly or partly in ducts. Occasionally they will be cleanly divided as if cut with a chisel (*see* Fig. 2); this has been found to occur on 10 or more consecutive casings each 2 ft. long. As regards remedies, ventilation may be used to prevent the slow accumulation of gases, and also to minimise the effect of the explosion, but will not be an *absolute* safeguard if the gas is there and a spark occurs.

The best and easiest method of ventilation is to use ventilated box covers. Such covers must tend to promote a circulation of air along the ducts, since heavily loaded cables will heat up the air in them more than where the load is light; hence the circulation of air will be, in general, from the outskirts of a network towards the central, most heavily loaded parts. Fig. 3 is a sketch of a portion of such a ventilated water-tight

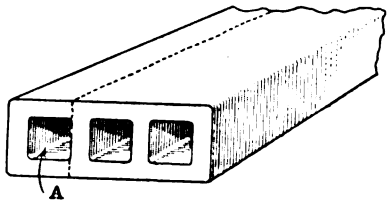

FIG. 2.—EARTHENWARE THREE-WAY DUCT.
Dotted line shows course of fracture caused by explosion in duct A.

box. The cover and frame are of cast iron, the cover being filled with concrete, and hinged, so that in the event of an explosion, the danger is very much minimised, the cover flapping open and then shutting down again. Such a cover requires no caulking; the drain pipe may be led to the gutter, or be built round with broken stones. Box covers have also been chained down to minimise the effect of an explosion; even should the chain break it is unlikely that the cover will rise high enough to *fall* on a passer-by, which is the worst danger. A brick built box, lined with cement is both cheaper and handier than a cast-iron box. There is no difficulty in making it water-tight. When it is remembered that manholes

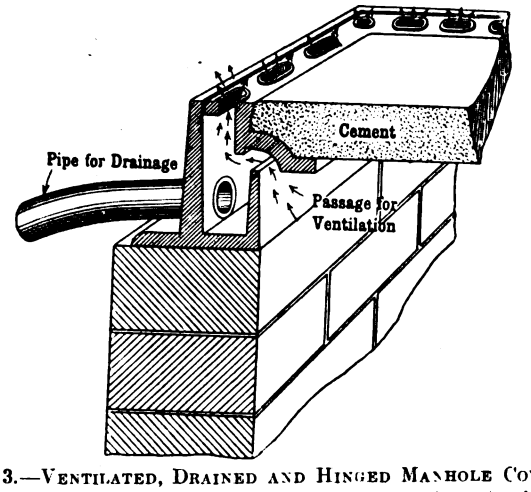

FIG. 3.—VENTILATED, DRAINED AND HINGED MANHOLE COVER.
The outlet of the drain is covered with broken stones. The cover bears at each corner. Hinges not shown.

have frequently to be built in between and amongst pipes, and with ducts coming in at all sorts of different levels, the superior adaptability of the brick box will be evident. With a cast iron manhole, it is sometimes necessary to find the place where it is possible to put it, rather than to put it in the best possible place.

Railway Electrification in Sweden.—"The Times Engineering Supplement" states that a proposal has been adopted by the Swedish Government for the electrification of the State Frontier Railway in the north of Sweden, the power to be derived from the Porjus waterfall, near Gellivare. This fall is believed to be capable of yielding 50,000 H.P.—about 16,000 H.P. in excess of the requirements when the railway is working under normal conditions. An electric generating station is to be erected at Porjus, and a railway is to be constructed from that point to Mount Gellivare. The cost of this work, including the electrification of the Frontier railway, is estimated at £1,194,500

THE SENSITIVENESS OF SYNCHRONISING APPARATUS.*

BY J. TEICHMÜLLER.

With single-phase alternators there are two methods of synchronising, viz., by so coupling them to the lamp that it either burns brightly or not at all. With three-phase machines there are still

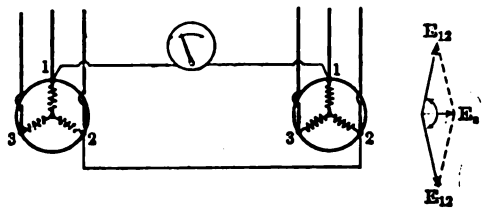

FIG. 1.—($\alpha = 180°$)

two other methods. The four systems of connections are shown in Figs. 1 to 4. The two first can be used either for single-phase or three-phase machines, the instruments being supposed to be voltmeters. Let us suppose the alternators to be in phase when the voltages in the synchronising circuits differ by the angle α, which

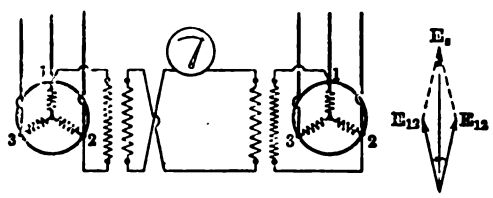

FIG. 2.—($\alpha = 0°$).

may be called the angle of synchronisation. Its value in the various cases is as follows, viz., in Fig. 1, $\alpha = 180°$, in Fig. 2, $\alpha = 0°$; in Fig. 3, $\alpha = 120°$; and in Fig. 4, $\alpha = 60°$. The vector diagrams are given in all cases, though in Figs. 1 and 2 the angle α differs slightly from its proper value, in order to show the result more clearly.

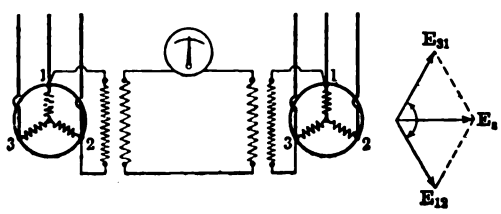

FIG. 3.—($\alpha = 120°$).

Voltage transformers are assumed in all cases to be connected to the voltmeter.

The question now arises as to which of these methods is the most sensitive, and it is necessary on many grounds to have a clear conception of the different cases, as this has a bearing not only on the method of synchronising, but also on the type of instrument to be supplied on the switchboard.

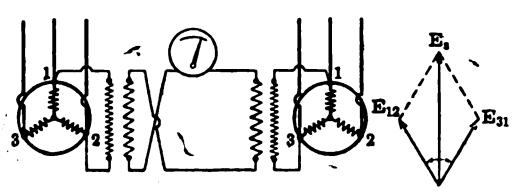

FIG. 4.—($\alpha = 60°$).

The voltmeter shows the algebraic sum of the machine voltages, each of which may be supposed to be E, the sum being E_s.

Therefore $$E_s = 2E \cos \frac{\alpha}{2}.$$

The sensitiveness of the method is given by the equation

$$\frac{dE_s}{d\alpha} = E \sin \frac{\alpha}{2},$$

the negative sign being omitted as unessential. The precise value of this last quantity is not so much the point as the extent to which it is indicated on the voltmeter. It is, therefore, necessary to consider the connection between the deflection on the voltmeter and the voltage. Let us assume that x being the deflection, the connection can be expressed as follows, viz.,

$$x = cE_s^n = 2^n \cdot c \cdot E^n \cos^n \frac{\alpha}{2}. \quad \ldots\ldots\ldots\ldots \quad (1)$$

The value of n depends on the instrument under consideration, and in order to compare the instruments on a convenient and common basis, we must suppose that the deflection in all cases is the same for the maximum voltage that can occur. This is, of course, 2E, and we have therefore $c = \frac{A}{(2E)^n}$ or $x = A \cdot \cos^n \frac{\alpha}{2}$, if A is the maximum deflection. The sensitiveness of the indication becomes

$$\frac{dx}{d\alpha} = \frac{n}{2} A \sin \frac{\alpha}{2} \cdot \left(\cos \frac{\alpha}{2}\right)^{n-1}. \quad \ldots\ldots\ldots \quad (2)$$

The expressions given in eq ations (1) and (2) are plotted in Fig. 5 for values of n between $\frac{1}{2}$ an i 6. These curves must now be examined.

The deflections have in all cases their maximum values corresponding to the zero value of α, and at this point a horizontal line through A is a tangent to all the curves. The sensitiveness at this point is in all cases a minimum. The deflections decrease with increasing values of α, falling more quickly with the higher values of n. For $\alpha = 180°$, the deflections are in all cases zero, but they approach this value in characteristically different fashion. At this point the sensitiveness is infinite for all values of n less than unity; it is zero for all values of n greater than unity; for the value 1 it has a certain finite value. Voltmeters, for which the value of n is greater than unity (and this includes probably every instrument on the market), are on strictly theoretical grounds unsuitable for the values

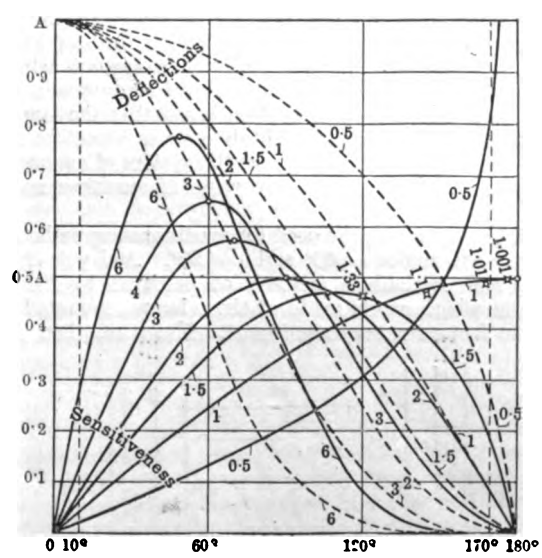

FIG. 5.—CURVES SHOWING THE CONNECTION BETWEEN THE DEFLECTION OF THE VOLTMETER AND THE SENSITIVENESS IN THE FOUR POSSIBLE METHODS OF CONNECTION.

$\alpha = 0°$ and $\alpha = 180°$. Practical difficulties would indeed be felt, if it were only ɪ ossible to switch the alternators in parallel exactly at the instan, hen there was a precise similarity of phase. But this is not so. We must find out the rates at which they tend to approach their limiting values at these points; in other words, we must study the shape of the curve of sensitiveness at these points. For the value $n = 2$, there is no difference in the choice between $\alpha = 0°$ and $\alpha = 180°$; for higher values of n the differences are most marked in the neighbourhood of $\alpha = 0°$; for lower values, $\alpha = 180°$ is to be preferred.

There are scarcely any instruments on the market for which n is equal to 1, and absolutely none for which n is less than 1. This leads us to see whether it is not possible to connect up so that there is a difference of voltage in the synchronising circuits at the instant when there is a similarity of phase in the machines themselves, in so far as their relations to the 'bus-bars are concerned. With polyphase current there are two such methods, as shown in Figs. 3 and 4. Indeed, when sensitiveness is a matter of importance, these methods are always to be preferred. For values of n greater than 2, the method in which $\alpha = 60°$ is to be preferred; for values between 1 and 2, it is preferable to connect up so that $\alpha = 60°$. It is only for $n = 1$ that it is well to consider the case of $\alpha = 180°$, but even then it is only very slightly higher than for $\alpha = 120°$. It is also necessary to bear in mind that in the cases of $\alpha = 60°$ and $\alpha = 180°$ the voltage shown on the synchronising voltmeter depends on the 'bus-bar voltage, which is liable to vary with the time of day; and it may therefore be advisable to have two scales, the one showing the 'bus-

*Abstract of an article in the "Elektrotechnische Zeitschrift," March 17, 1910.

Digitized by Google

bar voltages, to which the synchronising voltages, shown on the other, correspond.

We are now, therefore, in a position either to choose the type of instrument which suits a certain system or to choose the system best adapted for use with a given instrument. Doubtless the value of n might vary over the range of any particular instrument, but such variation would not be likely to affect the point of the argument. It might also be of interest to attempt to devise a method for use with single-phase machines by which a difference of phase in the synchronising circuits might coincide in point of time with a similarity of phase in the machines themselves; and a device of this kind, which could doubtless easily be contrived, would be of special importance in cases in which the machines were automatically connected to the bus-bars.

The curves for $n=4$ and $n=6$ are also shown, because they affect the use of lamps as indicating devices, for in the neighbourhood

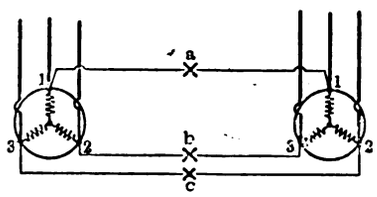

Fig. 6.—First Method of Connection on Michalke's System.

of its working voltage the illumination of the tungsten lamp varies as the 3·6th power of the voltage, and the carbon lamp as the sixth power. It, therefore, is evident that carbon lamps are more sensitive for the purpose. But it is noticeable that for $\alpha=0$ the sensitiveness is, as before, a minimum. It is therefore not astonishing that lamps give no very decided indication of an approach to similarity of phase. The objection is often heard that the lamps tend to dazzle the attendant, so that slight differences cannot be noticed, but this is probably not the case, and the system of connections is more likely to be the cause of any want of sensitiveness in the method.

Lamps obviously cannot be used for synchronising without other apparatus for the angles $\alpha=60°$ and $\alpha=120°$. And yet, if used in connection with Michalke's method, as patented by Siemens & Schuckert, in which use is made of three lamps, mounted on the board, these facts are very significant. There are then the two

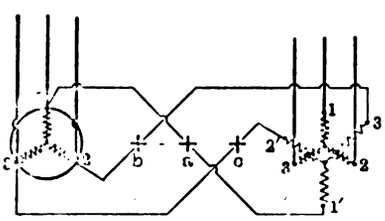

Fig. 7.—Second Method of Connection on Michalke's System.

methods, shown in Figs. 6 and 7, which are possible. The angles between the voltages are as follows, viz., in Fig. 6, for the lamp a, $\alpha=180°$; for b, $\alpha=60°$; and for c, $\alpha=60°$. In Fig. 7, for lamp a, $\alpha=0°$; for lamps b and c, $\alpha=120°$. As far as lamp a is concerned, it gives no light in Fig. 6, and shines brightly in Fig. 7. In both cases, at the moment of synchronisation, lamps b and c burn equally brightly; on either side of this point their lights are unequal. If we compare the two methods with reference to the sensibility of the lamps, Fig. 7 has the advantage in that a shines brightly, but Fig. 6 is better in so far as b and c are concerned, since we have already found that the sensitiveness is greater for $\alpha=60°$ than for $=120°$. It must, of course, be allowed that the candle-power of the lamps only varies with the 3·6th or 6th power respectively, when they are supplied with their working voltage. At 60° and 120° its value is, of course, lower, but this does not seriously affect the point of the argument.

Music by Telephone.—The "Electrical World" states that the telephone company at Wilmington have equipped a department with phonographs and keep a complete line of records. When a subscriber wants music he asks for the music operator and selects from the catalogue, supplied to all subscribers, the record he desires to hear. The result is as good as though the phonograph itself were transported to the receiving end of the line. The charges are 1½d. for regular records and 3½d. for those by operatic stars.

RECENT DEVELOPMENTS IN TELEGRAPHY AND TELEPHONY.*

BY SIR JOHN GAVEY, C.B.

We may select the ordinary Morse circuit as our starting point. With the simple form of this circuit the speed of working is limited by the skill of the operator, and rarely exceeds 30 words a minute. For many years this simple form of apparatus or its equivalents served the requirements of most countries, but as the telegraph service grew and the traffic rendered it imperative to erect long lines directly connecting distant cities, the problem of obtaining a greater revenue from the large capital expenditure involved became pressing, and progress was made broadly on three distinct lines of development. In the first, means were designed for the transmission of several messages simultaneously over the same conductor; in the second, by the use of suitable mechanical and electrical devices, the actual speed of transmission was raised in overhead wires to 10 or 12 times that possible by manual operating, and, finally, type printing and writing systems were invented with varying degrees of success.

Simultaneous Transmission.—In the duplex system, which admits of the simultaneous transmission of two messages in opposite directions over the same wire, at each end of the circuit is a differential receiver which comprises two equally-balanced electromagnetic coils, one of which is connected at its further end to the line wire and the other to an artificial line, which, in its electrical resistance and capacity, is as nearly as possible the equivalent of the actual line. The two inner ends of the magnet coils are connected together, so that when a current is sent from the point of junction it divides equally between the actual and the artificial lines, and the magnetic effect of one coil being neutralised by the magnetic effect of the other, the signals originating at either end pass through the home apparatus without affecting it. At the far end, however, the current passes through one coil alone of the receiving apparatus and the signal is recorded. When both keys are depressed simultaneously, if the batteries are so connected that they aid each other, then the current which circulates through the line wire and through both of the magnet coils connected thereto is doubled; but as the current which circulates through the magnet coils at each station connected to the respective artificial lines is unaltered a signal is recorded, because the balance at either end is destroyed by the action of the other operator.

The transition from duplex to quadruplex working—viz., the sending of four messages simultaneously over one wire—involved but a step. A single-current key is connected to a powerful battery which is intended to work a non-polarised magnet, but the connections are led through a reversing key, which latter is designed to actuate a polarised magnet. When the single-current key is depressed the powerful current that circulates through the apparatus actuates the non-polarised relay at the far end, leaving the polarised relay unmoved. When the reversing key alone is depressed, a weak current circulates which actuates the polarised magnet, but is too weak to act on the non-polarised instrument. If both are depressed simultaneously the powerful current from the single-current key is reversed by the depression of the double-current key, and both instruments at the far end are affected. The receiving apparatus at each end is arranged differentially, as in the duplex system, so that the outgoing currents have no effect on either of the receivers at the home end. This arrangement admits of four operators sending four messages simultaneously over one wire.

Another method, based on entirely different principles, which in theory admits of sending as many as 12 simultaneous messages in one direction, or double that number if duplexed, depends on the superposition of musical vibrations on a telegraphic circuit at one end of a line. To effect this result a number of electrically-driven tuning forks, arranged to vibrate at different frequencies, are connected through telegraphic keys to a line wire, so that on depressing any one key a series of electrical vibrations, of the frequency of its companion tuning fork are sent through the line. At the far end the receivers are of a type that will respond to musical vibrations only, and each receiver is constructed or adjusted to respond to the vibrations of one of the distant tuning forks alone and to no others. This system originated in America, but it has been developed and improved by Mercardier, in France, where it is said to have given good results recently. In the modern apparatus the receivers consist of so-called mono-telephones, each of which is so made and adjusted as to respond to only one frequency.

A method of multiplex telegraphy, based on entirely different principles, is the following: A large number of insulated metallic segments are arranged in a circle at each end of the line and divided

* Abstract of the "James Forrest" Lecture, delivered on Wednesday evening before the Institution of Civil Engineers

Digitized by Google

into groups, say, of eight each. No. 1 of the first group is metallically connected with No. 1 of all the other groups, and, through the transmitting key, with No. 1 instrument, No. 2 with No. 2 series of contacts and instruments, and so on. Centrally-pivoted arms, provided with metallic brushes which ride over the segments, are joined one to each extremity of the line wire, and it is obvious that if both these arms, starting simultaneously from No. 1, revolve at precisely the same speed, then each segment with its instrument at one end is for a brief period placed in connection with its corresponding segment of the instrument at the distant end. If the sending key of No. 1 instrument is depressed, a brief current is transmitted to its corresponding instrument when the revolving arm reaches No. 1 contact of any group, to be repeated when the arm reaches No. 1 of the next group, and so on throughout the series. Instead, therefore, of a dot being represented by a single current of continuous duration, it is replaced by three or four shorter impulses spread over the same period of time, and a dash by three times the number of impulses. By this means it is possible, under favourable conditions, to transmit eight messages simultaneously over one wire. This system, invented by Delaney, was developed to some extent in this country, but owing to various causes it has recently been abandoned. It is, however, referred to here as the principle of revolving commutators is in use in other forms of apparatus to be dealt with later. The second method of increasing the output of telegraphic wires is the automatic or machine-transmitting instrument, which is typified by the Wheatstone apparatus adopted and perfected by the Post Office in Great Britain. In all instruments of this character a long paper ribbon is perforated by a suitable machine in an arbitrary manner, and the transmitting and receiving apparatus is so designed as to transcribe these perforations at the distant end into Morse signals, into similar perforations, into type printed messages, or even into written characters.

There are three rows of perforations in the tape, or slip, of the Wheatstone system. The centre row is continuous, as it is used for drawing the slip through the transmitter at the speed at which the latter is running, the upper and lower holes cause the transmitting key to send electrical signals, dots when these rows are vertical, dashes when diagonal. The actual apparatus which effects this object is comparatively simple. Two small vertical plungers, to which an up-and-down motion is imparted by the clockwork of the apparatus, are pivoted to two bent levers connected by horizontal rods with a small vertical transmitting key, which in one position sends a positive and in the other a negative current to line. When no slip is in the machine, the plungers as they rise and fall move the key to and fro and send reversals, which are received as dots at the far end. When the slip is inserted, if the plungers meet a series of vertical perforations they pass through at each movement and dots are still transmitted, but if they meet diagonal perforations the movements of the plungers are arrested by the unperforated portion of the paper slip, and the transmitting key is not drawn back until one of the plungers enters the lower diagonal hole of the slip, and withdraws the key from its sending position, thus recording a dash.

This Wheatstone system has been very fully developed in the United Kingdom. It is capable of dealing with traffic at a maximum rate of 450 words per minute, and it is invaluable for the transmission of news. Thus, in the central office in London, items of news may have to be transmitted to 50 or more towns simultaneously. Circuits are made up for news transmission, each providing for a number of towns, some of the circuits being of a permanent character and some formed temporarily to meet special requirements. As many as eight Wheatstone slips can be punched simultaneously in one operation, and each length of slip is run through the necessary transmitters at the highest speed considered judicious.

For ordinary public message traffic, on lines of moderate length, where each individual message is short, the Wheatstone has certain disadvantages—namely, the initial delay in perforating the slip, its distribution, and finally the re-distribution of the received slip amongst the writing telegarphists; for it is obvious that at the high speed at which Wheatstone is worked several operators are required at each end of the line to keep pace with the apparatus. In practice in this country, for circuits of moderate length, it is generally considered preferable to provide direct Morse apparatus worked simplex, duplex or quadruplex as circumstances may dictate.

With overhead lines the limit of speed in automatic working is that imposed by the receiving apparatus, which, owing to its self-induction, obstructs the reception of Morse signals at a higher speed than that named. This difficulty has been overcome by substituting a chemical for an electromagnet receiver. In this form the current at the received end passes through a long paper ribbon saturated with a solution which is decomposed by a positive current. The Morse signals appear in blue lines on the received slip. It is said that with this method a maximum speed of 1,000 to 1,200 words is possible under favourable conditions, but the difficulty in working at such high speeds, where characters are received in Morse code, and have to be transcribed manually, is the division and distribution of the slips amongst the large number of writers necessary to keep abreast of the work, the precautions needed to avoid loss of messages, the injurious effect of brief contacts caused by workmen which result in the loss of several words, and last, but not least, the difficulty and delay in obtaining repetitions where errors, false signals or missing words render this necessary.

All the foregoing methods increase the carrying capacity of the wires; in other words, they reduce the capital expenditure per message, but none of these increase the output per operator, nor do they diminish the working cost in the instrument room; in fact, with high-speed automatic transmission this cost may be higher than with other methods described. The initial preparation of the transmitting slip will always, of course, be necessary in all automatic systems; but inventors have turned their attention to increasing the speed and reducing the cost of transcription at the received end, in the case of manual as well as automatic sending, by the substitution of typing apparatus worked mechanically or electrically for the manual transcription. One of the earliest of such instruments, which has met with permanent success, and by means of which a very large proportion of the work in Europe, and nearly the whole of the trans-Continental work, is dealt with, is the well-known Hughes type-printing instrument. This consists of a disc, on the periphery of which are embossed the letters of the alphabet, numbers and other signals that have to be transmitted; a piano-like keyboard and a horizontal plate with a series of slots arranged in a circle. Enclosed in each of these slots, and connected with one of the sending keys, is a movable plunger, which is raised when the key is depressed, but which normally lies flush with the surface of the plate. An arm carried on a vertical shaft in the centre of the plate is caused to revolve above it by the motive power which drives the instrument, and when a key is depressed this arm is arrested momentarily by the protruding plunger, and a current is sent to the distant station. The printing disc and the revolving arms at both sending and receiving stations move in unison, this being effected mainly by the action of a governor, any slight want of coincidence being corrected mechanically each time a letter is printed.

The Hughes method of transmission has many advantages. It provides a clearly-typed message for delivery instead of a written one, it removes a possible source of error in transcription, and it increases the speed of working as compared with Morse by about 25 per cent. It can be duplexed, and it is used by the Post Office on all its Continental wires. It has, however, the disadvantage that a considerable interval of time elapses between the transmission of two consecutive signals, owing to the revolving arm having to traverse all the intervening letters. Baudot has obviated this waste of time by adopting the multiple system of telegraphy. He entirely abandons the Hughes method of transmission, and forms an arbitrary signal code, in which, by means of five consecutive currents, some plus some minus, in combination, he represents each letter of the alphabet, figures or other signals. By his method he can provide four or six channels simultaneously on one wire, each being worked manually. The translation of these arbitrary code signals into printed letters is effected in the following very ingenious manner: At each receiving instrument two discs, firmly fastened together, have on their peripheries a series of serrations, corresponding with the arbitrary code, which, in certain defined positions, represent the various letters of the alphabet. Riding on the periphery of one of them are five levers termed selectors, each of these levers being so pivoted as to be susceptible of a slight to-and-fro movement on its axle, and also of a transverse movement in the line of the axle. When all the electromagnets have their armatures raised the selectors rest on the inner disc, but if a certain number of the armatures are depressed, then, through the action of intermediate levers, the corresponding selectors are shifted to the second disc. As the two discs revolve together the combined selectors at some point drop simultaneously, and for a brief interval, into the series of serrations which correspond with the letter code signalled from the far end, and this movement and the rapid jerk out of the serrations as the discs revolve cause the letter to be printed from a type wheel which revolves at the same speed as the discs. The uniform revolution of the contact arms, the coded discs and the type wheels is maintained by a clever adaptation of governors and brakes, partly electrical, partly mechanical. The Baudot system admits of the transmission of a much larger number of messages over each wire than the Hughes. It is also more flexible, inasmuch as the various channels it provides can be divided amongst an equal number of towns. It is largely used in France and has been introduced into this country.

Digitized by Google

Murray has devised a system which has undergone lengthy trials both at home and abroad. His slip has one row of perforations which gears into the moving mechanism of the transmitter, and below this a second series of perforations which represent his artificial signalling code, which is of the Baudot type. The transmitting and receiving apparatus are arranged to run synchronously. When the vertical plunger of the transmitter passes through a perforation a positive current is sent over the circuit, and when the plunger is stopped by the paper a negative current circulates. The result at the receiving apparatus is that an exact counterpart of the transmitted slip with its perforations is reproduced, and this perforated slip is passed through and actuates an automatic typewriter which prints the message. The typing machine is fitted with five horizontal plungers, which are prolongations of an equal number of slotted combs, to which in action a to-and-fro motion is imparted. The perforated slip acts on the principle of the Jacquard loom, and when at a given moment a series of perforations appear the corresponding plungers move forward and the remainder are arrested by the unperforated part of the paper. The slotted combs are at the moment so grouped that the one letter indicated by the code is actuated by the controlling motive power, and it is accordingly printed, and the combs restored to their normal position ready for the next letter. The message is typed in page form.

Creed has worked in the same direction, but he uses the ordinary Wheatstone alphabet and Wheatstone transmitter. At the receiving end a perforated Wheatstone slip is reproduced by a punching machine, which, controlled by the reverse currents from the transmitter, and, using compressed air as a motive power, perforates the received slip at considerable speed. This slip is then passed through an automatic typewriter adapted to work with the Wheatstone alphabet, which types the message on a long slip, to be gummed on the telegraph form. In both these cases the received slip can be inserted in a second automatic transmitter and the message sent on to another town—an advantage in the transmission of news. Both these systems are in use in the British Post Office.

(To be concluded.)

FIFTEENTH ANNUAL CONVENTION OF THE INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION.

(Concluded from page 405.)

The annual dinner of the Association was held on Thursday, June 16th, at the Windsor Hotel, with Mr. W. W. Lackie, the retiring President, in the chair. The proceedings were of more than usual interest, and the function was very well attended. The speeches were of the usual complimentary order, and the praises of the Association were duly sung by the conveners of the electricity committees of Glasgow and Govan. Mr. John Christie (Brighton) proposed the toast of the City of Glasgow and referred to the contemplated extension of the electricity undertaking by the erection of a monster power house on the banks of the Clyde. Sir John Ure Primrose made the speech of the evening, and was particularly happy in his reminiscences of the early days of the electrical industry. He reminded present-time central station men, and particularly those in charge of great undertakings like Glasgow, of their indebtedness to Mr. Ferranti for his pioneer work at Deptford. These remarks aroused great applause for the new I.E.E. President, who, through some evident official oversight, was seated among the guests below the top table. In response to subsequent persistent calls for a speech, Mr. Ferranti acknowledged the ovation, with his usual modesty, by expressing his thanks in a few simple words.

The proceedings of the 1910 Convention were brought to a close on Friday by the business meeting which was held in the Rankine Hall of the Institute of Engineers and Shipbuilders. There was a good attendance, and the election of President, Officers and new Members of Council was at once proceeded with.

The following is a full list :—

President : J. Christie (Brighton).
Vice-Presidents : G. Wilkinson (Harrogate), C. E. C. Shawfield (Wolverhampton).
Past-Presidents : H. Talbot (Nottingham), S. L. Pearce (Manchester), W. W. Lackie (Glasgow).
Council : A. C. Cramb (Croydon), J. H. Rider (L.C.C.), C. Furness (Blackpool), R. A. Chattock (Birmingham), F. M. Long (Norwich), T. P. Wilmshurst (Derby), A. H. Seabrook (Marylebone), S. J. Watson (Bury), Alderman Sinclair (Swansea), Alderman J. P. Smith (Barrow-in-Furness), Alderman Bruce (Sunderland), Alderman West (Coventry), Bailie Willock (Glasgow), Councillor German (Brighton).
Hon. Solicitor : Alderman G. Pearson (Bristol).
Hon. Treasurer : J. E. Edgcome (Kingston-upon-Thames).
Hon. Secretary : H. Faraday Proctor (Bristol).
Secretary : C. McArthur Butler.

Mr. Lackie announced that the Council had also elected Mr. C. H. Wordingham to be an honorary member.

The fifteenth annual report of the Council was then read, and is given below in abstract.

ANNUAL REPORT OF THE COUNCIL.

The membership of the Association now stands at 416, made up as follows: Committees (members), 170; chief electrical engineers (members), 191; honorary members, 3; chief assistants (associate members), 11; assistants (associates), 41. After allowing for deaths, resignations, removals and lapses due to members leaving municipal employ, there is an increase of 26 on last year's total.

The revenue account shows decreased expenditure under nearly every heading and an increased revenue. The Convention receipts balanced the outgoings. The net result is a surplus for the year of £93. 10s. 1d., or more than double that of last year. The balance-sheet shows a margin of assets over liabilities of £485.

Standard Specifications.—The Sub-committee on Physical Standards of the Engineering Standards Committee, upon which the Association is represented, have in hand at the present moment a standard specification for bayonet socket electric lamp-holders. This specification is already printed in draft, and its issue may be expected in due course. The Sub-committee also engaged, in co-operation with the manufacturers, in preparing a specification for metal filament lamps. The completion and issue of this specification is, however, likely to occupy some considerable time.

Charges for Current Supplied for Traction Purposes from Combined Undertakings.—The Council have been approached by the Municipal Tramways Association with a view to a joint committee being formed to discuss the question of standardising the method of charging for current supplied for traction purposes from combined undertakings. A committee of the Council subsequently met a committee of the Municipal Tramways Association, and at this conference a small sub-committee was appointed, consisting of Messrs. McElroy and Spencer, representing the Municipal Tramways Association, and Messrs. S. L. Pearce and T. Roles representing the I.M.E.A. A proposal has been drawn up by the I.M.E.A. representatives, outlining a suggested method of arriving at a correct traction charge, and will be considered in due course by the tramway representatives.

Electric Lighting Act, 1909.—The vexed question of a clause enabling local authorities generally to provide electrical fittings, &c., was unfortunately thrown out of the bill, although great efforts were made to get this clause retained. Considerable criticism was offered by the technical Press as to the action of the Association in permitting its views to be made public in connection with this matter. To avoid doing so would, however, have necessitated excluding these very critics—namely, the technical Press—from the Association meeting, which would, of course, have been most unfortunate, and even had that been done the Association views would have been explained in detail to so many members of Parliament that they must have, sooner or later, become more or less public property.

A clause has been inserted in the Act protecting authorised undertakers from encroachment by unauthorised undertakers. This clause does not, however, go quite as far as was desired, although it is of considerable assistance.

Income Tax and Depreciation.—The Council have given very careful consideration to this question, but at present are unable to make any definite recommendations. It is felt generally that there is far too wide a divergence between the lives of assets, as allowed by the two Government departments—viz., the Inland Revenue department for the purposes of assessment, and the Local Government Board for the purposes of loan periods. As indicated in the circular letter addressed to the members on March 4th, one of the largest cities in the kingdom was about to be penalised under the question of assessment of its mains. Immediately the attention of the Inland Revenue authorities was drawn to this letter, however, the question was re-opened and the allowance will probably be made. Of about 76 returns received, it is found that there are 18 undertakings where the income tax, although payable, has not yet been paid, and eight of these undertakings are resisting the terms offered by the Inland Revenue department.

Economic Wiring.—A sub-committee have been in negotiation with a sub-committee of the Cable Makers' Association, and a

Digitized by Google

specification for a class of conductor which it is considered would satisfactorily meet the requirements of the fire insurance authorities has been drawn up. This should enable installations of this class to be carried out in an efficient manner at a minimum of cost.

Travelling Studentship.—The Council again expresses its regret at the lack of interest shown by the associates in regard to the scholarship of £10 offered annually for the best Paper on some approved subject. This year again no entries were received, and the award has only been made twice in four years.

The discussion on the report was mainly confined to the subject of municipal wiring powers. Mr. Mark Ruddle (Dublin) asked that a special effort should be made to extend the power of supplying fittings, wires, &c., to all the municipal undertakings connected with the Association. A concerted effort on the part of those municipalities which enjoyed such powers with those undertakings which did not yet possess them would doubtless bring about the desired result. Mr. F. W. Purse (Watford) seconded this proposal, and Mr. A. C. Cramb (Croydon) spoke in support of it. Mr. Cramb referred to the difficulty of working amicably with contractors, and stated that one of their principal grievances was the question of the discount on goods sold by the electricity department. Alderman Pearson (Bristol) commented upon the exclusion of the wiring clause from the Electric Lighting Bill of 1909, and said that had they allowed the clause to stand their position would have been worse than before. He was of the opinion that even if a special Bill were promoted by those municipalities at present without powers, such a Bill could not be got through the House of Lords at the present time. Mr. J. E. Edgcome (Kingston-on-Thames) remarked that the Association of itself had no powers to promote a Bill, but that if the necessary funds were forthcoming from the interested municipalities, the Association would then be able to proceed. Responding to a request from Mr. A. Blackman (Sunderland) as to the cost of the Bill, Alderman Pearson replied that it was largely a matter of the opposition encountered. The House of Commons procedure might cost very little, but if the Electrical Contractors' Association fought them, both in the Commons and in the Lords, the cost might run into upwards of £500. Mr. T. D. Clothier (Bootle) thought that the Bootle Corporation would withdraw its support from the Association if a strong action was taken in this matter. They were keenly opposed to the extention of municipal trading along these lines. Mr. W. G. Pickvance (Wrexham) expressed surprise at this suggestion. His experience at Wrexham was that it was next to impossible to co-operate with contractors, and on this account he had kept his wiring department going. The discussion concluded by a resolution that subscriptions be invited from all municipalities, whether members of the Association or not, towards a fund in support of a Bill which would extend wiring powers to all municipalities.

A further discussion then took place on the subject of a satisfactory information bureau, but as there appeared to be a conflict of opinion amongst the participants, Mr. Lackie stated that the matter would receive the careful attention of the Council.

Replying to a suggestion made by Mr. W. G. Pickvance that the Council be enlarged so as to include representatives of the smallest stations, Mr. Lackie said that a special meeting of the Association could be called to discuss the matter if Mr. Pickvance could secure the co-operation of ten other members. Mr. C. Turnbull asked that the Council would appoint special committees to consider certain problems, which were of the utmost interest to certain of the members. He cited as a typical subject the supply of electric power by municipalities to tramway companies. Mr. F. W. Purse (Watford) complained of a difficulty in giving a supply outside his area, such as was sanctioned under the Electric Lighting Act, 1909. Before approaching the Board of Trade on the matter of laying mains, the permission of the County Council, who are usually the road authority, had to be obtained. The Hertfordshire County Council had required a deposit of £100 from him before he could obtain this permission. Alderman Pearson pointed out that a licence by letter for supply outside a borough could be obtained under the Act of 1909, and that if the County Authority was inclined to be unreasonable, their consent could be dispensed with by the Board of Trade. On the suggestion of Mr. A. C. Cramb, that two members be deputed to represent the Association on the Joint Publicity Committee, Mr. J. Christie (Brighton) and Mr. F. Ayton (Ipswich) were appointed. Mr. Lackie said that the Council was endeavouring to legalise the Wiring Clause, the Standby Clause and the question of delegates' expenses in connection with the Convention.

The proceedings were brought to a close by the passing of a hearty vote of thanks to Mr. W. W. Lackie and the Corporations of Glasgow and Edinburgh for their hospitality to the members of the Association during their visits to the respective cities.

On Friday afternoon many of the engineers and their wives took advantage of the fine weather to enjoy a steamer trip down the Clyde to Rothesay, and round the Kyles of Bute.

Erratum.—We regret that in our last issue Mr. F. E. Ayton was not quite correctly reported in regard to cement for settings and flues. The cement recommended is made of ground firebrick mixed with Portland cement.

CORRESPONDENCE.

FISCAL POLICY AND THE ELECTRICAL INDUSTRY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to Mr. Hookham's letter in your last week's issue, I should like to give a few points showing that our free imports of manufactured goods and food were not in any way the cause of our national prosperity in the years up to 1880.

There are many points requiring explanation, by reason of the political cry, as to the advantages of free imports. Landowners had considerable political power in those days, and the desire of many residents in towns was to minimise their influence, and this Free Trade cry was so continually used that it was accepted as an article of faith by many, and the whole nation was prospering so greatly—including the landlords—that no one took the trouble to repudiate it.

The cause of our national prosperity was our civil and mechanical engineering development, assisted by other features, such as the discovery of gold in California, U.S.A., in 1847 and in Australia in 1851, which much increased the world's trade.

People constantly refer to the "hungry forties" as an argument against Protection. During this period there was a great deal of disorganisation throughout the kingdom owing to the great development of new cotton, woollen and other machinery, and consequent upon this development a young girl could do the work which formerly required two or three men. The Chartist riots and the burning of machinery was provoked by loss of work and wages, many men going back to the land; but by 1850 these riots had passed away and great development in mechanical machinery, combined with cheap coal found in the neighbourhood, enabled us entirely to control the world's supply of these manufactured goods. No country in the world had any mechanical knowledge or suitable coal, and even with wages at 4s. a month, workers could not compete against us. The railway development in foreign countries also enabled us to send these goods inland and increase our cotton and woollen manufactured exports in those places where it was very difficult to deliver articles of commerce.

Free Traders argue that distress during this period was due to high prices, although the proofs are clear that a temporary check on employment was caused by these inventions in machinery, which a few years later developed in a marvellous manner our trade with the world and greatly helped to start our national prosperity. A glance at "Whitaker's Almanac" for some years back will convince any observer that there was very little difference in the price of corn before and after Free Trade, and meat, vegetables and eggs, &c., were far cheaper than they are now. People do not recognise the difficulties of conveying goods and foodstuffs in those early days prior to

Digitized by Google

1846. People born in 1860 or 1865 would now be 50 or 45 years old; the earliest age at which they would begin to consider any question would be 18 years—in 1878 or 1883—and none of them can realise the difficulty which traders and others had to contend with in importing foodstuffs and bulky produce from abroad.

Here are some of the difficulties :—

1. *Navigation.*—Sailing ships of small tonnage only (about 500 tons), hardly any docks available, bad harbours and rivers dangerous, bad navigation charts and instruments, few and bad lighthouses, many more wrecks in proportion owing to sailing only, long voyages, high insurance charges, long periods of waiting for cargo in the different ports (sometimes months, when the interest on the unemployed ship's capital was lost), all tended to make the cost of imported corn and goods almost prohibitive.

2. *Inland Communication.*—In the early part of the period referred to, railway carriage of goods was unknown. Prior to 1846, when railway construction commenced, we being the pioneers of this important movement, travelling by road was very difficult. One ton of stuff carried 100 miles cost £3. Rivers and canals, confined to certain parts, were the easiest means of conveyance; but in 1845 and 1846, 272 Acts for the construction of railways were passed in this country.

3. *Various Difficulties.*—In the days referred to we had no telegraph, telephone, electricity or cheap postage, newspapers scarce and difficult to be got, consequently no reliable commercial intelligence. To compare the period before the Corn Law repeal with the enormous advantages we now possess is unreasonable.

On p. 442 of "Whitaker's Almanac" for 1905, readers will see that the average price of corn was but little lower for 16 years after the repeal of the Corn Laws came into operation, in January, 1849, than for the 16 years before, clearly showing that the cost of transport had more to do with the question than anything else. Our own improvements in agriculture, such as drainage, guano and other manures, and machinery, all helped to reduce cost and increase quantities, and agricultural land from 1850 to 1880 almost doubled in value. Almost every inch was cultivated, and much employment found, owing to the fact that the expense of carrying corn to this country from Chicago was 60s. per ton more in 1860 than it now is, our agriculturists having higher protection on corn in those days than any foreign country at the present day with a duty; so that railways abroad and steamships, invented and made by ourselves, have practically, under "Free Trade," destroyed our own agricultural industry.

In Meyer's "Encyclopædia," published in Germany in 1849, there appears an article on Great Britain. [We regret that pressure on our space does not permit us to reproduce the extract sent by our correspondent, which states that Great Britain outshines all other countries in every branch of human activity, that agriculture and cattle raising are extraordinarily prosperous, that England and Scotland are the workshops of the world and swamp the whole earth with produce, that the position of Great Britain makes a large export to foreign countries absolutely necessary, and that rapid decay would result if foreign markets were closed against her.] This clear explanation from Germany is correct on every point, and ought to convince readers as to the cause of our national prosperity.

The special advantage of our national prosperity was unquestionably due to the coal and iron lying near the sea, causing it to be shipped abroad at the cheapest rates, preventing all foreign competition, owing to its low price. Also, having the world's markets in our hands assisted mechanical and civil engineering development at home as soon as railways and steamship building commenced. For 30 years we made railways, steamships, engines and machinery for every country in the world, and charged our own prices. As an illustration of how mechanical work came naturally to this country: America up to the sixties had developed a good building trade in wooden sailing ships. Having large quantities of suitable wood available adjoining their lakes and rivers, they could build at very reasonable prices, but upon the development of iron-built steam ships the business came naturally to this country and continued here for some years. The railway development in foreign countries assisted greatly the increased export of cotton and woollen manufactures all over the world. With corn but little cheaper for 16 years after the repeal of the Corn Laws than for the 16 years previous to that repeal, how can it be argued that our prosperity was due to so-called Free Trade? When we first allowed free manufactured imports, two of our workers' industries were promptly almost destroyed—the silk trade and the watch trade. And why? A ton of these valuable goods sent over cost but little more for transport than a ton of corn. If it cost £3 a ton it would amount to a trifle when divided over the watches and silk, but it would represent 12s. per quarter extra cost on the corn. The loss of these two industries was not at that time severely felt, except in certain towns, for we were so busy manufacturing machinery, &c., for the whole world that we did not feel the loss. People did not find much difficulty in obtaining employment in other directions in those days, as many markets were open to us on payment of comparatively small import duties.

Free Traders now argue that, because during 1850 and 1880 many people transferred their labour to other works and trades, they can do so now, when the foreigners, whose countries have been opened up with railways, coal and iron mines and means of quick transport, are flooding our markets with their manufactured goods and trying to supply our colonies also, and taking nothing from us on equal terms. Free Traders say tariffs on foreign-made goods benefit the few at the expense of the many, whereas it is contrary to fact. Workers are by far the larger number of our population, and how can the worker benefit by the importation of electrical machinery, motor cars, watches, silks, pianos, jewellery, &c.? Manufactured imports amounted in 1908 to 120 millions sterling net after deducting re-exports (*see* "Whitaker's Almanac" for 1910, p. 471).

A British electrician who can start a factory abroad has special advantages. He has a connection on the home market, say 10,000 customers, supplied at home free of duty, and he may work up another 10,000 foreign customers where he establishes his business. We know that 20,000 people can be supplied at a cheaper rate than 10,000 people; so that he is really better off by moving abroad, as he cannot supply the foreign 10,000 customers from home, except at prohibitive prices, owing to the duty put on by foreigners.

Now, suppose these goods are delivered rather cheaper than they can be made at home. After a few years the home trade dies out. The foreigner will then command the market and raise his price. Ultimately we shall be worse off than before, besides losing employment for a large number of people.

As regards the electrical trade, it was undoubtedly severely handicapped by the Legislature in its early days, electricians having no home market to supply for several years. There seems, moreover, little doubt that countries able to use water power for electrical and other manufactures will be able to compete against coal, provided the water storage can be effected at small cost and lower wages taken than in this country.

In concluding these notes, I should like to quote the opinion of the late President McKinley, (U.S.A.): "The people of no nation in history has ever permanently prospered under a policy which sacrificed its home industries to build up and develop the resources and give employment to the labour of foreign states."

The enormous emigration of our working men as compared with Germany shows clearly that we are giving our workmen's wages to the foreigner, in order that we may obtain cheap goods.—I am, &c.,

Ealing, June 21. BENNETT FITCH.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of June 17th you publish a letter on the above subject from Mr. George Hookham. I differ wholly from his conclusions, but I cannot fail to admire the clear and definite way in which he states his case. Particularly do I

Digitized by Google

appreciate his nut-shell paragraph in which he proves that Protection may diminish employment. I am a Tariff Reformer because I believe that there is at present a terrible quantity of unemployment in this country, and because it seems to me that protective duties cannot fail to act as a remedial measure. I do not claim that they would necessarily effect a complete cure.

In the above-mentioned nut-shell paragraph Mr. Hookham's arguments are these :—

1. Protection, if it protects, raises prices.
2. Purchasing power is therefore reduced.
3. Demand and production fall off.
4. Down goes employment. (Q.E.D.)

Mr. Hookham has overlooked a few important modifying agencies, but we will not stop to press that point. His little syllogism may work out just as he says, *but* he omits to state where the employment goes down. If we can gain employment for a thousand Britishers by putting twelve hundred Patagonians (or others) out of work, then I fear it is our duty to push aside our altruistic instincts and help our own country in the great international struggle.

An effective 5 per cent. duty cannot raise the price of the goods as much as 5 per cent., so the consumption can hardly fall below 96 per cent. of its Free Trade value. If, however, it has the effect that instead of importing half of what we need we make three-quarters ourselves the net result is this :—

Under Free Trade 50 British-made articles.
Under Protection 72 British-made articles.

To my limited understanding that looks like a gain to the country, in spite of the total reduction of output.

It is always a little risky to dogmatise about the motives and mental processes of one's neighbours. The picture drawn by Mr. Hookham of the "stubborn fervour" of the Tariff Reformer bears a marvellous resemblance to my secret idea of the Free Trader. We are all in need of Burns' "giftie." I would fain say more, but that business reasons forbid my writing over my own name, and compel me reluctantly to sign myself

London, June 20 MUDRETZ.

ELECTRIC STEERING GEAR FOR SHIPS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In my article on the above subject, which appeared in your Marine issue, I omitted to mention my indebtedness to the Siemens-Schuckert Co., of Berlin, who were kind enough to send me some information regarding the progress which is being made on the Continent in this direction. This Company are interesting themselves more, perhaps, than any other firm in Germany, and anticipate important developments in the near future.—I am, &c.,

London, E.C., June 20. A. P. CHALKLEY.

ISLES THIMBLE WORKS.

From the remotest antiquity some form of protection has been used for the fingers when sewing. In the earliest times fish bones were used as needles, and a leather shield was all that was required to protect the finger, but the introduction of bronze and steel needles made a metallic protection necessary. Curious bell-shaped contrivances used for the purpose have been found in the tombs of the Egyptians and the excavations at Pompeii.

The modern thimble is the result of many centuries of development, and in the Isles Thimble Works, Birmingham, thousands of these indispensable little articles, made of nickel silver, steel, aluminium and celluloid are turned out weekly. This old-established firm, like others, has felt the effects of foreign competition, and recently was forced by the keenness of this competition to realise the possibilities of the electric drive. The firm decided to throw out the gas engine plant, and to equip electrically the whole of their works. The contract was placed in the hands of the British Westinghouse Electric & Mfg. Co., with the happiest results, as not only have the power costs been considerably reduced, but the great convenience of the electric drive has been fully realised.

It is quite interesting to follow the thimble through the varous stages of manufacture. The different metals used for making the various thimbles are taken from the warehouse to the punching department, where blanks are cut out from the thin sheets of metal. These blanks are then taken to the machine shop, where they are formed roughly into shape by passing them through two sets of dies. This shop is driven by a 7 H.P. Westinghouse shunt-wound motor, running at 830 revs. per min., which operates the lathes, presses, and small grating machines from a shafting running the whole length of the building.

The rough thimbles are next taken to the raising department, where they are put into hand-operated presses and given the correct shape; and from there to the finishing departments, of which there are two. One, which is operated by a 4 H.P. Westinghouse shunt-wound motor, is used for finishing off steel thimbles, and the other, operated by a similar motor, for those made of aluminium. In this department, the thimbles are grated, machined inside and on the edges, and then sent to the annealing department. The next operation is carried out in the dipping shop, where they are cleaned in an acid solution, and then, should they require silvering, they are passed to the silvering vat; before being put into which, however, they are dried in a rotating barrel, containing sawdust. From here they pass to the polishing room, which is operated by a 1½ H.P. Westinghouse motor, and to the inspection and store rooms.

The manufacture of celluloid thimbles is a distinct branch of the business, and is carried out in a separate building. These thimbles are made from solid celluloid rods of about ½ in. diameter, which are first cut into lengths of about ⅞ in., and then heated with hot water for a few minutes, being afterwards taken and moulded into shape and size in a small press.

These rough thimbles are then put into the drying chamber, for from 10 to 15 days, and when they are sufficiently hard, taken to the finishing department where they are machined inside and finished in small lathes. In this department, celluloid finger shields are also made in thousands every week. The power necessary for operating this department is small, and a 3 H.P. Westinghouse motor is ample for the work.

The firm manufacture a number of thimbles lined with celluloid, and their most recent patent is for ventilated thimbles, for which many inventions have been tried, but which they now claim to have solved in a practical manner. They do not confine themselves only to the manufacture of thimbles, but also make fancy boxes for enclosing them, and cardboard boxes. The guillotine marking and cornering machines are driven from a shafting running the length of the building and operated by a 5 H.P. Westinghouse motor placed on the floor.

L.C.C. TRAMWAY ESTIMATES.

On Tuesday the Highways committee submitted a summary of the estimated results of the working of the tramways for 1910-11.

The surplus on the electric lines was estimated at £934,180, and the deficiency on the horse lines £22,170, giving a net surplus of £912,010, making, with £27,233 for interest, rents, &c., £939,243. The debt charges are £662,266, income tax and sundry items £32,845, giving a net surplus of £244,132, of which £125,989 will be devoted to renewals fund and £118,143 placed to general reserve.

The committee state that the results for 1909-10 are such as to enable the full amount for renewals to be transferred in respect of that year, and also an amount to cover all shortage in the fund under the basis of provision for renewals settled by the Council on June 23, 1908. The estimates submitted are dependent upon certain dates being observed in regard to the opening of further electric lines, the progress of which is somewhat uncertain. The total expenditure on capital account for tramways up to March 31 amounted to £10,710,000, and it is estimated that £2,800,000 further will be required to complete the work of electrification and the construction of authorised lines, making a total capital outlay of about £13,500,000. The amount of £2,800,000 includes £850,000 in respect of the reconstruction of existing lines and £420,000 in respect of the construction of authorised lines as well as sums in respect of cars, car-sheds, sub-stations and certain other general items. The estimated total capital outlay of £13,500,000 is £1,150,000 more than the estimate made two years ago, the increase being due to new tramways authorised by Parliament in 1908 and 1909, the purchase of further tramway undertakings, the reconstruction of certain horse tramways on the conduit system instead of on the surface contact system, the increased amount chargeable to the tramways account in respect of street improvements, the extension of the central car repair depot, the provision of additional spare cars and additional car-shed accommodation, &c. The estimates provide for expenditure on tramways in 1910-11 of £1,500,000. If the expenditure reaches this estimate, there will remain to be expended after the end of the present year only about £1,300,000. In view of the heavy cost of widenings involved and the altered traffic conditions, it may be necessary to abandon parts of the remaining horse lines which are not of importance, and some allowance has been made for this in arriving at the total figure for capital expenditure of £13,500,000. The authorised new lines not yet constructed are small, and depend partly upon arrangements to be made with tramway authorities outside the county. The

Digitized by Google

£13,500,000 does not include anything in respect of the proposed new tramways for which powers are being sought in the present session of Parliament. Other schemes of tramways extension are under consideration which, if sanctioned, will in due course involve further considerable outlay.

The estimates for 1910-11 are based upon an estimated car-mileage of 45,356,000, and from the latest information available it appears that the annual car-mileage in 1913 may reach 52,414,000. On the basis of a surplus on working of 5d. a car-mile the committee estimate the probable result in 1913 will be somewhat as follows—Surplus on working, £1,091,958. Debt charges (interest £372,000 and repayment of loans £432,000) £804,000, less £650 in respect of Harrow-road tramways, which will be paid by the Metropolitan Electric Tramways (Ltd.), or £797,500 net, plus income tax £16,000, or a total of £813,500, leaving a surplus of £278,458, less renewals (¾d. per car-mile) £145,594, or an available surplus of £132,864. These figures must be regarded as a rough forecast only. The lines already electrified include the best paying portion of the system, and those which still remain as horse lines include a considerable proportion which, although of advantage as part of the general tramway system, have never been regarded as in themselves remunerative. Their electrification will involve large expenditure for street widenings. Moreover, several of the extensions now in hand although needed for the convenience of the public are not likely to prove remunerative at the outset. In addition a considerable amount remains to be expended for the completion of the central car repair depot, and although this centralisation of work will no doubt tend to keep down the cost of repairs, the expenditure involves heavy debt charges which will fall upon the existing revenue of the undertaking.

PARLIAMENTARY INTELLIGENCE.

L.C.C. GENERAL POWERS BILL.

This week the Local Legislation Committee of the House of Commons has been considering this Bill, which seeks to amend the Public Health (London) Act, 1891, with a view to the more effective abatement of the smoke nuisance. Sir F. Layland-Barratt was in the chair. The clauses dealing with the matter were opposed by West Ham Corporation, the L. & N.W., Central London, and Underground Electric Railways Co. of London, the Gas Light & Coke Co. and the South Metropolitan Gas Co., the London Chamber of Commerce and the Port of London Authority.

Mr. FitzGerald, K.C., said that at present proceedings for a smoke nuisance could be taken under the Act of 1891 only if the smoke issuing from a chimney in sufficient quantities to create a nuisance was "black." Two years ago a summons in the case of the Lot's-road station was dismissed because the smoke complained of was dark brown or dark grey. It was proposed to amend the Act by omitting the word "black," and thus bringing the law in London in line with that of Scotland. Hitherto Crown factories and workshops had been exempt from proceedings for creating a smoke nuisance, but it was now proposed to bring them within the scope of the Act. The Crown works most complained of were the Arsenal, the Dockyard, and the Small Arms Factory at Woolwich. The Treasury and the Home Office objected, and it would be for the Committee to decide whether those objections justified a continuance of the present immunity. It was also proposed to empower the County Council to take proceedings where a nuisance was created on the borders of but outside the county, by which people living within the county were affected.

Mr. C. C. Hutchinson, who appeared for some electric lighting companies and the London Chamber of Commerce, argued that there was no real smoke nuisance from factories and works in London, and that such nuisance as there was resulted from the burning annually of 5,000,000 tons of bituminous coal in household grates.

Dr. H. A. Des Voeux said that they were doing well under the present law in abating the smoke nuisance, but they were not doing sufficiently well. The Smoke Abatement Society had done their best to stir up the County Council to further action, but this was not the society's Bill.

On Wednesday Mr. Chas. H. Merz gave evidence on behalf of the Underground Electric Railways Co. of London. He objected to the omission from the Bill of the word "black," on the ground that too much power would be placed in the hands of permanent officials of the local authority, and that a great hardship would be imposed upon owners of factories and workshops. Large interests ought to have definite protection, so that local authorities could not be unreasonable. The omission of the word "black" would also interfere with the construction of large generating stations, which, in the aggregate, did a good deal towards reducing the amount of smoke.

Mr. Balfour Browne, K.C. (on behalf of the Underground Railways Co. and other petitioners) said he desired to insert in the Bill certain words which would exempt from penalty those undertakings which, having the best practical installations and using them in the best practical manner, could not prevent on certain occasions the emission of smoke which might be a nuisance.

Mr. Lloyd, K.C. (for the Central London Railway), also opposed the provisions of the Bill; and Mr. Evan Parry, gave evidence against it on behalf of the company.

It was pointed out that a statutory company was at present subject to the law in regard to smoke nuisance; and, on the suggestion of Mr. Fitzgerald, K.C., a sub-clause, which brought statutory companies within the scope of the Bill, was struck out.

Mr. Balfour Browne, K.C., for the Gas Light & Coke and South Metropolitan Gas Companies, said that if the law were altered in such a way as to make the emission of smoke, other than black, a matter of punishment, gas companies could not possibly carry on their undertakings. Therefore, he asked that the companies should have either the protection of the existing Act, which said "black" smoke, or an exemption clause inserted in the Bill.

Other evidence having been given in opposition to the Bill, the Committee adjourned.

L.C.C. TRAMWAYS AND IMPROVEMENTS BILL.

A Select Committee of the House of Commons (presided over by Mr. Soames) has been considering this bill during the past week.

Mr. A. L. C. Fell, chief officer of L.C.C. tramways, described the advantages of extending the Tooley-street line to Duke-street, London Bridge. The line from Greenwich to the proposed terminus would be 1⅛ miles shorter than the existing Old Kent-road route to Southwark Bridge. The extension would bring the tramway into direct communication with the railway stations at London Bridge, and would enhance the value of the line and its connections. His estimate of the net surplus (after allowing for capital charges) on the working of the extension was £143 a year.

The scheme was opposed by Hay's Wharf (Ltd.) and others on account of interference with the provision trade, &c.

The Committee found the preamble of the bill proved insofar as it related to the Tooley-street extension, upon the County Council undertaking to include in a bill next session certain road alterations to meet suggestions made by the police.

A clause was agreed to under which the proposed extension along Dulwich-road would not be opened for traffic until the entrance to Brockwell Park had been set back and the thoroughfare there widened in accordance with a marked plan. Lambeth Council had agreed to contribute £500 towards the cost, on the completion of the work.

On Wednesday the Chairman said the Committee had visited Dulwich-road, Herne Hill, and they strongly objected to the proposal to carry a line along that road 2½ ft. from the kerb. They suggested that either the boundary of Brockwell Park should be set back or the line should be single for a short distance.

The matter was deferred to allow the committee of the Council to consider the propriety of widening the road by taking in a strip of the park.

Mr. Pollock next described the proposals for tramway extension and reconstruction and street improvements in North London. The most important of these was a line from New North-road along the western end of Baring-street and along a new street to be constructed on the northern side of the Regent's Canal, and then along the eastern end of Baring-street to Southgate-road. The horse tramway up the narrow thoroughfare, Bridport-place, would be got rid of. Various reconstructions were proposed, and throughout the conduit system of traction would be adopted. The reconstructions included the St. Paul's-road, Islington, to City-road line, and the Green-lanes to Southgate-road line.

Mr. W. F. Dewey, town clerk of Islington, and the Borough Engineer gave evidence as to the interference with footways in the borough for tramway purposes, and they objected that the scheme would not allow sufficient width for the safety of pedestrians.

The Committee adjourned.

LONDON UNITED TRAMWAYS BILL.

This bill, which came before a Committee of the House of Lords on Wednesday, proposes to extend for one year from August next the time for the electrification of a tramway over Kew Bridge, which connects the Richmond and Kew system with the Hammersmith system of the London United Tramways (Ltd.), and to allow the use of overhead wires, subject to the sanction of Richmond Corporation. Middlesex County Council opposed on the ground that the use of the trolley system would be detrimental to the strength and appearance of Kew Bridge, and they claimed the right to decide what system should be adopted.

The Committee allowed the bill to proceed, and refused to insert the clause asked for by the Middlesex Council.

YORKSHIRE ELECTRIC POWER BILL.

This bill came as an unopposed bill before Mr. A. Emmott, Chairman of Committees, in the House of Commons on the 16th inst.

It was explained that the company was incorporated in 1901, and authorised to supply electricity in bulk over a large area of Yorkshire. The company had raised a considerable proportion of its £2,000,000 capital by ordinary shares, and it was proposed to give power to divide the capital into classes of shares, to be charged on new portions of their undertaking.

Mr. A. Lupton, chairman of the company, explained that the capital issued was £266,000 of ordinary stock, the whole of which was paid. They wanted further capital to meet increasing demands for power from manufacturers.

Mr. W. B. Woodhouse, the company's engineer, gave evidence as to clause 6, which would allow the company to subscribe for or hold shares or stock in any undertaking to which they were proposing to give a supply of energy.

The Committee considered that the provision would make the company a money-lending corporation, and restricted the lending to electrical undertakings authorised by Parliament.

The bill was then ordered to be reported to the House.

Post Office Telephone Service.—In the House of Commons on Tuesday Mr. Sherwell asked the Postmaster-General why the average cost per P.O. telephone station construction was £22 to £23 more per station than the National Telephone Co.'s average (as stated by the company's chairman.

Digitized by Google

In reply, Mr. SAMUEL said the chairman of the company had overlooked the fact that the P.O. expenditure included about £1,000,000 expended in providing plant for the use of the company, although he had previously mentioned the rent paid by the company for part of that plant. That sum should, therefore, have been added to the company's expenditure, raising the average cost by about £2 a station. A corresponding deduction would reduce the P.O. expenditure by about £11. 10s. per station. Moreover, expenditure on land and buildings seemed to have been excluded from the company's cost per station, and included in the cost attributed to the Post Office system; while part of the Post Office expenditure was for plant to replace the company's overhead wires and cables, and some of their older exchanges after their system was taken over by the Post Office at the end of 1911. Further, about 65 per cent. of the Post Office stations were in London, where a very costly underground system had been provided.

LEGAL INTELLIGENCE.

The Attorney-General v. Leicester Corporation.

On Monday Mr. Justice NEVILLE delivered his reserved judgment in this case. His lordship said that defendants were the undertakers under the Electric Lighting Act, 1882 (and a provisional order granted thereunder) for the supply of electrical energy within the borough. They claimed the right to supply wires and fittings (including bells and motors) used for the consumption of such energy to persons taking energy from them under their order. They based that claim solely on the statutory powers vested in them under the Electric Lighting Acts and order. Their title to do these things, which admittedly had been done, was the main and important issue between the parties. Plaintiff alleged that, in addition to the acts which they claimed a right to do, defendants had supplied fittings to persons in respect of buildings within the borough who do not take energy from them, and in connection with buildings, and also to persons resident outside the borough. In the view of the case which he took that was not important, and he could dispose of the matter at once by saying that in his opinion plaintiff proved his allegations.

To come to the more important question, the extent of defendants' statutory power, he thought it unnecessary to consider the nature of the fittings and apparatus supplied by defendants to consumers. By sec. 18 of the Electric Lighting Act, 1882, the consumer had the right to use the electricity supplied for all purposes without interference by the undertakers. If, therefore, defendants were entitled to supply lamps to the consumers for lighting it seemed to him they must be equally entitled to supply apparatus for the use of the electricity in any other way. Defendants contended that their acts were justified as being part of the supply within the meaning of the Act (and order thereunder), or as being reasonably necessary or incidental to such supply. Sec. 10 of the Act of 1882 authorises undertakers to generally do all such acts and things for supplying electricity as may be necessary and incidental to such supply. The Act, having expressly given powers to do all such acts and things as may be necessary and incidental to the particular power to supply it seemed to him difficult to imply any further powers to do what was reasonably incidental to the power to supply. It might well be, however, that the words should be read as necessary or incidental to such supply, in which case the general powers expressly given would be identical with the general powers which would have been inferred had the Act been silent with regard to them. That consideration seemed to him, however, unimportant, for if the right to supply energy did not itself include the right to wire and fit the premises supplied, he thought the right could not be claimed as incidental. If there were a distinction between supply and use, so far as the undertakers were concerned, the acts done were clearly referable to the use, and not to the supply. He might say that, in his opinion, the Court was in no way concerned with the consideration of the desirability or undesirability of the powers claimed being vested in defendants; that was for the Legislature alone. Further, he thought it immaterial whether defendants had made a profit or a loss by the business. If it was ultra vires it was not the less so because it was commercially successful. Nor could the most brilliant success enlarge the powers of defendants. An analogy between the Acts relating to gas and electricity had been insisted upon as indicating the intention of the Legislature to bestow upon the undertakers under the latter powers with regard to the supply of electrical fittings and apparatus similar to those bestowed by the former with regard to pipes, burners, meters and lamps. In fact, however, secs. 13 and 14 of 10 and 11 Vic., chap. 15, gave express power in the case of gas, and there was no corresponding section in the Act of 1882; while sec. 18 of the latter Act expressly negatived the right of undertakers to prescribe any lamp or interfere with the use of electricity in contradistinction to the right to prescribe the burner given to the undertakers by sec. 18 of the Gas Act. He thought, therefore, that the analogy failed. He also thought that there was nothing in the sections of the Act of 1847 inconsistent with the construction of "supply" in the Act of 1882 contended for by plaintiff, namely, that it meant the supply of energy to the consumer at his terminal. Sec. 18, already referred to, plainly discriminated between supply of electricity and its use, and gave the undertakers no authority with regard to the latter. When they turned to the provisional order the interpretation, in his opinion, became still plainer. "Consumer's terminals" was stated to mean "the ends of the electric lines situate upon any consumer's premises and belonging to him at which the supply of energy is delivered from the service line." The undertakers had power to charge for supply of energy and for meters and fittings, but for furnishing and laying lines they had no power to charge, except in special cases, by clause 21 of the provisional order. However, they were bound to give a supply of energy on demand, and if the wiring of the house and provision of fittings was part of the supply, they would be compellable to do it without remuneration, and he thought there was force in plaintiff's argument that that could not have been intended by the Legislature. In his opinion "supply" within the meaning of the Act and order was completed at the consumer's terminals. The "installation of electricity" and provision of fittings was, in his opinion, a separate business incidental to the use, but not to the supply, of energy. He thought that defendants had misinterpreted their powers and had been carrying on a business in excess of them. In his opinion the Act of 1909 did not throw light upon the meaning of "supply" in the Act of 1882, sec. 16 not having, in his opinion, reference to any power given by the Act of 1882. He thought plaintiff was entitled to the declaration asked for in para. 1 of the claim and to an injunction in the same terms. Defendants must pay the costs of the action.

Mr. DANCKWERTS said his clients would like to consider whether they would carry the matter further. He asked for the suspension of the injunction.

Mr. Justice NEVILLE: Certainly, if notice of appeal is given within reasonable time—within three weeks, and duly prosecuted.

Mr. DANCKWERTS: I take it the injunction will be general.

Mr. Justice NEVILLE: I think the injunction ought to go in the form asked under the Act, because there were those minor matters, but he did not think it mattered much.

"Z" Electric Lamp Mfg. Co. (Ltd.) v. Marples, Leach & Co. (Ltd.)

On Saturday in the Court of Appeal (the Master of the Rolls and Lords Justices Farwell and Kennedy) plaintiffs asked for an order for the security of costs of the appeal which defendants had entered from the judgment of Mr. Justice Parker, which granted an injunction to restrain defendants from infringing plaintiffs' patent for improvements in the manufacture of filaments for incandescent electric lamps.

Mr. WALTER, K.C., for plaintiffs, stated that defendant company was in liquidation, and it had been agreed that security should be found for the costs of the appeal in £200 within 10 days.

Mr. THOS. T. TERRELL, K.C., for defendants, pointed out that his clients had paid the taxed costs in the Court below.

Their lordships assented to the arrangement.

Overhead Telephone Wires.

Last week Judge Harington delivered his reserved judgment (at the Croydon County Court) in the dispute between Croydon Corporation and the Postmaster-General in regard to the erection of overhead telephone wires in 17 roads in Croydon and Norbury. In the course of his judgment, his Honour remarked that the Postmaster-General declined to accede to the request of the Corporation to put the wires underground on the ground of expenditure, the difference in the cost for the roads in question working out at £726. 17s. 7d. The Postmaster-General had already spent £65,000 on underground wires in the district, and only £1,800 on overhead. It seemed to him that telephonic communication was quite as important and necessary as telegraphic. The Corporation said the poles and wires would have the effect of lowering the letting value and depreciating the selling value of house property in the roads concerned; that they would be a source of danger in times of storm and tempest, and that they would be obstructions to the traffic. He did not think much weight could be seriously attached to the objection as to danger, which was very small indeed. Neither was there any substance in the objection that the humming noise disturbed the domestic peace and comfort, while the objection that they would increase the danger to the traffic was somewhat far fetched. There was no evidence to support it, and the same objection might apply to trees which were planted on the footpath.

The evidence as to the depreciation of property was unconvincing. House property had depreciated in the Croydon district during the last 10 years, but there was no evidence to show that the result of the late Judge Russell's award, in a similar arbitration, had depreciated the property in the roads affected. The objection that the poles would be a disfigurement was really the fundamental one which induced the Corporation to refuse their consent to the proposed works. He did not attach any great weight to those objections, and although the Corporation had canvassed all the roads, less than 50 per cent. of the residents had objected. The result of his award must be in favour of the Postmaster-General in every case, subject to conditions 1, 2, 3 and 4 in the award of 1907. As to condition 2, he thought that 30 wires should be substituted for 36, and in each case the poles and wires should be fitted with appliances to prevent the humming noise caused by vibration.

Jones v. National Telephone Co.

In the City of London Court on Friday plaintiff (Mrs. E. Jones), owner of a freehold house in South Lambeth, claimed an injunction and £5 damages against the National Telephone Co. for attaching "a telephone appliance" to her chimney stack.

Mr. GOODMAN, for plaintiff, said that plaintiff let the house to one Nicholls, who had a telephone put on without plaintiff's knowledge. He left, and then the company persuaded his successor to sign a wayleave, although he did not want the telephone, and, later on, they sent him a

Digitized by Google

crossed cheque for 1s. for a year's rent. The freeholder objected, and wanted the telephone attachment removed, as the roof was being damaged.

Mr. GAINE, for the company, said he had never heard that a tenant could not permit a telephone to be fixed or remain on his premises.

Judge RENTOUL, K.C., thought a tenant could have a telephone put on without the landlord's approval.

Mr. GOODMAN: No Parliament would give any telephone company such a right as is contended for without the freeholder's leave. The company had paid a guinea into Court, with a denial of liability.

Mr. GAINE urged that that was amply sufficient to recompense plaintiff. Her reversionary interest had not been damaged; hence she had not suffered. The tenant could give the company six months' notice to remove the telephonic attachment.

Judge RENTOUL suggested a compromise, and the parties agreed that the telephone should be removed within a month, no costs on either side.

MUNICIPAL, FOREIGN & GENERAL NOTES.

APPOINTMENTS VACANT AND FILLED.

The Governors of Robert Gordon's Technical College (Aberdeen) are about to appoint an engineer graduate of distinction as head of the engineering department of the college. Salary £500 per annum. Applications to the principal (Mr. Chas. Stewart, M.A.), by July 16. See also an advertisement.

The governors of the Technical Institute, Loughborough, invite applications for the position of lecturer in engineering subjects. Commencing salary £120 per annum. Particulars from the Principal, to whom applications should be sent by July 3. See also an advertisement.

A first-class electrical engineer is wanted, with experience in the design of c.-c. machinery. See advertisement.

A competent selling electrical engineer is wanted at once for India. See an advertisement.

Two or three first-class draughtsmen and two or three juniors are required for works in London. See an advertisement.

An instructor in engineering subjects is required at the Victoria Institute Science and Technical Schools, Worcester. Salary £150. Applications to Mr. Thos. Duckworth, Victoria Institute, Worcester, by June 29.

Applications are invited for the position of secretary in the Birmingham Corporation electric supply department. Applicants should have had a sound commercial training in some large mercantile or manufacturing concern, and a certain amount of technical knowledge in connection with electricity supply is also required. Salary £600 per annum. Applications to the city electrical engineer, Mr. R. A. Chattock, M.I.E.E., 14, Dale End, Birmingham, by July 1.

Mr. Harry Webber, assistant electrical engineer at Sunderland, has been appointed borough electrical engineer at Keighley, at a commencing salary of £250 per annum. There were 123 applications.

Mr. C. E. C. Shawfield, borough electrical engineer and general manager of the electricity works at Wolverhampton, has been retained as consulting engineer of the tramways department, and Mr. H. Vickers has been appointed tramway engineer and chief assistant to the general manager at £200 per annum.

Mr. J. Hayward Home has resigned his position as engineer and manager of the Berwick-on-Tweed electricity works in order to take up the position of managing director of the Kenyon Ironworks Co. (Ltd.), Manchester.

EDUCATIONAL NOTICES.

City and Guilds of London Institute.—The entrance examinations of the City and Guilds Central Technical College, Exhibition-road, S.W., and the City and Guilds Technical College, Finsbury, E.C., are held in September, and the sessions commence in October.

Both institutions provide courses of instruction in engineering, chemistry, mechanics and mathematics, &c. Particulars of entrance examinations, scholarships and courses of study may be obtained from the respective colleges or at the head offices of the Institute, Gresham College, Basinghall-street, London, E.C. The Central Technical College is intended for higher technical instruction for day students not under 16 years of age, preparing to become civil, mechanical or electrical engineers, chemical or other manufacturers and teachers. The college is a school of the University of London, and forms the engineering section of the Imperial College of Science. The courses of the study for the associateship of the Institute cover a period of three years.

The City and Guilds Technical College at Finsbury (London, E.C.) is designed for day students preparing to enter engineering and chemical industries and for those who have already served an apprenticeship and also for evening students. The day courses in mechanical or electrical engineering cover two years and those in chemistry three years.

Heriot-Watt College (Edinburgh).—This college provides theoretical and practical training for mechanical, electrical and mining engineers, technical chemists, brewers, &c., and printers and publishers. The training for engineers consists of three years in the college and a three years' apprenticeship on the "Sandwich" system in a local engineering works. The course in mining extends over two years, and the training is also recognised by the University of London for the B.Sc. degree in mining. Complete courses of instruction, extending over four years, are provided for students studying for the fellowship of the Institute of Chemistry, &c. An entrance bursary of £25 will be offered for competition on Sept. 27 and 28 next. Particulars of fees, &c., may be obtained from the principal, Mr. A. P. Laurie, M.A., D.Sc.

Education Bequests.—The late Prof. Jas. Campbell Brown, of Liverpool University, left estate valued at £43,101. 19s. 5d., with net personalty £42,740. 2s. 1d.

He bequeathed £25,000 to £28,000 for a professorship at the University of Liverpool (or, alternatively, at the University of Manchester); £1,500 for an advanced chemical scholarship at Liverpool; and from £5,000 to £8,000 for an entrance scholarship for chemistry in Liverpool University.

Aldershot.—An unopposed inquiry was held last week into the Council's application for sanction to borrow £1,500 for electric supply mains, services, &c.

In the course of the inquiry the inspector (Mr. H. ROSS HOOPER) raised the question of the pooling of loans, and in reply

The clerk (Mr. W. E. FOSTER) said that the pooling of loans had taken place because the business had been all the time increasing, and the necessary money required by the department had not been to hand.

The INSPECTOR: You will have to start perfectly clear. You must pass a resolution that the expenditure on each loan must be spent separately, and there must be no more pooling of loans. He noticed that during the eight years the Council had conducted the undertaking it had not cost the ratepayers anything. He did not think they need allow the fact of their having a small balance on the wrong side to trouble them to any great extent, because, after all, that was not so important as that they should carry on the undertaking in a financially sound way, and that they should have no trouble or difficulty with their capital.

Argentina.—The "Financial Times" states that the first section of the extended system of the Buenos Ayres Port and City Tramway Co.'s electric tramways in the Avellaneda district will be opened at an early date, and the whole of the new track (over 13 miles) should be in operation before the end of this year. There has already been a great increase in this company's traffic receipts, chiefly due to the fact that a contract under which coal and general freight is carried for the Cia Alemana Transatlantica de Electricidad has come into force.

Battersea (London).—The electrical engineer (Mr. F. A. Bond) has reported on the experiment made by him in the use of carbon brushes in place of wire gauze brushes for the turbine generator sets.

Mr. Bond states that by adopting carbon brushes the machines are more reliable and efficient, and the Electricity committee have decided that the necessary works be carried out for providing and adapting the gear for carbon brushes to the remaining turbine generator sets at a cost of £85. 10s.

Application has been made to the L.C.C. for a loan of £18,900 for extensions of mains, &c.

Bundoran (Ireland).—Messrs. John Myles & Co. are erecting an electricity supply station in this town.

Canadian Railway Electrification.—It is stated that the Canadian Pacific Railway Co. propose to electrify their terminals at Montreal.

Cardiff.—At the meeting of the Tramways committee last week the borough electrical engineer (Mr. Arthur Ellis) suggested the adoption of the rail-less trolley system to serve outlying districts, such as Whitchurch, Llandaff, &c. The system, he said, would act as a feeler for a future extension of the tramways of the city. The matter was referred to the Parliamentary committee.

The late Ald. P. W. Carey's long service as chairman of the Electrical and Tramways committee was referred to by Mr. J. W. Courtis and Ald. Illtyd Thomas, and a vote of condolence was passed with Mrs. Carey. Mr. Courtis mentioned that Ald. Carey was appointed chairman of the committee in 1899. Mr. J. W. Courtis (deputy-chairman) was unanimously elected chairman to succeed Ald. Carey, and Mr. H. C. Vivian was elected vice-chairman.

Devonport.—The Electric Power committee again recommend that the net profit on the past year's working of the electricity department be placed to reserve, and also that the salary of the borough electrical engineer (Mr. J. W. Spark) be increased from £300 to £350 per annum by two annual increments of £25 each.

Electrical Engineer's Bravery.—On the 15th inst. the Royal Humane Society awarded a silver medal to Mr. George R. Drummond, electrical engineer to the Maharajah of Bikaner, Rajputana,

Digitized by Google

India, for his gallantry in saving one man and attempting to save two others who were rendered unconscious in a well 320 ft. deep. Three times Mr. Drummond went down, each time bringing up a man, and he himself then collapsed, but recovered later.

Fleetwood (Lancs.).—The electrical engineer (Mr. W. H. Miller) has been instructed to prepare estimates of the cost of lighting the whole of the streets by electricity.

Freshwater (Isle of Wight).—At the last meeting of the Parish Council Mr. Parker urged the members to take steps to improve the place by adopting electric lighting, &c. He suggested that the engines at the pumping station might be utilised in the generation of electrical energy. A motion to consider the matter was carried.

Greenock.—On Tuesday the Corporation adopted a recommendation of the Electricity committee to increase by £50 per annum the salary of the burgh electrical engineer (Mr. J. A. Robertson).

In moving the adoption of the recommendation, the convener (Councillor BAILEY) said it was only just to Mr. Robertson to mention that he did not ask for an increase. Neither did he make it a pretext for an increase that he had applied for the position of borough electrical engineer at Salford. Mr. Robertson had intended, after the end of the financial year, applying for an increase of salary, but at present he had made no such request. He referred to the ever-increasing amount of work Mr. Robertson had on hand, and argued that at the present time it would not be in the best interests of the Corporation and of the ratepayers if Mr. Robertson's services were lost to the community. An increase of £50 would be a very small price to pay for retaining Mr. Robertson's services, and he understood that if the Corporation approved of the recommendation Mr. Robertson would withdraw his Salford application.

Hampstead (London).—The receipts of the electricity undertaking for the year ended March 31 were £60,270, against £62,879 in 1908-9.

The Electricity committee reported last week that they had had under consideration the question of carrying out a further portion of the works recommended by Sir Alex. Kennedy, and they recommended that further plant be installed at the station at a cost of £6,600 (condensers £3,100 and cooling towers £3,500). The recommendation was agreed to.

Hindley.—The Council have applied for an extension of time for carrying out their provisional electric lighting order.

Inquest.—An inquest was held on Tuesday into the death of Wm. H. Brown, who was killed at the Powell Duffryn Colliery on 17th inst.

Evidence was given that deceased went to remove some oil boxes near the switchboard when his hand came in contact with the plunger, and he received a shock. The voltage of the current was 1,750. The removal of the boxes without switching off the current was contrary to the Home Office Regulations. Deceased had not been instructed to remove them.

Mr. LLOYD (the electrician), in answer to Mr. Carey, inspector of mines, said deceased had an oil can in his hand at the time of his death, and was probably going to attend to the boxes. A verdict of death by misadventure was returned.

Leeds.—The Tramways committee have entered into a contract for the conveyance of between 20,000 and 30,000 tons of sand and gravel for the new beds at Headingley. The waggons will be equipped with the standard motors and braking equipment of the department.

Leicester.—The Gas and Electric Lighting committee have decided to advertise for an engineer and manager of the gas works in succession to the late Mr. A. Colson, and the electricity supply department will be placed under separate and independent management.

Llandudno.—The Council have decided, after two years' experience of incandescent gas lamps on the Promenade, to remove the temporary gas standards and to restore the electric arc lamps. Tests are to be made to determine whether ordinary arc or yellow flame lamps should be adopted.

Lowestoft.—The general manager of the tramways department (Mr. G. A. Bruce) has been asked to report upon the practicability of adopting the railless trolley system on the Kessingland light railway.

Machinery Users' Association.—At the annual meeting last week the president (Sir Wm. Holland), in moving the adoption of the report, congratulated the Association on its continued success in the work which it undertook to do. As to legislation, he was glad to say that none had been passed in the last year which affected them as machinery users, except, perhaps, the Finance Act. The report mentioned the way in which machinery users were being treated by the rating authorities. In the manufacturing districts there was now, generally speaking, no reason for complaint. There were still some districts where they had difficulty. He regretted that they had not been able to obtain legislation dealing with the general question of rating, but the present state of affairs in Parliament had made it impossible for them to introduce again the Rating of Machinery Bill, and a further reason was that a more uniform system was being brought about in connection with rating.

Nelson.—The offer of Burnley Corporation to supply electricity at 2d. per unit for the tramways has been accepted by Nelson Council.

New Submarine Cable.—On the occasion of the establishment of the first submarine telegraph connection between Germany and Africa (at Monrovia, Liberia) the German Emperor telegraphed his congratulations to the Secretary of the Post Office, and to the Nordeutsche Seekabelwerke, the makers of the cable.

Norwich.—An unopposed inquiry was held on Tuesday into the application of the Corporation for sanction to borrow £17,783 for extensions of the electricity undertaking.

The TOWN CLERK (Mr. A. H. Miller) said that since the last inquiry in 1907-8 the number of consumers had increased from 4,425 to 4,692. The undertaking was acquired by the Corporation in 1903-4, when there were 3,010 consumers. The loan was required for an exhaust steam turbine with condenser, steam exhaust and water pipes, generator, switchgear, &c. (£5,000), centrifugal pump for circulating water (£200), balancer (£160), coal elevator (£150), bye-pass flue from new boiler to shaft (£70), Patersen feed water filter for dealing with 4,000 gallons per hour (£203) and mains and services (£12,000).

The electrical engineer (Mr. F. M. LONG) supplied technical details. The total capital expenditure at March 31 was £312,374, the total amount of capital sanctioned being £311,758. The net profit up to 1908-9 was £3,678.

The Inspector (Mr. H. Ross HOOPER) said he should like to draw the committee's careful attention to the question as to how far they were saving by borrowing money for services at all, and how far they were incurring additional expense by reason of capital repayment and interest.

The chairman of the Electricity committee (Mr. WILD) said he gathered that the Inspector deprecated the dispersion in rate aid of money that might be made by the undertaking.

The INSPECTOR: Your engineer would be able to give you better advice than I could; but the first principle was to be absolutely financially sound, and the next was to bring the capital down so as to be able to give the cheapest supply for the benefit of consumers.

Mr. WILD: I anticipated your answer. I asked the question really to strengthen our hands in the position we have taken up in committee. The only time we departed from our principle was last year, when £1,200 was practically wrung from us.

The INSPECTOR: It spoils your undertaking, and does little or nothing for the rates. Your engineer will know better than I do how necessary it is to build up a private reserve, especially having regard to the fact that you paid a considerable amount to the company for the undertaking.

Obituary.—The death of Mr. J. T. Mayfield recently occurred at Clacton-on-Sea. Deceased was trained as a chemist, and acted for some years as assistant to Sir Joseph Wilson Swan. After leaving Sir Joseph Wilson Swan's service he set up as a chemist, but abandoned this for electrical engineering.

Pembroke (co. Dublin).—An inquiry was held last week into the Council's application for sanction to borrow £8,000 for extensions of the electricity supply undertaking.

The electrical engineer (Mr. S. L. R. PRICE) said the proposed extensions were necessary to meet the demands of actual customers and they were also providing for additional customers. They had 763 consumers. The total revenue last year was £7,547, an increase of £614. The use of electricity for cooking and heating was increasing.

Penmaenmawr.—The Council have decided to adopt electric lighting on the promenade.

Personal.—Mr. John Newlands, C.I.E., deputy controller of the Central Telegraph Office, will succeed the present controller (Mr. Eames) when he retires at the end of this month.

Mr. Newlands, who was born at Innerleithen, Peeblesshire, in 1857, entered the telegraph service at Edinburgh, and passed through the various grades, finally being appointed controller there in 1893. From Edinburgh he was promoted to be traffic manager of telegraphs, and while occupying this position visited many towns in the United Kingdom, and he also crossed the Atlantic to visit the most important telegraph offices in Canada and the United States. In 1905 he was offered the position of deputy-controller at the Central Telegraph Office, St. Martin's-le-Grand, London, and after about two years' service in this position he was lent to the Indian Government for reorganising the traffic arrangements of the telegraph department in India. He was occupied on that mission for two years, during which time he traversed the whole of India and Burma, where he introduced many reforms. For these special services he received the decoration of C.I.E. During his stay in the East Mr. Newlands, at the request of the Colonial Office, also visited Ceylon, effecting great improvements in the telegraph system of that colony.

Presentation.—The staff and employés of Kettering electricity department have presented a barometer to the electrical engineer (Mr. W. A. Walker) on his marriage.

Radcliffe.—The Board of Trade have now given their decision, after holding a local inquiry, on the application of the Lancashire Electric Power Co. for a provisional order to supply electric current in the town for power, although the Council possess electricity supply works. The Board have decided in favour of the Council, and the company's application for an order has been refused.

The Board, however, state that, from the evidence produced at the inquiry, it appeared to them that the facilities afforded to power users in Radcliffe to obtain a supply of energy at a reasonable rate were inadequate, and, in the opinion of the Board, should be promptly extended. In the event of the company making fresh application in respect of the district at some future date, and on it being shown to the Board that the

Digitized by Google

demand for energy for power is not being adequately met, the Board may find it necessary to arrive at a different conclusion to that now conveyed.

The new offices of the Council are to be wired.

Rawtenstall.—The Corporation have applied for sanction to a loan of £11,000 for their electricity undertaking.

Surbiton.—The Council have obtained sanction to a loan of £1,230 for services and meters.

Tramcar Design.—In order to secure additional accommodation on the lower decks of tramcars, Mr. C. W. Mallins, general manager of Liverpool Corporation tramways, has designed a new seating arrangement.

The seats are placed transversely on the lower as well as on the upper deck, thus securing the maximum accommodation. Another object secured is the alteration of the centre of gravity by making the width of the ground floor equal to that of the upper deck, thereby reducing the disagreeable side motion caused by the top-heaviness of the cars, and obtaining the maximum security. By this re-arrangement 6 additional seats are secured, 18 of the seats are transverse and 8 longitudinal. By placing the 8 seats longitudinally, 2 at each corner of the car, no interference with the sand boxes and lightning arresters is necessary. In the new car seats are provided for 64 passengers, 38 on the upper deck and 26 on the lower.

West Africa.—The "African World" states that satisfactory progress is being made with the scheme for the supply of electrical energy at Dakar, and that supply is expected to be available towards the end of this year. Electric driving will probably be adopted for pumping at the waterworks.

Wireless Telegraph Note.—It is announced that the results which have been attained from wireless telegraph stations established by the Admiralty in various parts of the kingdom have greatly exceeded anticipations, and that recently over a lengthy series of experiments in all conditions of weather the accuracy and reliability of wireless working has proved very satisfactory.

Workhouse Lighting.—Islington (London) Council are extending their electric supply mains to the workhouse of Shoreditch Guardians in Hazelville-road.

East Ashford Guardians have decided to collect information as to the electric lighting of their workhouse. The estimated cost of wiring and fitting is £350, and the annual cost £50.

Barnet Guardians propose to wire their workhouse at a cost of about £700.

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Buxton.—During the year ended March 31 last 316,030 units were sold (against 316,688 in 1908-9), including 271,436 for private lighting (against 275,288).

Total revenue of the electricity department was £5,565 (4·2d. per unit), against £5,631 (4·26d.); private supply receipts were £4,875 (3·702d.), against £4,944 (3·74d.). Works costs were £1,773 (1·34d. per unit sold), against £1,950 (1·46d.); total costs were £2,702 (2·05d.), against £2,851 (2·16d.). Interest absorbed £1,120, repayment of loans £1,984, and £244 was spent on new chain-grate stokers, leaving a deficit of £485.

Croydon.—The traffic revenue of the tramways department for the year ended March 31 was £83,030, and with miscellaneous receipts and interest £85,755.

Working expenses were £63,084, leaving a gross profit of £22,672 to meet interest on capital and income tax (£8,295) and sinking fund (£7,371). The net balance (£7,006) was carried to renewals fund. 18,705,604 passengers were carried and 2,253,710 car-miles run. The average fare per passenger was 1·065d. and the working costs 0·809d. 2,896,424 units of electrical energy were used, or 1·285 per car-mile. The ratio of working expenses to total revenue was 73·28.

Dover.—The capital expenditure on the electricity undertaking at March 31 was £187,194, an increase of £605 during the past year.

The total revenue was £21,651, and included £16,484 from the sale of current by meter and £3,833 from public lighting. The total expenses were £9,545 (2·08d. per unit, against 2d.), leaving gross profit £12,106 to meet interest on loans (£7,259), other interest (£448) and sinking fund instalment (£4,626), showing a deficit of £227. Applications were received during the year for the equivalent of 2,282 30 watt lamps, and the total connections are now equal to 52,269 30 watt lamps. The output to private consumers was 549,800 units, an increase of 11,530. The estimated net profit for the current year is £1,167.

Great Yarmouth.—The total revenue of the tramways department for the year ended March 31 was £23,324.

Total working expenses were £16,734 and gross profit £6,588. Interest came to £3,959 and sinking fund to £2,648, leaving a net profit of £68. 4,364,962 passengers were carried and 663,988 car-miles run, 686,389 units of current were consumed (1·033 units per car-mile), and the percentage of working expenses to traffic revenue was 72·20. Capital expenditure is £121,241.

During the year ended March 31st the capital expended on the electricity department was £2,183, making the total £101,714.

The total revenue for the year was £20,234 (against £20,386), including £10,011 from the sale of current for private lighting and power and £9,555 from Corporation departments. The total expenditure was £11,147 and the gross profit £9,087, but depreciation on expenditure for which loans have not been granted amounted to £948, leaving an available balance of £8,139 to meet interest (£2,728), sinking fund (£4,001), income tax, discounts, &c. The net profit of £649 (against £194 in 1908-9) has been carried forward. 1,610,554 units of current were sold (646,061 to private consumers, 684,867 to the tramways department and 245,811 for public lighting), and the total maximum supply demanded was 1,142 kw. There are 189 arcs and 266 osrams for public lighting.

Leeds.—The income of the electricity department for the year ended March 31 was £99,081, including £64,474 from private lighting, £4,881 from street lighting and £29,669 from power and heating.

Gross profit was £69,586. Income tax required £1,120 and interest £28,031; redemption fund charges were £31,206 and wages of permanent men not chargeable to loan account £299, leaving a surplus profit. There are 6,026 lighting consumers (increase 394) and 1,127 power and heating consumers (increase 169), with the equivalent of 311,812 and 320,917 35-watt lamps connected (a decrease of 1,815 and an increase of 72,374 35-watt lamps respectively). There are 2,088 motors (increase 378) of 12,838 H.P. (increase 2,894 H.P.). 4,575,957 units were sold for private lighting (decrease 665,566), 937,193 for street lighting (decrease 51,592), and 6,908,014 for power and heating (increase 743,204). The units sold per 35-watt lamp (or equivalent) were 20·66 (against 22·91), the average price per unit was 1·91d. (against 2·02d.), and the revenue per 35-watt lamp was 3s. 3·55d. (3s. 10·20d.). Total working expenses were 0·59d. (against 0·67d.), and total expenses (including interest, redemption fund charges, &c.) were 1·74d. (against 1·86d.), the surplus profit being 0·17d. against 0·16d.). The capital expended during the year was £22,521, bringing the net capital to £749,265 (£47. 12s. 1d. per kilowatt installed).

Though the increase in the number of consumers for lighting was greater than for several years past, the number of 35-watt lamps installed shows a decrease, owing to the replacement of carbon by metal filament lamps, and the revenue from sales of current to private consumers for lighting shows a reduction of 12 per cent. Notwithstanding local trade depression, the sale of energy for power and heating shows a greater increase than in any previous year. The net surplus on the year's working (£8,930. 18s.) is greater than in any previous year, and has been devoted to relief of rates, making the total contributions to rates fund to date £54,797. 11s. 4d. The maximum load was 8,900 kw., against 8,220 kw.

Stockton-on-Tees.—The income of the electricity supply department for the year ended March 31 was £8,130. 10s., and included £7,835 net from the sale of current for private and public lighting.

Expenses were £4,219 and gross profit £3,911. 10s. After paying interest and providing for repayment of loans, the balance (£639. 12s. 9d.) was placed to reserve. The total capital expended is £54,271, an increase of £253 on the year. 771,255 units were sold for private lighting and 66,343 for the public lamps.

TRADE NOTES AND NOTICES.

TENDERS INVITED.

Tenders are invited by July 6 for the supply of cordless switchboards to the Postmaster-General's Department in SOUTH AUSTRALIA. Tender forms and specification may be obtained at the Commonwealth Offices, 72, Victoria-street, London, S.W. See also an advertisement.

Tenders are invited for the supply to the Postmaster-General's Department, NEW SOUTH WALES, of one dust extractor electrically driven, to work on a 24-volt d.c. circuit. Tender forms, &c., from the Commonwealth Offices, 72, Victoria-street, London, S.W. See also an advertisement.

Tenders are invited up to Aug. 2 for the supply and delivery of 1,820 private letter box fronts to the Postmaster-General's Department in the States of VICTORIA, QUEENSLAND, SOUTH AUSTRALIA and WESTERN AUSTRALIA. Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W. See also an advertisement.

CROMPTON Council want tenders by 10 a.m. June 30 for supply of dynamos and other electrical equipment, including motors, wiring, lamps, &c., for lighting new and present buildings at New Hey sewage works. Specifications from Messrs. J. P. Wilkinson & Son, 301, Cathedral-street, Manchester.

BIRMINGHAM Corporation want tenders by June 30 for 12 months' supply of stores for their electricity department, including electrical accessories, ironmongery, &c. Particulars from the City Electrical Engineer.

RAWTENSTALL Corporation want tenders by July 1 for permanent way construction and supply of steel poles, overhead equipment, cables, conduits, &c., for a tramway. Specification from the Borough Engineer.

BATLEY Council require tenders by noon June 28 for supply of a battery of accumulators, an automatic reversible traction booster and a battery charging booster. Specifications from Borough Electrical Engineer.

LONDON County Council require tenders by 11 a.m. July 6 for electric wiring at St. Mark's-road and Haverstock Hill schools. Specifications from the Chief Engineer, Spring-gardens, S.W.

LLANDAFF and DINAS POWIS Rural Council require tenders by July 4 for e.h.t. switchgear, transformers, distributor switchboard, mains, &c., for electric lighting at Whitchurch. Forms of tender, &c., from Herbt. Lewis & Fletcher, St. Mary-street, Cardiff.

SALFORD Corporation require tenders by noon July 18 for a bore-hole pumping plant for their electricity works, Pendleton. Particulars from the Borough Electrical Engineer.

LONDON County Council require tenders by 11 a.m. July 5 for supply of 250 electric tramcar bodies and 250 electrical equipments for conduit and overhead systems. Specifications from the Clerk.

LONDON County Council also want tenders by 11 a.m. June 28 for supply of petrol or electrically-driven fire escape vans. Specifications, &c., from the Clerk.

Tenders are required by June 28 for supply of electric light and power plant and wiring at the County Asylum, Knowle, FAREHAM. Specification from the County Surveyor, The Castle, Winchester.

EALING Corporation require tenders by noon July 4 for supply and erection of surface condensing plant, &c., at the electricity works. Specification, &c., from Town Hall, Ealing.

Tenders are required for the installation of electrical plant in the vicinity of DUBLIN. Particulars from Mr. P. O'Hare, 15, Well Park-avenue, Drumcondra, on payment of 10s. 6d.

HORNSEY Council want tenders by 10 a.m. July 9 for the electric wiring and fitting of Stroud Green school. Specification, &c., from the Borough Electrical Engineer.

SHANGHAI Municipal Council invite tenders for supply and delivery (c.i.f. Shanghai) of two 940 k.v.a. two to three-phase step-up transformers, e.h.t. switchgear, e.h.t. underground mains and feeder pillars. Specifications from Messrs. Preece & Cardew, 8, Queen Anne's-gate, Westminster, S.W., to whom tenders before noon July 5.

Tenders are invited up to July 27 for supply of a pneumatic tube service to the Postmaster-General's Department at ADELAIDE (S. Australia). Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W.

Tenders are invited for supply of 36,000 incandescent electric lamps to the City of MELBOURNE. Specifications, forms of tender, &c., from the agents for the City Council (Messrs. McIlwraith, McEacharn & Co. Proprietary, Ltd.), Billiter-square Buildings, London, E.C., to whom tenders by noon July 1.

Tenders are invited up to July 19 for supply and delivery of 4,200 telephone sets (as per schedule No. 231) to the Postmaster-General's Department in VICTORIA. Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W.

The Turkish Ministry of Commerce and Public Works want tenders by Oct. 28 (Nov. 10) for a concession for the construction and working of electric tramways in CONSTANTINOPLE and suburbs. A deposit of £13,500 (sterling) is required with each tender. Local representation is essential. Copy of specification (in French) may be seen at 73, Basinghall-street, London, E.C.

The Société Nationale des Chemins de fer Vicinaux, BRUSSELS, want tenders by July 20 for underground cables, and by July 27 for the equipment of a transformer station.

The Ministerio de Fomento, MADRID, will receive tenders until July 30 for the construction of an electric (or steam) strategic railway from Requena to Alcaráz, via Casas Ibáñez and Albacete. The contract is open to Spanish firms only.

The Ministerio de Obras Publicas, SANTIAGO (Chili), will receive tenders until July 15 for the substitution of electric for steam traction on the first section of the Chilian State Railways—from Valparaiso to Santiago and Los Andes.

The Turkish Ministry of Public Works, Constantinople, will receive tenders until July 4 for a concession for the construction and working of electric tramways at SALONICA. Deposit of £2,250 sterling required with each tender. Local representation is necessary. Specification (in French) may be seen at 73, Basinghall-street, London, E.C.

Tenders will be received at the Driftsbestyrerens Konto, Electricitetsverk, HAMAR, Norway, until noon June 29 for supply of dynamos, oil transformers, cable, 6 tons copper wire, &c. Specifications (in Norwegian) may be seen at 73, Basinghall-street, London, E.C.

The Société Nationale des Chemins de fer Vicinaux, BRUSSELS, want tenders by July 27 for the complete equipment on the overhead electric system of the Brussels-Haecht section of the light railways.

NICE (France) Municipality want tenders by July 9 for the supply and erection of an electric lift for goods.

CHATELLERAULT (France) Corporation want tenders by July 27 for supply of incandescent lamps, copper, &c.

BOURGES (France) Council want tenders by July 7 for the supply of electric cables and wires.

TENDERS RECEIVED AND ACCEPTED.

Barnes (London) Council received the following tenders for supply of 4,000 yds. triple-concentric 0·25, 0·25, 0·125 sq. in. l.t. cable (paper insulated, lead sheathed, jute served and compounded):—

Siemens Bros. & Co. (*acc.*)	£1,600	W. T. Henley's Co.	£1,720
General Electric Co.	1,865	Standard Cable Co.	1,700
Callender's Co.	1,784	Lahmeyer Electrical Co.	1,680
W. T. Glover & Co.	1,730	Electrical Co.	1,680
Johnson & Phillips	1,722	Western Electric Co.	1,648
Brit. Insulated & Helsby Cables	1,722	Union Cable Co.	1,575
		Aubert, Grenier & Co.	1,560

The following tendered for motor-generator plant required by the Newport (Mon.) Corporation, the contract being awarded to the General Electric Co. as the lowest tenderers:—

General Electric Co., British Thomson-Houston Co., Dick, Kerr & Co., Johnson & Phillips, British Westinghouse Co., Brush Co., Lahmeyer Electrical Co., Crompton & Co., Siemens Bros. Dynamo Works, Electric Construction Co., Lancashire Dynamo & Motor Co., and Bruce Peebles & Co.

Hammersmith (London) Council recently accepted the tender of Ferranti, Limited, for h.t. switchgear at £155. 2s. 6d. and l.t. switchgear at £32. 10s., but as the firm intimated that they had made an error and that their tender for h.t. switchgear should be £256. 15s., the Council permitted them to withdraw their tender, and the tender of Cowans (Limited) has been accepted for h.t. switchgear at £217, and l.t. gear at £39. 10s.

St. Anne's-on-the-Sea Council have received the following tenders for supply of a fuel economiser:—

E. Green & Sons (*accepted*), A. Lowcock (Ltd.), Carter & Sons, Clay Cross Co., Roberts Bros. and Goodbrand & Co.

Norwich Corporation have accepted the tender of Willans & Robinson for a turbo-generator, condenser, oil separator, &c., at £3,758, on condition that the contract is completed by Oct. 1, 1910.

The Metropolitan Asylums Board have placed an order with W. J. Fryer & Co. for the installation of low-voltage metal filament lamps at Tooting Bec Asylum, at a cost of £350.

West Ham Education committee have accepted the tender of Pritchetts & Gold (at £75. 4s. 7d.) for renewing the plates at the main storage battery at the Technical Institute.

Battersea (London) Council have accepted the tender of Baxter & Caunter, at £63. 3s. 6d., for the supply of two motors at the Culvert-road Depot.

Bury St. Edmund's Corporation have accepted the tender of the British Westinghouse Co. for a 200 kw. steam dynamo (Belliss engine) at £1,083.

Huddersfield Corporation have accepted the tender of J. Marsden & Son for wiring the new schools at Birkby.

Islington (London) Council have accepted the tender of the Crown Engineering Co. (at £135. 10s.) for a lathe.

Burslem Education committee have accepted the tender of E. M. Evans & Son for wiring the new central schools at £200.

Auckland Guardians have accepted the tender of the Electric Motor Co. for wiring new infirmary at £112. 16s. 6d.

Southwark Council have accepted the tender of the General Electric Co. for an 8 H.P. slow-speed motor at £33.

Cleckheaton Council have placed an order with the Lancashire Dynamo & Motor Co. for an automatic reversible booster.

Burnley.—*A Correction.*—In reference to the note in our last issue (p. 413) as to the tenders accepted by Burnley Corporation for two single-deck cars, the contract for the electrical equipment was given to the British Thomson-Houston Co., and not to Messrs. Dick, Kerr & Co., as stated.

Water-Purifying Plant.—The Seck Engineering Co. have installed one of their standard type water-softening and purifying plants at the works of the Imperial Lamp Works, Brimsdown, Middlesex, for treating the feed of a Babcock-Wilcox boiler, under an absolute guarantee of immunity from the formation of scale at a fixed working charge, which it is also guaranteed shall not be exceeded.

Government Contracts.—The following tenders have been accepted by the Government Departments:—

Admiralty.—Evered & Co., Gabriel & Co., General Electric Co., Hawkes (Ltd.), Sir James Laing & Son, W. McGeoch & Co., Player & Mitchell, and Spagnoletti (Ltd.), for electric lamps, brackets, pendants, &c.; British Insulated & Helsby Cables, Edison & Swan Co., Electric & Ordnance Accessories Co., Evered & Co., Hawkes (Ltd.), India-Rubber, Gutta-Percha &

Digitized by Google

Telegraph Works Co., International Electric Co., Johnson & Phillips, Kelvin & James White, W. McGeoch & Co., Player & Mitchell, Reid Bros., Spagnoletti (Ltd.), Sterling Telephone & Electric Co., Walters' Elec. Mfg. Co., and A. Watson & Co., for switches, bells and other electrical fittings.

War Office.—Credenda Conduits Co., Edison & Swan Co., General Electric Co., S. Heath & Sons, Kensington Stamping Co., and Veritys Limited, for electric light fittings.

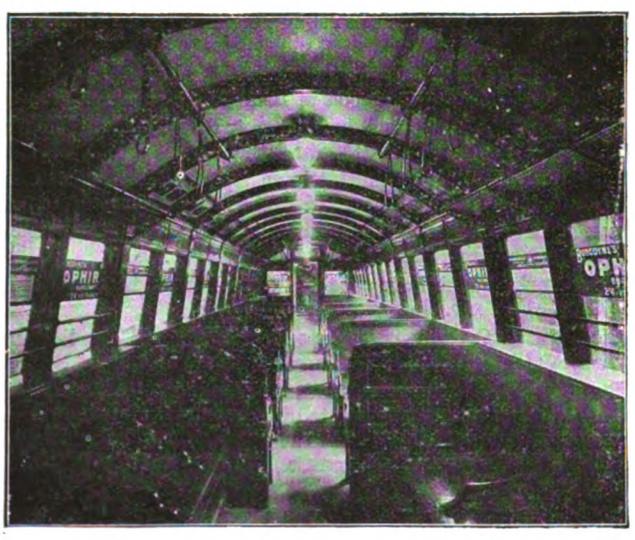
India Office.—C. & A. Musker, for electric cranes.

General Post Office.—Gell Telegraphic Appliances Synd., telegraph apparatus; British L. M. Ericsson Mfg. Co., magneto bells; Bullers (Ltd.), insulator spindles; Western Electric Co., telephones; F. Smith & Co., bronze wire; R. Johnson & Nephew, copper wire; London Electric Wire Co. & Smith's, flameproof wire; J. Gray & Son, electric lighting of Edinburgh Head Post Office; A. Maund, electric lighting of Western District Post Office, London; Western Electric Co., telephone equipment for private branch exchange lamp signalling system at Harrod's Stores; Shaddock Bros., laying and jointing iron pipes at Brighton; A. Schofield, laying and jointing iron pipes and earthenware ducts at Leeds; G. P. Trentham, laying and jointing iron pipes and erecting fire alarm pedestals at Manchester.

Sale by Auction.—Mr. W. H. Robinson will sell by auction at the Albion Hotel, Piccadilly, Manchester, on Tuesday, July 19, at 5 p.m., a plot of freehold land, containing about 5,089 sq. yds., together with substantially built premises recently occupied by Messrs. W. Brown & Sons (contractors and builders, Salford) and their subtenants. The purchaser will have the option of buying the machinery, plant and fixtures on the premises within seven days from date of sale. The land and premises are conveniently situated, and are opposite to the principal entrance of and in close proximity to the most central portion of the Manchester Ship Canal and its docks. Further particulars from the Auctioneer, Cromwell-buildings, Blackfriars-street; from Messrs. Charles Dunderdale & Co., solicitors, Marsden-street; or Messrs. March, Clayton & Pearson, 22, Bath-street, Manchester. See also an advertisement.

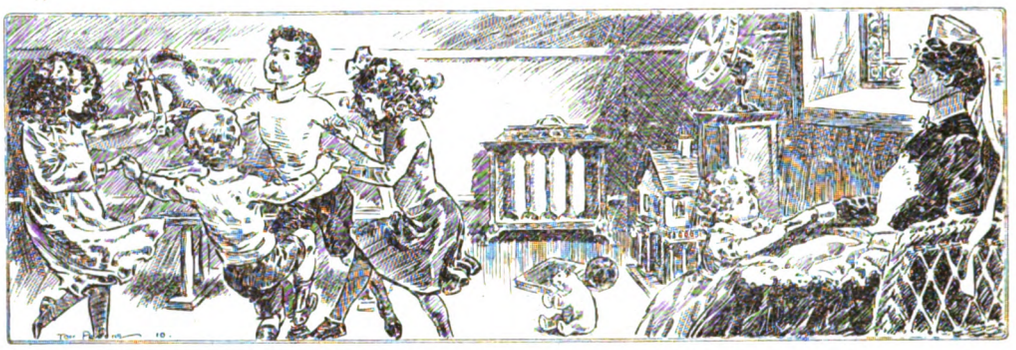
Plant for Sale.—Some second-hand electric motors are advertised for sale in another column.

Osram Lamps for Train Lighting.—The illustration herewith shows osram lamps in use for train lighting on the Waterloo & City tube railway. The general result of the lighting on this railway is undoubtedly remarkably good, and it is interesting to note that a lesser number of points per car are used than on any other of the tube railways in London. While these lines, speaking generally, arrange the lamps along the roof of the car on each side immediately above the heads of the passengers, the Waterloo & City line run their lights from the centre of the roof. 26 fittings are utilised for each four-car train, each of the larger cars taking seven 55 watt osram lamps, and the smaller cars six 55 watt osrams, each independently arranged in opalite globes, which permit of a considerable volume of light being thrown on the white enamelled roof, which by its peculiar shape acts as an efficient reflector. The lamps are burned four in series, and have now been installed a complete year. We learn that there have been very few failures, and that many of the original lamps are still in use. There is of necessity considerable vibration on this line, which does not appear to have had any adverse effect on the lamps.



TRAIN LIGHTING BY OSRAM LAMPS.

Illustrated Publicity Methods.—Last week we called attention to an illustrated poster that is being employed for publicity purposes by the Electric Supply Publicity committee, and accompanying this



ELECTRICITY PUBLICITY DESIGNS.

note are two typical illustrations of the methods adopted by the committee to advance the same interests. It will be agreed that they are very effective and display the merits of electric lighting,

ELECTRICITY PUBLICITY DESIGNS.

electric heating and ventilation by means of electric fans in a very attractive manner.

Loose Leaf Books for Engineers.—Messrs. John Walker & Co., Farringdon House, Warwick-lane, London, E.C., are placing on the market, through the book-selling and stationery trades, a series of loose leaf books for engineers, which contain a number of tables and data of service for everyday reference. The tables have been selected and prepared by Mr. Norman R. Corke, A.M.I.E.E. The loose leaf books are published in a variety of bindings and refils of the ruled paper sheets, faint ruled sheets, plain sheets or tables can be obtained.

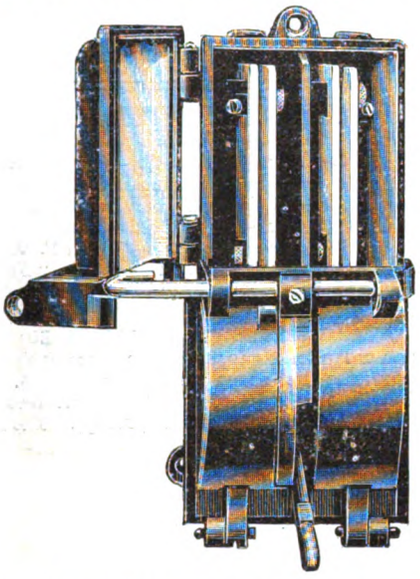
CATALOGUES, &c.

CHLORIDE ACCUMULATORS.—The latest publication from the Chloride Electrical Storage Co. is a complete illustrated price list of all their accumulator products. Practically every type of cell manufactured by the company is tabulated, prices and full details being given of its capacity, weight and size. The range of batteries is of the fullest possible description, extending from the smallest portable accumulators to the largest heavy-weight central station cells.

ELECTRIC FANS.—The Electrical Co. are issuing a leaflet describing their 1910 season electric fans. These are of the usual porthole, wall, bracket and ceiling patterns.

Digitized by Google

IRONCLAD SWITCHES.—Messrs. H. O. Farrell & Co., Moss Side, Manchester, send us a leaflet of their "Hof" combined ironclad switch and fuse. This is made in double-pole pattern in 20, 30, 50, 75 and 100-ampere sizes, and is suitable for pressures from 250 to



500 volts. The covers of the switch and fuse are interlocking, and the fuses cannot be inspected or removed until the switch is off. The adjoining illustration shows the general construction.

BANKRUPTCIES, LIQUIDATIONS, &c.

The examination of Wm. Chalmers, electrical engineer, 142, Bath-street, Glasgow, will take place at County-buildings, Glasgow, on June 30.

The trustees (Mr. J. H. Haley, 29, Tyrrel-street, Bradford, and Mr. R. A. Vinter, King's-arcade, Market-street, Bradford) in the bankruptcy of Arnold Roberts, electrical engineer, 21, North-parade, Bradford, have been released.

Prockter & Kenyon (Ltd.) went into voluntary liquidation on 16th inst. Mr. T. Walton, 36, Spring-gardens, Manchester, was appointed liquidator, and is also receiver for the debenture holders.

Adjudication Annulled.—The adjudication of Geo. Huntingdon, electrician (trading with Wm. Hy. Lloyd Watson as Watson & Huntingdon), 83, Battersea-rise, S.W., and Dering-street, Bond-street, W., London, has been annulled, it appearing to the Court that all the debts have been paid in full.

Winding-up Petition.—A petition for the winding-up of the North Western Electricity & Power Gas Co. was presented on June 14, and will be heard on June 29 at the Court House, Quay-street, Manchester.

Bankruptcy Petition.—A petition against Frank Sheppard, electrician, 4, Haslett-road, Kensington, London, will be heard on June 30 at Bankruptcy-buildings, Carey-street, London, W.C.

COMPANIES' MEETINGS AND REPORTS.

India Rubber, Gutta Percha & Telegraph Works Co. (Ltd.)

The half-yearly meeting was held on Tuesday, Major LEONARD DARWIN presiding.

The SECRETARY (Mr. A. P. Crouch) read the notice convening the meeting.

The CHAIRMAN said that the business of the meeting was to ask the shareholders' sanction to the payment of an interim dividend. Since he last addressed them in December the board had been passing through a time of some anxiety on account of the instability of the markets for raw material. He did not wish to refer to the rubber market at any length, as his remarks would run the risk of being misconstrued. He should limit himself to saying that while they, in common with all who were engaged in the rubber trade, were greatly inconvenienced by the uncertainty of the market, yet they welcomed the development of raw rubber production because they considered it would eventually be of good service to them. Rubber stood at a high price, gutta percha was expensive, cotton had been uncertain and copper was gradually dwindling in price. Their turnover showed a considerable advance over last year. As the turnover he referred to was that of the money received or owing to the company in trading, a certain amount of this increase was due to the advances in the selling price which they had made during the last nine months. The demand generally for the company's tyres was increasing, and they were fairly well employed in the submarine and electrical departments. In view of the increased value of the stocks the company had to hold, and an increase in the amounts outstanding in their trading accounts, as well as certain extensions, the board thought it desirable to offer for subscription the balance of the preference shares remaining unissued. The subscribers to this issue, under the terms of it, did not receive any half-yearly dividend on this occasion; their first half-yearly dividend fell due on Jan. 1, 1911. He then moved that a distribution of 5s. per share, less tax, be made to the holders of preference shares, and the payment of an interim dividend of 5s. per share, tax free, to the holders of ordinary shares.

Col. A. WESTON JARVIS seconded the resolution, which was unanimously agreed to, and the proceedings terminated.

ANGLO-PORTUGUESE TELEPHONE CO. (LTD.)—At the meeting last week the chairman (Mr. H. Allen) said that between 1904 and 1909 their gross income had increased from £25,962 to £49,489, and gross profit had grown from £10,796 to £20,767, and net profit from £8,360 to £16,571. Half a dozen years ago they were declaring a dividend of 3 per cent. on a capital of £51,000, and now, for the third year in succession, they were paying a dividend of 8 per cent. on £100,000. The event of the year had been the inspection of their telephone system in Lisbon and Oporto by Mr. Frank Gill, chief engineer of the National Telephone Co. As anticipated, Mr. Gill had not much fault to find with what they had done; nevertheless, his visit had had an excellent effect in still further increasing te efficiency and economy of their working.

BRITISH ELECTRIC TRACTION CO. (LTD.)—At the meeting on Friday last the chairman (Mr. E. Garcke) said that the net profit was but little better than in the preceding year, but the indications of improvement in the future were distinctly better. They had added £41,780 to reserve and the total reserve on March 31 last amounted to £633,000 (against £602,000 in 1909), in addition to special reserves and about £13,000 written off. As to their investments, the proportion which did not earn any return during the year was less by £342,000 than in 1909, and the return on the whole of the investments was 2·63 per cent., compared with 2½ per cent. In regard to the "fair fare" system, which consisted in dividing the routes into short sections and charging a fare according to the number of sections travelled, they had increased the facilities for travel, and by offering inducements to passengers to travel longer distances with only a proportionate increase of fare they hoped to make more money. The company was interested in nearly 400 route-miles of tramways and light railway, which served upwards of 100 different towns and districts. Since the beginning of the year the traffic receipts had shown a marked improvement. It was not possible to make a definite statement yet as to whether that improvement was entirely the result of the "fair fare" system or whether it was due to better weather conditions and improved trade.

CHADBURN'S (SHIP) TELEGRAPH CO. (LTD.)—For the year ended March 31, the balance at credit of profit and loss account was £12,614.2s.6d, less managing director's remuneration, directors' expenses and depreciation (£4,058. 12s.). With balance from last year (£1,618) the total was £10,173. 10s. 6d. Deducting the dividend at the rate of £6 per cent. per annum on the preference shares and interim dividend of £6 per cent. per annum on the ordinary stock, the balance was £4,773. 10s. 6d., out of which it is proposed to pay a dividend on the ordinary shares of £10 per cent. per annum (less tax) for the half-year ended March 31, making, with the interim dividend already paid, a dividend of £8 per cent. per annum for the 12 months, carrying forward £1,773. 10s. 6d.

DIESEL ENGINE CO. (LTD.)—Mr. G. C. Ellis stated at the meeting last week that the results of the year's working did not compare favourably with those of the previous year, but the directors were not discouraged because they saw a very considerable chance of good business in the future, the set-back being entirely due to general depression.

GLOBE TELEGRAPH & TRUST CO. (LTD.)—The 37th annual meeting was held on Tuesday, under the presidency of the Marquis of Tweeddale, K.T., who said that the accounts would, he believed, be considered very satisfactory. It was the best report the directors had ever submitted. The receipts for the year to the end of May last, after deducting expenses, amounted to £209,117, as against £207,347 the previous year. The three usual interim quarterly dividends had already been paid to both the ordinary and preferential shareholders. These together absorbed £131,085, and the directors now recommended a final dividend of 5s. 9d. per share on the ordinary shares (making 5⅞ per cent. a year against 5¾ per cent.) and 3s. per share on the preference shares, absorbing £77,656, leaving £27,681 to be carried forward. They were, therefore, besides paying 3d. per share more as ordinary dividend, carrying nearly £400 more forward. This was mainly due to the increased dividend on the Telegraph Construction & Maintenance Co.'s shares, which had reverted to 17½ per cent. He was glad to be able to state that the value of their securities again showed a very large increase over their original cost. He then moved the adoption of the report and accounts and the payment of the dividends set out therein.

Sir JAMES PENDER, Bart., seconded the motion, which was carried unanimously. The re-election of the retiring director and auditors, and a vote of thanks to the chairman, terminated the proceedings.

GREENWOOD & BATLEY (LTD.)—After providing for interest on debentures and management expenses, making provision for doubtful debts, and writing off £2,958. 17s. 9d. in respect of final adjustment of various accounts brought forward from previous years, the profit for the year ended March 31 was £10,173. 0s. 10d., making, with £2,066. 8s. 5d. brought forward, £12,239. 9s. 3d. The directors have written off £3,000 for depreciation, and they recommend that a dividend for the year be declared at the rate of 7 per cent. per annum on the cumulative pre-

Digitized by Google

ference share capital, absorbing £7,027. 17s. 3d., and leaving £2,211. 12s. to be carried forward. Major-General Edward Micklem has been elected chairman of the board; Mr. H. Greenwood has relinquished his position as a managing director, retaining his seat on the board; and Mr. S. T. Butler and Mr. Thos. Greenwood have been appointed managing directors.

MARCONI'S WIRELESS TELEGRAPH CO. (LTD.)—The report of the directors for the year ended Dec. 31, 1909, states that during the year the company suffered a serious set back by the disastrous fire which destroyed the Glace Bay station, in Canada, on the eve of its completion. But for this misfortune a considerable revenue should have been derived from the trans-Atlantic service. No time was lost in the reconstruction of the station, and advantage was taken of experience, and improvements which it is confidently anticipated will fully compensate in the future for the disappointment and delay. Notwithstanding the serious effect on the revenue occasioned by the fire, the profit for the past year was £11,432. 10s. 7d. Arrangements are being made which should enable the Canadian company to repay, at an early date, if not the whole, at least a large proportion, of its indebtedness (£144,279. 7s. 11d.) to the company.

Throughout the past year there was experienced a continuously and rapidly increasing demand for wireless telegraphy. A large number of contracts have been accepted by the company, but not having been completed by the end of the year no portion of the profits which should be derived therefrom figure in the accounts. A marked improvement in the business done by the associated companies has also been experienced, several of which are now commencing to show profits, and with the ever-increasing appreciation of the Marconi system the directors look with growing confidence to their large shareholding in these companies. The French and Belgian companies have declared dividends for the past year at the rates of 5 and 10 per cent. respectively. The directors recommend payment of the cumulative 7 per cent. dividend on the preference shares to June 30, 1909. The expansion of the business during the current year should enable them to make a further announcement in this direction so soon as the accounts for the first six months have been made up.

Although the report deals only with the accounts and progress of business to the end of the year 1909, the directors take the opportunity of officially informing the shareholders that the trans-Atlantic stations have been re-opened, and a regular and satisfactory service is being conducted. Other important developments of the business are in course of negotiation. In January last Mr. H. Jameson Davis resigned his directorship, and since the last meeting Mr. Godfrey C. Isaacs and Mr. Alfonso Marconi have been elected to seats on the board.

NATIONAL ELECTRIC CONSTRUCTION CO. (LTD.)—Mr. L. B. Schlesinger, who presided at the meeting last week, said the depression in the electrical industry had been even more acute than in previous years, and finance in connection with it, particularly in this country, had been practically impossible. However, the undertakings in which the company was substantially interested were progressing. They were now engaged on the finance of a light railway scheme in England, and the progress made so far encouraged the feeling that they would be successful in completing it.

R. WAYGOOD & CO. (LTD.)—At the meeting last week the chairman (Mr. H. C. Walker) said that the past year had been beset with much anxiety for the directors in consequence of unprecedented competition and exceptionally low prices. By careful management and attention to details they had been able to maintain the dividend of 6 per cent. They had been successful in securing the most important contracts which had been let this year, including the new post office. That contract was for 12 electric lifts, some of them to raise 2 tons at a speed of 200 ft. per minute. Those were the largest electric lifts which had hitherto been made in this country to work from three-phase current, and their installation involved very special arrangements, both in design and manufacture. They were also successful in obtaining the contract for the lifts for the Royal Liver Friendly Society building in Liverpool, which was to be equipped with 15 of their high-speed electric passenger lifts, some of them working at 400 ft. per minute. The contract was awarded to them on account of economy which they were able to offer in consequence of special design, and when finished the equipment of lifts would be second to none in the United Kingdom. They had also secured the order from Messrs. Harland & Wolff to fit the new White Star liners "Olympic" and "Titanic" with 16 lifts, including eight of their special electric passenger lifts. They had now fitted over 50 ships with their lifts, quite apart from the special work done in that direction for the Admiralty, for whom they had fitted 39 electric lifts on battleships and cruisers.

J. G. WHITE & CO. (LTD.)—The directors' report for the year ended Feb. 28 states that the results of the business have been satisfactory, with a net profit on the year's trading of £64,801. 16s. 1d., the highest earned in any year since the formation of the company. The company, which is carrying out important works in Brazil, Argentina and other points abroad, has more work actually in hand and uncompleted than at any time during the past three years, and general conditions have improved so that considerable additional work is expected. The return of interest and dividends on investments during the year was equal to 6·2 per cent. on the amount of the valuation. The reserve fund having now reached £100,000, the directors consider that the "purchase of business" account should be written off, and they are therefore recommending its reduction this year by £32,975. 1s. 10d., leaving £15,000, which they hope to be able to write off next year. The directors are pleased to be able to recommend an increase of the total dividend rate on both classes of shares to 10 per cent. The balance to credit of profit and loss, after bringing in £15,480. 6s. from previous account, deducting interim dividend paid on the preferred shares on Jan. 1, and making provision for percentages due to directors and staff, is £67,879. 9s. 6d. The directors recommend payment of a dividend (tax free) at the rate of 6 per cent. per annum on the cumulative preferred shares for the half-year to Feb. 28 (£4,500), a dividend (tax free) at the rate of 6 per cent. per annum on the ordinary shares for the year (£3,000), and payment of an additional 4 per cent. (tax free) on the preferred and ordinary share capital (making 10 per cent. on all shares for the year) (£8,000), and that £32,975 be applied in reduction of "purchase of business" account, leaving £19,404. 7s. 8d. to be carried forward.

NEW COMPANIES.

FREDK. JONES & CO. (LTD.) (110,247.)—Reg. June 17, capital £15,000 in £1 shares, to carry on the business of manufacturers of silicate cotton or slag wool, fibrous plastering, building blocks and insulating materials, non-conducting covering compositions and materials, boiler disincrustants, &c., and to adopt agreements (1) with F. M. H. Jones for the acquisition of the businesses carried on by him as "Fredk. Jones & Co," and (2) with J. Christie. Private company. Reg. office, Perrin-street, Kentish Town, London, N.W.

CALCUTTA ELECTRIC SUPPLY CORPN. (LTD.)—The number of units delivered to consumers during the four weeks ended May 27 were 786,249, compared with 693,479 units in the corresponding four weeks of 1909.

COMPANIES TO BE STRUCK OFF THE REGISTER.—The following will be struck off the Register of Joint Stock Companies, unless cause to the contrary is given before Sept. 21:—

Electric Vehicles Development Co., Foreign Chemical & Electrolytic Synd., Newark Electric Supply Co., Ozone Purification Co., Railway & Tramway Concessions Synd., Selneff Batteries, Ystradgynlais Electric Lighting Co.

EASTERN TELEGRAPH CO. (LTD.)—This company announce payment on July 15 of dividend at the rate of 3½ per cent. per annum (less tax) on the preference stock for the quarter ending June 30, and a first quarterly interim dividend of 1¼ per cent. on the ordinary stock (tax free) in respect of profits for the year ending Dec. 31, 1910. The transfer books of the ordinary stock will be closed from 7th to 14th prox. inclusive.

EASTERN EXTENSION AUSTRALASIA & CHINA TELEGRAPH CO. (LTD.) The directors have declared an interim dividend for the quarter ended March 31 last of 2s. 6d. per share (tax free), payable on July 15. The share register will be closed from 7th to 14th prox. inclusive.

ELECTRIC LIGHT & POWER CO. OF COCHABAMBA.—During the week Messrs. E. Erlanger & Co. invited applications for the purchase at 98 per cent. of £300,000 of six per cent. Government guaranteed bonds of this company, which is now engaged in constructing an electric railway from Cochabamba to Quillacollo (Bolivia), a distance of 15 km. (over 9 miles), and the Government have arranged with the company for the construction of a second electric railway from Quillacollo to Arani (30 km., or 18½ miles), with branches to Caraza and Vinto, and for the erection of stations for the generation and supply of electric power.

NEW YORK TELEPHONE CO.—The net earnings for 1909 were $10,571,978, and after deducting the interest charges and dividends ($5,633,329), the balance was $3,957,419, increasing the surplus brought forward to $13,591,711.

SHAWINIGAN WATER & POWER CO.—A dividend of 1 per cent. for the year ending June 30 has been declared.

STOCK EXCHANGE NOTICES.—The Stock Exchange committee have appointed July 7 a special settling day in scrip (fully paid) for £250,000 5 per cent. debenture stock of the *Metropolitan Electric Tramways (Ltd.)* and scrip (fully paid) for £250,000 5 per cent. first mortgage debentures of the *Vera Cruz Electric Light, Power & Traction (Ltd.)*, and have granted official quotations in both cases. The committee have been asked to grant quotations to a further issue of 100,000 10 per cent. £3 preference shares and £225,000 4 per cent. mortgage debenture stock of the *British Westinghouse Electric & Mfg. Co. (Ltd.)*; $5,000,000 capital stock of the *Manila Electric Railroad & Lighting Corpn. (Ltd.)*; and $600,800 additional 5 per cent. first mortgage 20-year gold bonds and $3,000,000 common stock of the *Northern Light, Power & Coal Co.*

WINNIPEG ELECTRIC RAILWAY CO.—The directors have declared a dividend of 10 per cent. for the year ended June 30.

Problems of Ventilation.

THERE is yet much to be done before a satisfactory solution of the problem of ventilation is brought about The ventilation of buildings by natural and artificial methods is still something of an experiment. The process in which the air near the ceiling or roof of a building is removed by induction is not adequate for universal application. It does not provide for what, in electrical parlance, may be called "heavy overloads." When a hall is filled beyond its normal seating capacity the ventilating arrangements fail utterly at the very time when some operating reserve in them is looked for.

The value and importance of the electric motor is universally admitted as a contributory factor to the solution of this knotty problem. At a rough estimate two-thirds of the modern large public buildings are electrically ventilated, and as a rule the results achieved are highly satisfactory. But these results have only been obtained by a study of the conditions of the particular building and the application of the electrically-driven plant to the desired end.

It must not be supposed that because the electric ventilating fan is such a simple and efficient air mover there is nothing else to be done than cut a hole in the wall of a building somewhere near the roof and set the fan going to secure adequate ventilation. We are familiar with an instance of a church where something like this was once done. The edifice was electrically lighted, and the organ was blown by a motor-driven kinetic blower, so that the introduction of a ventilating fan seemed a delightfully simple matter. In construction the church was high-roofed in the nave and chancel, but rather low-roofed in proportion at the aisles. A hole was cut in the wall at the top end of one of these aisles immediately facing the Lady chapel, which was formed by an abutment on the north side of the church. Into this hole a propeller type fan was fixed, but in this position it failed to ventilate the church. After careful consideration of the matter it was apparent that the only place for the fan was in the organ loft, which was built over the south aisle near the chancel, and gave on to the body of the church through a nest of pipes in an archway immediately overlooking the choir stalls, and high up in the roof. The original hole made for the fan was bricked up and, with the fan in its new position, the ventilation of the church was all that could be desired. The fan can be speeded up so as to remove more air when the congregation is above normal in its attendance.

It is not always possible to adopt cut and try methods in dealing with the ventilation of a building, but the most satisfactory results are usually obtained when some kind of test is first applied to the initial position of the motor and fan.

The Electric Driving of Printing Machinery.

THERE is perhaps no direction in which the electric motor so well holds its own as in the operation of printing machinery. The small space which it takes up, the ease with which it can be controlled, and the possibility of its being left in charge of comparatively unskilled labour, all mark it out for the work. In the application of the electric drive to printing machinery some interesting problems arise—problems which lead to solutions none the less interesting and ingenious. These problems fall naturally into two classes, the methods of driving and the methods of control, and as Electromotors Limited are a firm who have much experience, it will be perhaps expedient for us to give a summary of their views on both these subjects.

There are several methods in which printing machines may be driven by electric motor, namely, by coupling direct, belt driving, and spur gearing. The coupled direct arrangement is not much used in this country, as it is an expensive arrangement. The two principal methods therefore, are the spur gear drive and the belt drive. A belt-driven arrangement may be one in which the motor drives by belt on to the fast pulley of the printing machine only, or it may be provided with a broad pulley so as to drive on to the fast and loose pulley of the machine. The latter arrangement is shown in Fig. 2. In small printing works where only a few machines are used, and where it is necessary for everything to be as simple as possible this method has advantages, as when the motor is once started up the machine is operated by the striking lever in the ordinary way. Its chief disadvantages are the space taken up at the side of the machine and the fact that the motor is always running, driving the loose pulley, and using up a small amount of energy when the machine is not being run.

The belt-driven arrangement in which the machine is started and stopped by means of an electric starting switch—

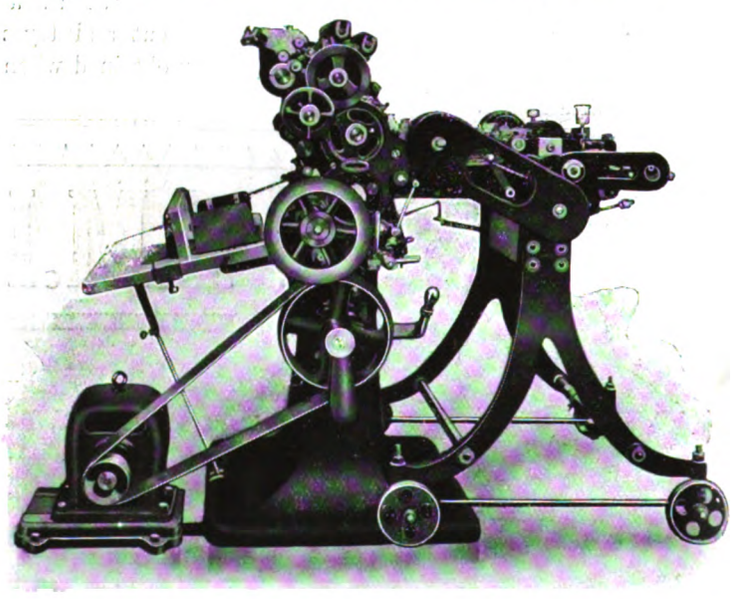

Fig. 1.—Harris Minor Press, Belt-driven by Motor.

Digitized by Google

that is to say, the belt runs on the fast pulley of the machine only, gets over the disadvantage of running the motor continually, and so wasting a little energy, but it necessitates a more robust and better quality of starting switch than is required with the fast and loose pulley arrangement.

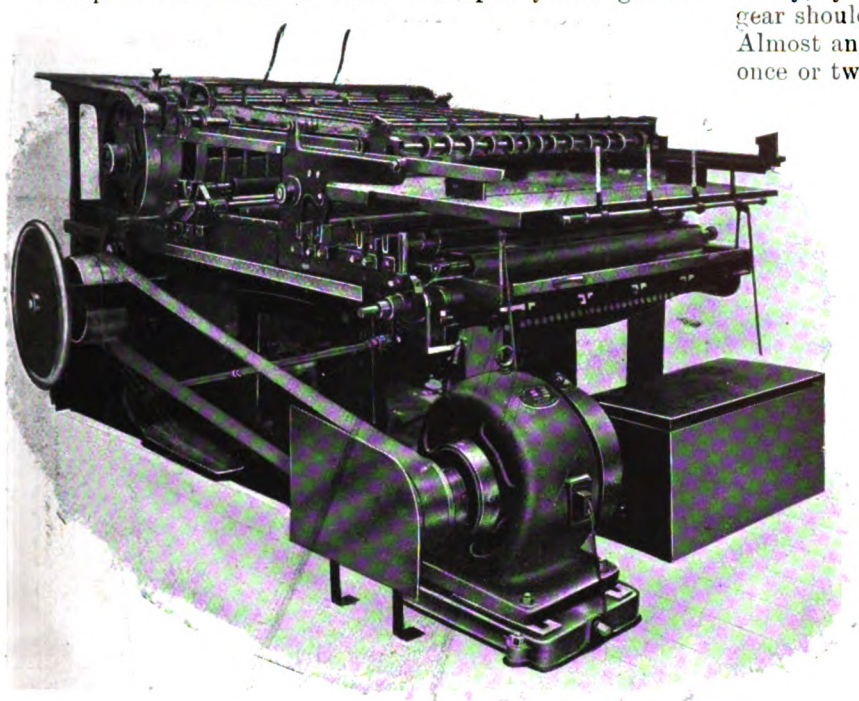

Fig. 2.—Furnival Two-revolution Press.

This is a point that is frequently overlooked by those who have not special experience in printing press equipments. Another advantage of this method is that it is possible to use larger pulleys than are usually fitted with fast and loose pulley arrangements, thus ensuring a more satisfactory drive.

Economy of space is generally an important consideration in a printing office, and accessibility to the working parts of any machine is a consideration in every works. These considerations sometimes make it necessary to fit the motor at the back of the machine, and as close up as possible. This often results in a very short length of belt.

A short drive, however can be made quite satisfactory if the arrangements are carefully designed, as is shown in Fig. 3. In this illustration it will be seen that the motor is practically close up to the litho press, the belt passing under a jockey pulley, the tension on the belt being controlled by means of an adjustable spring. With this arrangement the belt must be sufficiently flexible to bend easily in either direction. The spur-geared arrangement is an excellent method of driving and economises the space very considerably, but requires careful designing. The tooth form and ratios of gearing should be given considerable attention, and not only must the gears be properly meshed when standing, but the machine and motor must move together in unison so that they mesh together when running.

As a rule the driving arrangements receive more consideration than the switching details. Being a mechanical matter it is one which the printer can more fully enter into. When the press is started and stopped electrically, that is to say, by means of a switch, it is essential that the switchgear should be specially designed to stand the severe duty. Almost any standard switch may be used to start a motor once or twice a day, but to "inch" a machine round when 'making ready" is about as severe a duty as it is possible to imagine. When a machine operator wants to move his cylinder an inch or two, he does not pull the flywheel round if he has a switch close at hand. The result is that in printing operations the switches are used hundreds of times more frequently than with other classes of work. Obviously, the life of a switch depends not so much on the length of time it is in service, as on the number of times it is used, and as a switch on a printing press gets more use in a week than any other switch gets in a year, the depreciation is very rapid unless specially designed for the work. The motors also feel the effects of unsuitable switching apparatus, excessive strains being thrown upon them if the starting resistance is cut out too rapidly.

In all well-arranged printing machine rooms a double-pole switch is placed in a convenient position for the layer-on. This is the only switch he handles, and is less trouble to operate than the ordinary brake lever. The starting switch proper is fixed at the back of the machine, and as soon as the layer-on closes his switch the starting resistance is automatically cut out slowly, and the machine is gradually accelerated. This system removes the disadvantages referred to above, as the make and break switch can be made very strong, whilst the motor is protected against sudden shock and overloads due to improper starting. A small switch alongside the starter acts as a speed regulator which permits of 20 different speeds being obtained

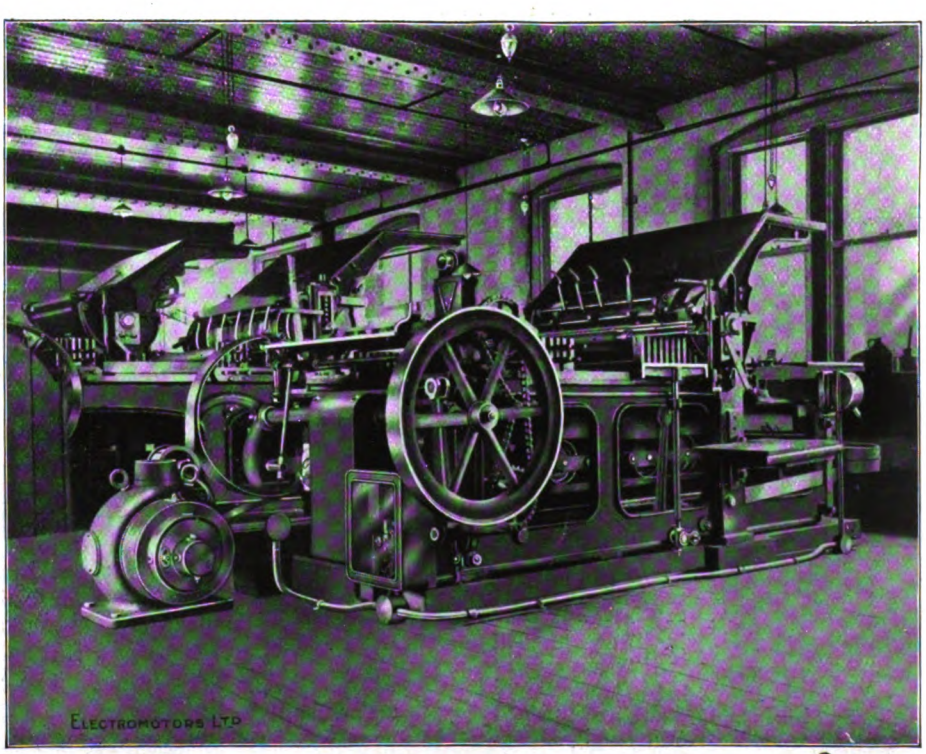

Fig. 3.—Electrically-driven Litho Press.

Digitized by Google

in the most economical manner. The main current does not pass through this regulator, but only the magnetising current, which is a very small fraction of the total. By this means the lowest speeds are as economical as the highest The regulator is provided with a removable handle, so that the speed can be set by the overseer and cannot be altered by the layer-on. The whole thing is very compact, occupying a space of only 7 in. square by 4 in. deep. This arrangement is a little more expensive in first cost than the plain manually operated starter, but it pays in the long run.

At the recent Printing Exhibition at the Agricultural Hall, Messrs. Electromotors (Ltd.) carried out the electrical equipment of several of the stands. There were some 10 or 12 motors on Messrs. Harrild & Sons' stand, arranged with the object of demonstrating the various methods of electrically driving printing machines and the adaptability for any class of machine. There were three flat-bed presses, a demy rapid cylinder, a double-demy two-colour and a double-demy single-colour. The first of these was running at the very high speed of 3,300 impressions per hour and was driven through an ordinary belt on to fast and loose pulleys. The two-colour had a motor bolted direct to the machine frame and driving through raw

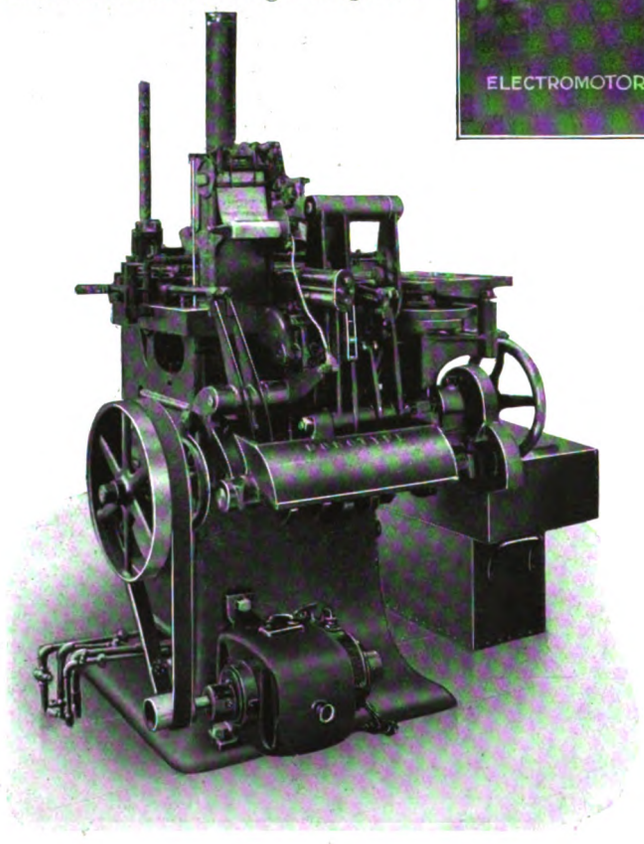

Fig. 4.—Monotype Casting Machine driven through a Short Belt by Specially Designed Motor.

hide pinion and spur gear. The starting and stopping of the machine was obtained through a small main switch within easy reach of the operator; this main switch simply controlled automatic starting gear, and it can be seen that with this system the operator wasted as little time as possible on the electrical equipment, and the control of the press was brought to perfection. Inching could be carried out with accuracy to about ¼ in.

The single-colour machine was equipped in the same way, and both these machines had small shunt regulators which enabled the motor speed to be varied 50 per cent., so that the machines may be run to the highest speed compatible

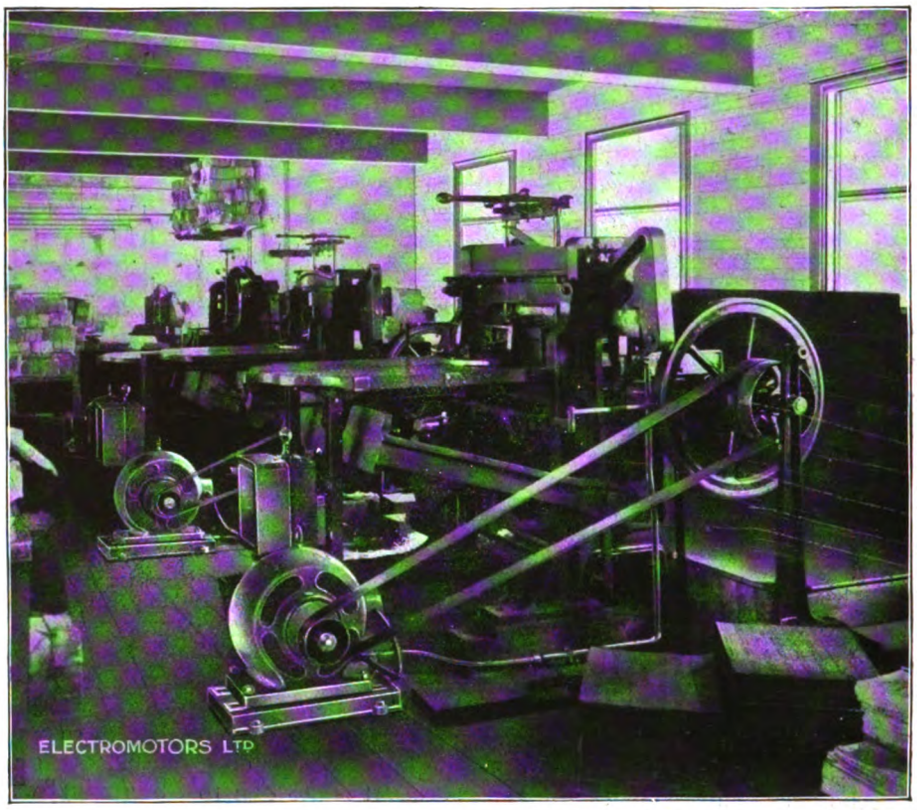

Fig. 5.—Belt-driven Printing Machinery.

with the work in hand. The other machines consisted of guillotines, saws, planers and block presses. Each one has its own individual motor and this exhibit might be looked upon as illustrating the most up-to-date electrical driving on the unit system, which was, without doubt, the most economical in running costs.

On Messrs. Crosland's stand a cutting machine operated direct by motor through fast and loose pulley, and a platen type of press, used chiefly for embossing, was motor driven, the motor being specially designed to take the heavy load which comes on at the impressions.

The drive on Messrs. Mann's stand was in contradistinction to Harrild's, as in this case a 10 H.P. motor drove on to an overhead line shaft from which the different types of litho presses and their new offset press were driven. The system has the advantage that the initial outlay is lower, but there are disadvantages to it, viz., increased running costs, no facility for obtaining variable speed except by step pulleys, and the countershaft and belting is all running if only a single press is in operation.

Messrs. Electromotors (Ltd.) also provided the equipments for the machines on Messrs. Lockett's stand. Two of their flat-bed presses were fitted with motors driving direct through gearing and bolted direct to the machine frame. The control gear on these machines was not automatic, but was of the latest type of hand operation starter which was, it is claimed, as perfect as is possible to obtain.

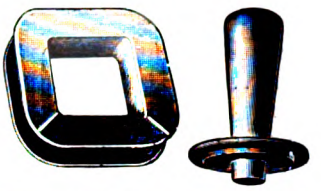
Insulators for Electric Furnaces, Tramways, &c.

Japanese Paper in Rolls and Tapes. Oil Varnished Linen, Silk and Paper, &c.



Insulating Material for Electrical Work. . .

PRESS-SPAHN is undoubtedly one of the most important insulating materials used in electrical engineering. Originally it was employed as a separator between the layers in the manufacture of cloth and silk, but nowadays it belongs to the most valuable materials used for insulating purposes. Its advantages are high insulating resistance, great mechanical strength and cheapness. In hot oil it will not split like costly mica and will keep for many years in temperatures of 80°C. to 100°C. The firm of H. Weidmann, Rapperswil (Switzerland), has taken an important and active share in the general introduction of press-spahn as an insulating material. This firm's product is especially prepared to meet the influences of damp air, the insulating qualities of press-spahn being largely dependent on the condition of its surface. The test results obtained in the Physikalisch-Technische Reichsanstalt, Charlottenburg, have proved that an alternating-current pressure of 3,000 volts is required to puncture a press-spahn sheet with a thickness of 0·25 mm. The size of ordinary sheets is 70 cm. by 90 cm., but other sizes are supplied on request. The thickness varies from 0·10 mm. to 15 mm., the specific gravity being about 1·25. Press-spahn is not only supplied in sheets, but also in endless rolls, the latter modification being more and more in demand ; its special, advantage is that it can be cut in any desired lengths, thereby reducing waste. These rolls of press-spahn are usually supplied in lengths of from 50 to 200 metres, according to the thickness of the material.

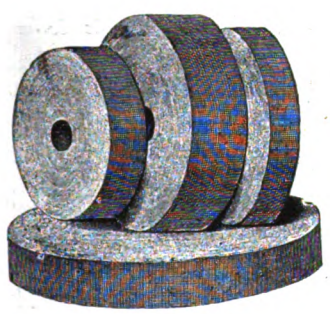


Fig. 1.

Fig. 2.

Fig. 3.

There is also an increasing demand for press-spahn in narrow strips rolled up like tape (Fig. 1). These strips are used for insulating armature slots, copper 'bus bars and strips, electric cables, &c. The width of these strips is made from 15 mm. to 500 mm., the thickness is from 0·10 mm. to 1 mm., and the length between 50 and 200 metres. Attention may also be drawn to varnished press-spahn, presspan with mica layers and oiled and paraffined press-spahn. Cheap substitutes are sometimes made under the name of press-spahn consisting of ordinary lacquered cardboard, but there is an enormous difference between the two. Lacquered cardboard may possess one advantage, and that is cheapness, but for electrical purposes it is very much inferior to press-spahn. To put on to the cardboard surface an extra layer of varnish is one way out of the difficulty, but it is such a cumbersome and expensive process that in the end the previous advantage in price is lost entirely.

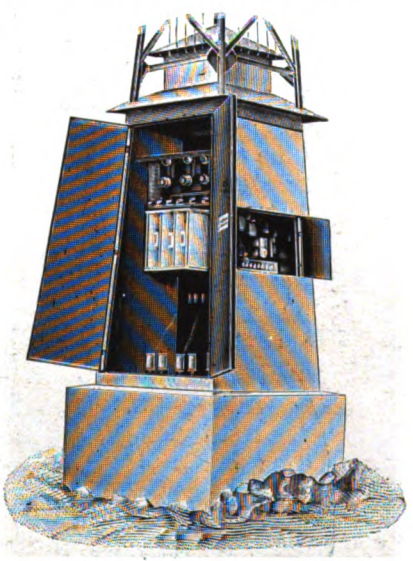

Fig. 4.

A special process has been adopted lately for making press-spahn tubes with and without asbestos and mica lining, also transformer cylinders and other insulating parts, such as slots, rings, discs and all manner of stamped articles, &c. We would finally point out that Messrs. Weidmann also manufacture all other electric insulating materials, such as mica parts, micanite in sheets and different patterns ; cornit, a high-tension material which will stand temperatures up to 300°C. and more, and which is recommended for high-tension parts (Fig. 2) ; vulcoasbestos and amianit are easily machined and formed, and are especially suitable for the construction of protective boxes and field bobbins without seams or metal corners, and made in one piece (Fig. 3) ; pyrostat, vitrit and pierrit are insulating materials for high temperatures of heat, which have been used as insulators in electric ovens.

The firm's list also includes other materials for the same class of work, such as lacquered materials and papers, Japan

Digitized by Google

silk, tissue and felt papers, the latter in rolls and strips, insulating beads, flexible insulating tubes for meters, apparatus and lamp manufacture, asbestos cement insulation in the shape of machined bases for apparatus, screens for high-tension fuses and lightning protective devices (Fig. 4), controller partitions, insulation for electric ovens and numerous other materials for various purposes.

Pumps for Sewage Work.

AMONG the firms who have devoted themselves to the design of pumps for sewage work may be mentioned Messrs. Hathorn, Davey & Co., of Leeds. For this purpose they make pumps in two well-known types, the three-throw horizontal and the centrifugal, both of these being specially designed for use with the electric motor. A standard type of three-throw pump is shown in Fig. 1, the discharge from which is nearly constant, while the apparatus is as practically efficient at varying heads and different rates of speed. It is claimed that there is comparatively little wear under trying conditions, such as gritty or impure water, and consequently the pumps have been largely adopted in mining work. Two pumps of this type, each designed to pump 115 gallons of water per minute to a vertical height of 600 ft. have been supplied to the Waihi Gold Mining Co., in New Zealand, while another set, approximately the same size, is now being built for the Leeds Corporation water supply.

Fig. 2 shows an illustration of this firm's high efficiency centrifugal pumps, similar to those used by the Leeds Corporation. These pumps are specially adapted for use where a small portion of the district lies considerably higher than the rest; for example, a part of the Leeds area is situated at too great an elevation for the water in the high level mains to reach it. A tank was therefore elevated 50 ft. above the level of the highest reservoir, and the pump, illustrated in Fig. 2, was installed to supply it. A float in the tank starts and stops the pump, which works quite automatically and only requires the occasional service of an attendant to oil and generally overlook it. These pumps, it is claimed, are specially suitable for direct coupling to electric motors, for they are both mechanically and hydrostatically balanced and the end thrust is eliminated. They have a very high efficiency over a considerable variation of speed, capacity and lift.

Electrical Progress.

IN this article we propose to call special attention to the progress which has been made during each preceding month by electrical manufacturers in their own special lines. This progress can be best gauged by reference to selections from their latest catalogues and price sheets, and we shall give short notes on the subject matter of such catalogues and lists as are sent to us, and which indicate either that new equipment has been designed or that modifications have been made in well-known apparatus.

Lighting Fittings.

LIGHTING AND HEATING FITTINGS FOR ELECTRIC VEHICLES.—In these days of Tube railways and motor cars attention must be paid to the proper design of the lighting arrangements. For in the former artificial lighting is always necessary, while in the latter the provision of a light inside the car greatly increases both its comfort and scope. A catalogue recently issued by *Messrs. Siemens Bros. Dynamo Works (Ltd.)* should, therefore, be welcome to every motor car owner. In it he will find illustrations and financial details of ceiling fittings and wall brackets, as well as more material things such as testing lamps, plug sockets and headlights. The comfort of the passenger in cold weather is not forgotten, and a very neat radiator has been designed for warming the car. With regard to price, it may be mentioned that a very good ceiling fitting can be obtained for 16s., rising to £1. 12s., while the wall brackets range about 16s. The radiator costs £1. 15s. complete.

"SUNLITE" AND "SUNLINE" REFLECTORS.—The needs of the shopkeeper who wishes to illuminate his windows in the best style should be met by a glance through a recent catalogue of the *Sun Electrical Co.* which gives details of "Sunlite" and "Sunline" reflectors. These are fitted with a heat resisting metal plate, while the lamps are carried on a swing arm allowing them to be easily get-at-able. Illustrations are also given of special fittings which have been designed for the lighting of pictures and other special positions. These reflectors are cheap, working out at 6s. 9d. per lamp length, and their use should quickly repay this small initial outlay owing to the increased light obtained.

LIGHTING ACCESSORIES.—In a pamphlet they have recently issued *Messrs. D. H. Bonnella & Son* go very fully into the question of wall sockets and plugs. These are made in a number of types and sizes in wood, porcelain, the prices ranging from 20s. to 72s. per dozen according to capacity. Combined switch and wall connections at 48s. per dozen and pressed switches at 40s. per dozen are also illustrated and described.

Motors.

MOTORS AND SWITCHGEAR.—One of the most complete motor catalogues which we remember to have seen has recently been issued by the *Electric Construction Co.* It is, in fact, a series of leaflets built up into one entity, each dealing with a particular type of motor. In this way we are taken rapidly through continuous-current motors of all sizes, through continuous-current generators, then alternating-current motors and switchgear. Finally we come to application, and here are shown the E.C.C. motor driving haulage gear. The catalogue ranges over too wide a field for us to go into it in any detail, but it will suffice to say that it should be in the hands of every electrical engineer and power user.

Electric Mine Pumping Installation for Handling Hot Water.

IN reopening the Ward shaft at Virginia City, Nev., a considerable flow of hot water was encountered, which for a time baffled the efforts of the workmen. The great depth of this shaft, 3,480 ft., and the high temperature of the water, 175 deg., made the work of pumping out the impounded quantity very difficult, but a temporary electric pumping outfit was finally successfully put into commission, and has since been supplanted by a permanent installation which easily handles the present continuous hot flow.

For emptying the mines, in the first place, a temporary motor-driven pump equipment was installed, by which compressed air-driven sinker pumps at the bottom of the shaft lifted the water to a centrifugal pump on the 2,330 ft. level. This, in turn, delivered to a vertical triplex pump on the 2,100 ft. level. The sinker pumps were supplied with compressed air from two 100 H.P. compound air compressors driven by 100 H.P. motors located on the surface. A three-stage centrifugal pump on the intermediate level was belted to a 50 H.P. induction motor, while a 100 H.P. induction motor drove a $6\frac{3}{4}$ in. by 8 in. vertical triplex pump at the uppermost pumping level.

This apparatus has since been replaced by the installation of the permanent pumping plant located in a pumping station 80 ft. long, 24 ft. wide and 20 ft. high, connected with the shaft 3,100 ft. below the surface. The permanent pumping equipment consists of a special slow-speed 800 H.P. induction motor, direct-connected to an express type duplex double-acting pump, operated at 195 revs. per min. The valves and other visible parts are of bronze, and the pump has a capacity of delivering 1,600 gallons per minute against a total head of 1,550 ft.

THE THOMSON ELECTRIC LAMP.

The Meter Reader's Lamp.

HANDSOME, DURABLE, NICKEL PLATED CASE. COMPACT, HANDY, AND PORTABLE IN SIZE.

The accumulator can easily be recharged, and will give from 4 to 6 hours' Brilliant and Continuous Light. For the past three years the THOMSON LAMP has been Used in all parts of the world, for all purposes.

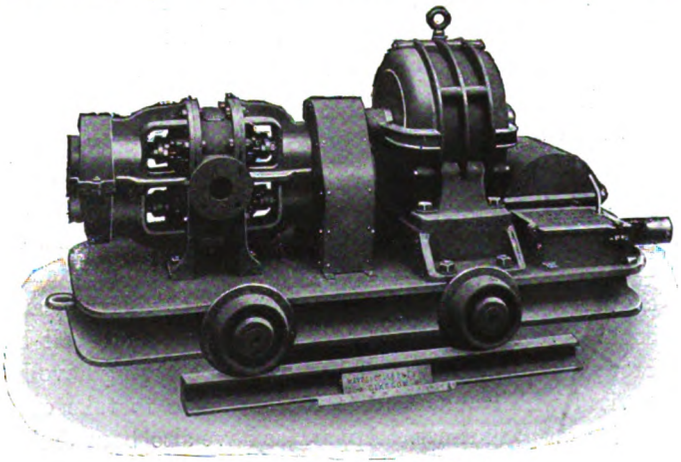
HALF SIZE.

Mavor & Coulson Pumps.

ONE of the great advantages of the electrically-driven pump is that it can be made portable with the greatest of ease. Given a source of energy supply, all is well. The combined pump and motor can be mounted on a trolley and moved over a wide radius of activity. The



Mavor & Coulson Portable Pump.

accompanying illustration shows a small electrically-driven portable drum pump manufactured by Messrs. Mavor & Coulson. They have supplied a large number of these sets for various pumps, which have proved entirely suitable for doing the work they are called upon to perform.

THE ELECTRICIAN INDUSTRIAL SUPPLEMENT.
ISSUED MONTHLY
"THE ELECTRICIAN"
Telegraphic Address: "ELECTRICIAN NEWSPAPER LONDON" Telephone No. 940 HOLBORN.

All communications should be addressed to the Editor, "The Electrician" Industrial Supplement, 1, 2 and 3, Salisbury Court, Fleet Street, London, E.C.

Copy for Text or Advertisement pages for next issue, publishing on **July 22nd, 1910,** *should reach the above address by Tuesday,* **July 12th, 1910.**

Manufacturers, Contractors, Central Station Engineers, and those interested in Electrical Industrial Developments are cordially invited to contribute original matter to the SUPPLEMENT, and when suitable this will be inserted as space permits.

Filing Case for "The Electrician" Industrial Supplement.

The INDUSTRIAL SUPPLEMENT is holed for filing, and we are distributing cases which will hold twelve issues. On request a case will be sent to Consulting, Manufacturing, or Contracting firms; to Chief or Resident Engineers of Electricity Supply, Traction or Power Stations; to any firm of Merchants or Agents; to Railway, Tramway, Dock, Harbour, or other companies interested in the applications of Electric Power, &c., to their undertakings; and to other large consumers of electrical energy, either at home, in the Colonies, or abroad.

A portion of each issue of the SUPPLEMENT is reserved for special circulation oversea.

Editorial.

The Off-Peak Load Problem.

In the early days of electricity supply, when the load was purely a lighting one, the whole design of the station depended on the amount of load which came on during the peak hours in the evening. These hours formed a small part of the total time of supply, the load itself being generally quite out of proportion to the demands on the station at other times. In fact, it was of an exceedingly peaky character. The condition imposed in this country, that the supply must be always available, made this state of things an additional disadvantage, so that stations were overburdened with capital expenditure upon which it was very hard to obtain an adequate return. At the present time, in many cases, these conditions have changed for the better. The increasing use of the electric motor has made an adequate day load possible, and in many cases the number of units supplied for power purposes exceed those supplied for lighting. But, even taking this into account, the load factor on many stations is much lower than it might be under better conditions, proper attention being paid in all cases to the necessity for a certain amount of spare plant being installed. How to improve these conditions has been the problem constantly before most station engineers in this country for some time past; fans, heating, cooking and domestic electrical apparatus, have all been brought into the arena, and systems of charging have been devised which almost force the consumer to take energy during off-peak times. Apparatus have also been designed for getting rid of the peak altogether, the Therol water heater being an example of one of the methods which have been devised for this purpose.

It is not surprising to find that in America, too, great efforts are being made towards obtaining a better off-peak load. Many American stations are not under the obligation to supply at all hours of the day, so that certain low-load losses, which are inevitable in this country, are avoided; but, on the other hand, it is not the desire of most station engineers to see their plant standing idle during a large part of the 24 hours, so that they naturally use their utmost endeavours to obtain an adequate day load, even in purely residential districts. Some interesting information on what had been done in this respect was given by Mr. H. G. Glass, of Pittsburg, in a Paper which he read a little while ago before the Iowa Electrical Association. The company to which he belongs supplies a number of large and small towns in Pennsylvania. A feature of every American city after nightfall is the electric light sign, and the company, therefore, fostered this method of advertising by supplying current for lighting these display signs at a flat rate. Metal filament lamps were used which were plainly stenciled, so that none, except those owned by the company, could be employed. Domestically an endeavour was made to obtain an introduction of electrically-driven apparatus by at first putting such things as irons and small motors on trial before actually requiring the consumers to buy them. The plant which proved most successful in this case was the flat iron, a type of apparatus by which much good was achieved in getting housewives to see the live possibilities of electrical working. The method employed was to issue a certificate for 8s. worth of energy, redeemable within 30 days of the date of issue by 8s. in cash in payment for the iron. The idea was to put the iron out on trial for 30 days and force the consumer to decide within that time whether he would cease to use the apparatus or pay the purchase price.

One of the last pieces of machinery to come under the influence of the electric motor is the sewing machine. In too many houses this is not electrically driven, and although we have never operated one ourselves, we cannot help thinking that the energy required to drive it must take the attention to a great extent from the work in hand. Mr. Glass pointed out that the plan set out above had assisted to popularise the use of sewing machine motors in his district, while electric toasters were brought to the notice of the public in much the same way. These latter apparatus, he found, gave even better revenue than irons, although their use has not become so general.

To obtain an adequate off-peak load it is self-evident that much careful canvassing must take place to induce consumers to recognise the advantages of electrical apparatus. Without wishing to decry our own country, it may be said that the American is an exceedingly good salesman, and recognises distinctly the points which must be brought before the prospective consumer. Mr. Glass has found that there are certain arguments that are very successful in bringing before the notice of the public the advantages of electrical apparatus. He advises that insistence should be placed on the small cost, the great safety and the cleanliness of electrical apparatus. That the less fire and accident risk should be pointed out, that mention should be made of the greater flexibility of the apparatus, while other points may be talked about are that there are no pipes to burst, that the operation is steady and that there is, consequently, less repair, less noise, power is always to hand, and less insurance money need be paid. There are no no-load

Osram and Tantalum Lamps.

LARGE STOCKS AND QUICK DELIVERIES.

Always holding large stocks of both Osram and Tantalum lamps for all usual voltages and candle-powers, we can supply your requirements **satisfactorily and promptly.** If you require lamps in a hurry, you can always depend on getting them here. If the circuit conditions are abnormal or the shape and size you require something special—a 'phone message or a wire will bring you the information required.

REDUCED PRICES OF TANTALUM LAMPS.

Don't forget that these lamps are now reduced in price, and we have laid in an extra supply to meet the resulting brisk demand. If you want your Tantalum lamps in a hurry, send along here.

The SUN ELECTRICAL CO., Ltd.,

Telegrams—"Secabilis London." Telephone—Gerrard 2291 and 2292.

losses, while better ventilation and lower temperature can be secured.

There has been a great discussion in this country lately as to whether central stations should undertake the selling or hiring of electrical apparatus. Much the same problem has apparently required to be tackled by American engineers, and, in the case of Mr. Glass's company, experience has taught them that the undertaking should at least be in a position to sell or hire motors; but whether it should actually do so depends entirely on local conditions. If the dealer handles a good type of motor and instals them at a reasonable profit, he should be assisted in his good work by the central station. But if there are cases where the central station must handle the sale of motors on account of the size of the main, terms of payment or the possibility of using the motor, it should be in a position to make the sale, and it should be able to inform the dealer that it has been done. With this point of view we agree. If the contractor can do the work he ought certainly to be allowed to do it; if he cannot, the electricity supply department must take the matter up.

Some Problems of Electric Headlights for Locomotives.

In this country we are not, as electrical engineers, excessively troubled with the problems of electric headlighting for locomotives. Our trunk lines are so hedged in, if not exactly with divinity, yet with something quite as substantial, as to be practically private rights of way that it is not necessary for the driver to see clearly whether cattle or humans have strayed on to the track. Further, the fact that the train runs on rigid rails and is subject to a complete system of signalling makes it unnecessary for the driver to see exactly where he is going.

In cases where electric lighting is used for the illumination of the trains it would certainly be advantageous to fit the locomotive headlights with, say, 16 c.p. lamps, but we protest against arc lamps being used for this purpose. These contentions are supported by some tests made recently by Prof. Benjamin, of Pendue University. In the United States the track is not so well guarded as in this country, and it is doubtless for this reason that electric searchlights have long been employed for throwing a concentrated beam along the track. Prof. Benjamin, however, finds, as might be expected, that the great intensity of the beam prevents signals and obstructions from being recognised. It may in this connection be pointed out that the driver is too near to the light for it to be of any help. The light from an approaching train was also blinding in its effect. These lights also made recognition of the signals difficult. It was found that the brilliancy of the beam from the electric headlight was so great as to produce by reflected light false signals from lanterns which had been extinguished. For example, in one test run, in which a green light had been extinguished, no light appeared up to a distance of 1,000 ft. At 600 ft. four of the 11 observers saw a green light in the extinguished lantern, which persisted for one observer up to 400 ft. The green lights suffered to an exceptional degree, but the red danger lights, fortunately, were less seriously affected. No reflections were observed when an oil headlight was used.

Automatic Solenoid Starters.

AN interesting series of automatic solenoid starters have been arranged by the British Westinghouse Co. for use in connection with "floating tank" equipments, that is, when the starter is required to stop the motor when the level of water rises to a certain amount and to start it

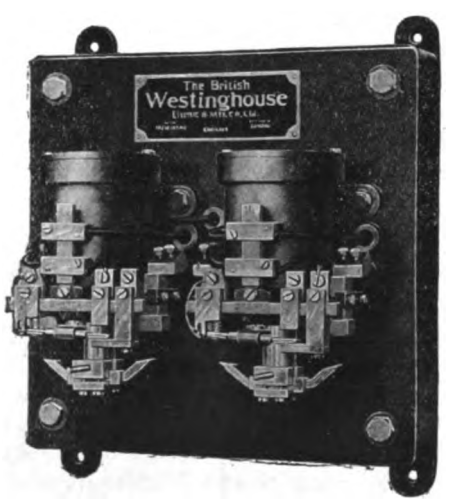

Fig. 1.—Westinghouse "El" Starter.

when the water level has fallen, and with hydraulic accumulators when it is desired to keep the motor running only as long as the accumulator is below a certain fixed level. In the latter case the float-switch is replaced by a suitable switch and air compressors. When it is desired to keep the air pressure within certain limits the float-switch is replaced by an air-governor switch. Or the same arrangement may be used for distant operation, that is, by closing the solenoid circuit by means of a small press button and so starting the motor up from a long distance and saving the cost of heavy cables between the point from which it is desired to start the motor and the motor.

The type "El" starter (Fig. 1) consists of either one, two or three solenoid operated switches, the number

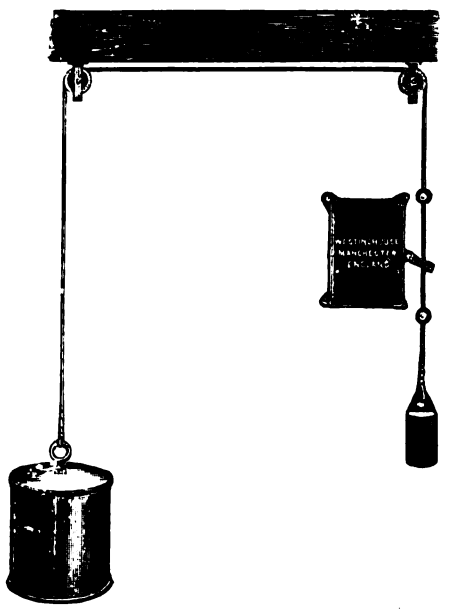

Fig. 2.—Diagram of the "El" Starter arranged for "Floating Tank" Work.

depending on the output of the motor, the coils of which are connected across the armature circuit. The main circuit of the motor is, in this case, made on the auxiliary switch. In the case of distant control with the El starter an extra solenoid switch would be required. This would be energised from the push button and would make the main circuit of the motor. The motor starts up, and as soon as its speed reaches a certain value, and therefore, of course, the E.M.F. across the coil increases to a certain amount, one of the solenoid switches will close, cutting a step of resistance out of circuit. The motor will then speed up and the voltage across the armature again increases, so cutting out another step of resistance. Another similar type of starter consists of a solenoid operated switch and a solenoid operated starter mounted on one cast-iron base. The solenoid of the starter operates a cam which, as it rises, allows the contact which cut resistance out of the armature circuit to close in the right order, so bringing the motor up to speed. This solenoid operates against an adjustable air dash-pot so that the time in which the motor starts can be regulated as desired. The auxiliary switch, that is, the float switch or air-governor switch, as the case may be, in this case makes the solenoid circuit of the main switch which closes and completes the circuit of the motor through the resistance, which in turn cuts out the armature resistance as explained above.

Both the above starters are insulated throughout with mica or porcelain, and are therefore absolutely fireproof. Being solenoid operated, they are, of course, fitted with a no-voltage release. The resistance is cut in the solenoid circuit of the switches when they have done their work, so that the energy consumed by them is cut down as low as possible. In the case of the type El equipment we would point out that only one solenoid is in circuit while the motor is running. The above starters can, when required, be fitted with sheet-iron covers.

Thornycroft Petrol-Paraffin Engines.

THE petrol-paraffin engines made by Messrs. Thornycroft are very instructive as examples of the application of internal combustion oil or petrol motors to a variety of duties. They are widely used for marine work in connection with both the main driving on launches and for auxiliary purposes such as lighting and pumping. The powers of the engines made range from 7½ B.H.P. to 350 B.H.P., and the sets include paraffin oil as well as petrol motors. In the Thornycroft system of using paraffin oil exclusively one lamp only is employed (irrespective of the number of cylinders) for heating the vaporiser, while an arrangement whereby, after running on petrol the few minutes necessary to heat the vaporiser, paraffin may be turned on and used without a vaporiser lamp is also supplied.

The ignition in all types of Thornycroft engine is by high-tension magneto, which has, contrary to the ideas formerly held, proved more satisfactory for sea work, as it renders starting much easier, and is more reliable than low tension, and at the same time avoids the complication of carrying a duplicate ignition of coil and battery. The lubrication system has been very much improved, and is now, it is claimed, as simple and as perfect as it is possible to design. The control is also a great advance on most arrangements hitherto produced, rendering the engine, it is said, as flexible as a steam plant. Most of the enignes are capable of running under ordinary working conditions between the very wide range of 300 to 1,100 revs. per min. for the paraffin sets, or 300 to 1,300 and 1,500 revs. per min. for the petrol sets. The reversing gears are of the latest types, in which have been embodied the results of experiment and information gained during many years of service under various conditions.

An example of the Thornycroft marine engine is the single-cylinder set, with a cylinder 4½ in. diameter, and a 6 in. stroke, developing 7½ B.H.P. on paraffin oil, with reversing gear and stern gear, comprising stern tube, shafting and a three-bladed Thornycroft bronze propeller. This type of engine has proved so successful in the West Coast Scotch fishing boats that it has paid for itself as a result of the increased earnings of the boat in one season of fishing. It is a very useful engine for either small launches or for auxiliary work.

A two-cylinder set of the same cylinder dimensions, developing 15 B.H.P. on paraffin oil, with reversing and stern gear, may also be mentioned. Large numbers of this type are in use for Government departments abroad, and it makes, it is claimed, a particularly serviceable equipment for ship's boats, where a good turn of speed and ability to work continuously with the minimum of attention are essential. A four-cylinder set (M/4 type) of the same cylinder dimensions, with reversing and stern gear, is also made. This is a particularly powerful and well-designed engine of most attractive appearance, developing 30 B.H.P. on paraffin oil. Attention may also be drawn to a four-cylinder (C/4 type) 6 in. by 8 in. set, developing 47 B.H.P. on paraffin oil, with reversing and stern gear. This engine has proved to be the most efficient of the various engines which have been fitted into Scotch East Coast drifters. The consumption of fuel is very low, the possibility of breakdown is remote, the ease of handling is such that a member of the ordinary drifter crew usually has charge of its running, and its power is equivalent (judged by speed under way) to motors of considerably greater listed power. Accessibility has been given particular attention so that the connecting rods and pistons may be removed without lifting the engine. Similar sets have been in service in various types of boats abroad (several in charge of natives) for many years, and are still regularly working. They are now being fitted to a number of large private yachts as auxiliaries. The same type of engine has been largely adopted for heavy vehicle propulsion, and it was one of this type which was fitted in the War Office tractor and obtained the sole prize of £750 granted by the War Office in March of last year. The exceptionally successful running of the engine and the general success of the vehicle itself have resulted in several repeat orders for tractors from the British War Office.

A four-cylinder 4 in. by 4½ in. petrol set (P/4 type) with reversing and stern gear has been designed to meet the demand for a lighter form of engine, suitable for pleasure or racing launches. The crank-case and other similar parts are of aluminium, and lightness has been attained without, it is claimed, in the least sacrificing the reliability which is a feature of all Thornycroft engines. The cost is very moderate, and the engine has already become very popular.

As regards stationary engines these are made in the single-cylinder type, 4½ in. by 6 in., the design being based generally on those for the corresponding marine sets, as the conditions of service (a constant load for long periods at a stretch) correspond to those for marine enignes. These engines can be used in connection with dynamo for electric lighting of ships, private houses and works or for generating power for tool driving. The output of the standard sets is about 4 kw., and this may be attained constantly without trouble. The set is shown with special bedplate with extension on which the dynamo is bolted. Another application of this motor is to the driving of centrifugal pumps for salvage purposes and water supply to country houses, &c. The bedplate of this plant is generally of the same form as in the electric lighting sets. The pump is coupled direct. Sets have been supplied for abroad with generator at one end and a pump at the other, with disconnecting gear to enable one or both to be run at the same time, or for the motor to drive machine tools by belt off the flywheel.

Messrs. Thornycroft are well known in launch work, and it may be interesting to give some details of one of their latest type. The boat is of the type of which Messrs.

Digitized by Google

Thornycroft have built large numbers. It is 30 ft. in length, built of teak throughout, and fitted with one of the two-cylinder 15 H.P. engines described above, using paraffin, and giving a speed of about 9½ miles per hour. It is capable of standing more than the ordinary amount of bad weather usually expected of such size craft, and it appears particularly suited for use all the year round off our own coasts. Such boats are in use by many of the large steamship lines as ship's boats, and also by pilot and Customs departments. The cost complete with all fittings is very moderate.

Electric Lifting Magnets.

IN recent years much has been done in the application of magnets to industrial work. Where iron of any kind has to be lifted or transported, it is obviously more economical to use a magnet to pick up the bars or scrap than an ordinary crane hook, for the arrangement is self loading and more material can be handled at a time. The holding capacity of such magnets depends largely on the materials which they have to handle, particularly, however, on the following points: The magnetic quality of the load; the temperature of the material to be lifted, which should not be above black heat; the shape of the load, and whether it consists of one solid piece or a number of small parts; and the manner in which the material to be lifted is stacked.

For general guidance it may be assumed that a magnet is capable of lifting a solid piece of steel, with machined

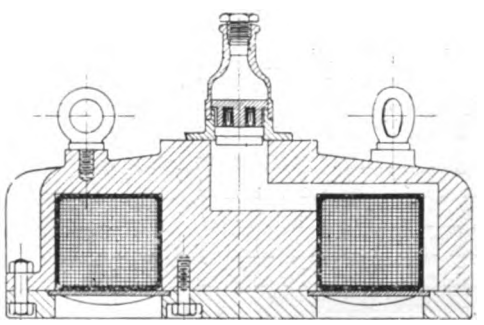

Fig. 1.—Section of Witton-Kramer Lifting Magnet.

surface, of not less diameter than the magnet itself, weighing approximately 15 times the weight of small magnets, 8 to 12 times the weight of magnets from 2 ft. to 3 ft. diameter, and five to six times the weight of magnets from 3 ft. to 5 ft. diameter. When dealing with materials such as sand-cast pig iron, or heavy scrap iron, the lifting capacity decreases considerably, depending entirely on the amount of material which is covered by the contact surface of the magnet. The larger the latter the greater the load attracted. With large diameter magnets, in addition to the first layer, further material is in some instances attracted by the centre pole, and thus a second, or even a third, layer is lifted. When handling metal plates the load depends greatly on the size of the plates, but up to six layers can be lifted, according to the thickness and the weight of each plate and the type of magnet. The quantity of loose or particularly small materials, such as punchings, stampings, drop forgings, nuts or bolts attracted by the magnet varies greatly, and is relatively small, in some cases only reaching up to about one-half the weight of the magnet. In order to increase the bulk of the material handled with each lift, a battery of two or more magnets should be used. In such cases the magnets are so suspended from a common bar or frame as to obtain the best results. This arrangement is advisable, particularly when handling long steel strips or sheets, as the overhang would possibly pull the load away from one large magnet.

Amongst other applications, magnets can be used with great advantage in connection with the iron balls or "crackers" employed for breaking up scrap castings in foundries, and attention may be drawn to the ready attachment and easy release of the ball, which can be obtained in all positions. Also, for pile-driving machines, the magnet can be used instead of the mechanical clutches usually employed, thus considerably increasing the operating speed. For submarine work, or submersion in water and other liquids, special watertight magnets are made. In fact, magnets can be applied with advantage wherever it is desired to dispense with mechanical clutches, clips, slings, chains or similar means for attaching materials to crane

Fig. 2.—Witton-Kramer Magnet Lifting Turnings.

hooks, where manual labour is too costly or unsatisfactory, and where hot plates, trays, hot castings, drop forgings and similar materials which cannot safely be touched by hand have to be transported. It has also been found, when unloading pig iron and scrap metal from railway trucks, considerable saving is effected by using magnets, as the small chips which are usually left in the truck when mechanical means are employed can be readily removed, it being only necessary to lower the magnet to within 1 in. or so of the bottom of the truck and sweep it over the surface when the remnants are gathered up.

The above-mentioned advantages and improvements are strongly emphasised by the very moderate working costs. For instance, a magnet of 24 in. diameter consumes only one-pennyworth of electricity for 25–30 lifts of one minute's duration each. A magnet of 48 in. diameter will do 8–10 lifts with one pennyworth of electricity. The maximum saving which owners can effect with a magnet such as is made by the Witton-Kramer Co. is, however, derived from

Digitized by Google

the fact that, besides the operator of the crane and a ground man (if the latter is at all necessary), all other manual labour at present required for the loading or unloading of the material can be entirely dispensed with. A saving in some cases amounting up to £25 per month per magnet can thus be obtained. The capital outlay for the magnet is therefore soon recovered.

Lifting magnets are only constructed for direct current, and where the supply is alternating current it is necessary to supply a motor-generator set or small accumulator battery, or an independent small steam or oil-driven set, to generate direct current for the magnets. In some cases it is also advisable to instal an additional accumulator battery to work in parallel with the dynamo, so that, should the latter break down for any reason whatsoever, the accumulator takes up the load. With magnet installations it is, of course, an essential point that the electrical wiring for same is executed in all its details in the most perfect way. We have made a special study of this, and are pleased to give our clients the benefit of our experience. Under such circumstances, there is no more chance of the load dropping than of the breaking of hoist ropes or chains. In special cases, however, if desired, mechanical safety appliances can be attached to any magnet.

The Witton-Kramer Electric Tool & Hoist Co., of Witton, Birmingham, have had a wide experience of this class of work, and some of the applications of their magnets are shown in the accompanying illustrations. The general construction of this magnet is as follows: The shell is of special high permeability magnet steel, with external ribs to assist the radiation of the heat generated in the magnet coil, and to add to the strength of the casting. To the top of the shell the necessary links, or eyebolts, are fixed for attaching the suspension chains.

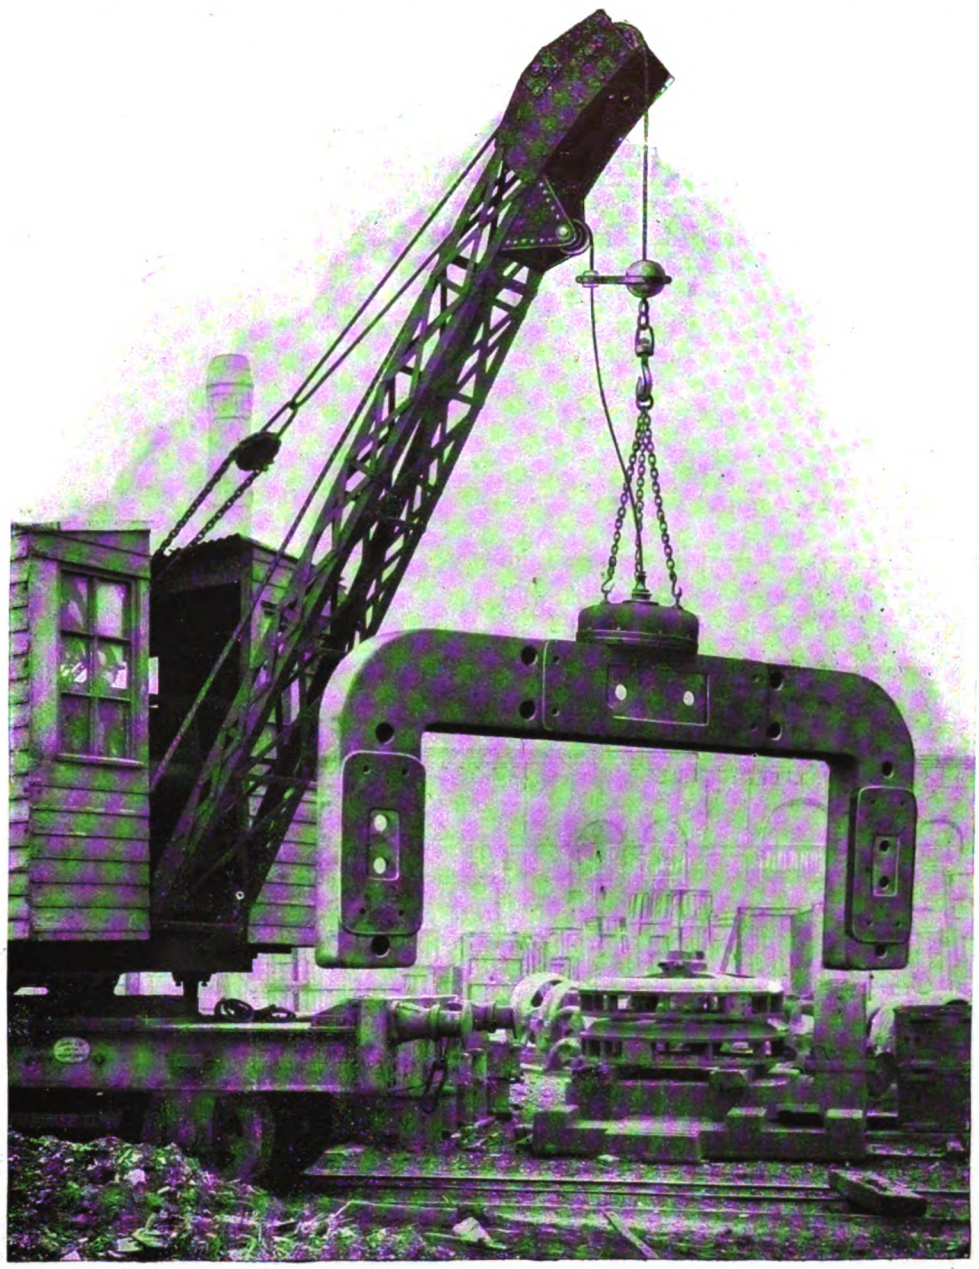

Fig. 3.—Witton-Kramer Magnet Applied to Heavy Crane Work.

The coil is wound of covered copper wire, insulated in the most up-to-date manner with the best and most suitable materials obtainable, and, when wound, undergoes the following treatment: The air and dampness unavoidably contained in the covering of the wire and the insulation in general is extracted by placing the coil into a vessel connected to a vacuum pump. Immediately the gauge glass shows that no more air or moisture is contained in the coil,

Digitized by Google

the vacuum chamber is filled from a high-pressure tank with a boiling asphalt compound. The coils are then kept under great pressure in this liquid at a temperature of approximately 200°F. The coil is then firmly fixed in the shell and compounded in position, and by these means is made entirely waterproof and impervious to moisture.

The coil is protected by means of a coil shield of manganese steel or extra hard phosphor bronze. The coil shield is held in position by means of the inner and outer pole shoes, which are of high permeability magnet steel, and can be easily removed by loosening the bolts which hold them. In some cases the joints are soldered.

The connection to the mains is obtained by means of a special iron-clad plug and socket, with suitable locking device. The leads are usually held by means of a split washer, and the whole plug and socket is filled with compound and entirely watertight. A cap is provided which fits over the plug when same is removed from the socket to prevent short-circuiting.

The controller is of the drum type, and, in some cases, oil-immersed. Non-inductive resistances are supplied to take up the induction of the coil when breaking the circuit. The wiring necessary for operating electric lifting magnets consists of a twin cable, specially made suitable for this class of work, leading over a system of pulleys provided with a counterweight to keep cable taut. In the case of jib cranes this cable is connected to the supply in the crane cabin, but for travelling cranes it is usual to instal two more trolley wires alongside the bridge, providing special collectors to collect the current.

The method of operating a magnet crane is similar to the working of any electric crane, with the addition only of an extra controller for exciting the magnet and releasing the load.

Pearn Colliery Pumps.

AN interesting sermon on the text of the application of electrically-driven pumps to colliery work could be preached by describing Messrs. Frank Pearn & Co's. activities in this direction. This agreeable task we have not time to do in anything like detail, but must confine ourselves to the description of one of two installations.

To make a start, the set of pumps shown in Fig. 1 have been supplied by this firm to the Rand Collieries at Johannesburg. They are of the three-throw ram type, and are driven by single reduction spur gearing direct by a B.T.-H. three-phase motor of 75 B.H.P. running at 480 revs. per min. This set is capable of delivering 10,000 gallons per hour against a head of 1,050 ft. The rams are 6¼ in. diameter by 9 in. stroke, and the crank shaft makes 60·66 revs. per min. The motor shaft carries a steel spur pinion, which gears with the cast-iron spur wheel, made in halves. The teeth of the latter are accurately cut. The crank shaft is a Siemens-Martin steel forging, and is of the combined sweep and overhung pattern; it is carried in three adjustable bearings. The construction of the connecting rods and pump barrels resembles those already described. The valve boxes are three in number, a suction and delivery chamber being embodied in single castings provided with separate doors for the valves. The rams are of cast-iron, working through gun-metal neck rings and cast-iron glands. The crossheads are cast on the rams, and are fitted with steel pins firmly secured, and work in slipper guides. The whole of the pumps, crank, and motor are mounted on a common bed-plate, which contains three castings bolted together. An alleviator by-pass valve and suction air vessel complete the installation. The illustration represents one of eleven pumps supplied to the mines in the Transvaal, six being at work at the Rand Collieries, four at the Cinderella Deep and one at Van Ryn gold mines.

Two interesting pumps, recently constructed for colliery work by Messrs. Frank Pearn & Co., Ltd., Manchester, are illustrated in Fig. 2, which represents one of two sets of horizontal three-throw ram pumps supplied to the Wallsend and Hebburn Coal Co., for Hebburn Colliery, near Newcastle-on-Tyne. The pumps are driven through cotton ropes by three-phase 40 cycles, 600-volt motors, supplied by the British Westinghouse Co., and when running at 375 revs. per min. consume 210 B.T.U. The combined efficiency of the motor and pump is about 75·6 per cent. Each set of pumps is capable of delivering 630 gallons per minute against a head of 1,100 ft. The rams are 12¼ in. in diameter by 18 in. stroke, and work at the very moderate

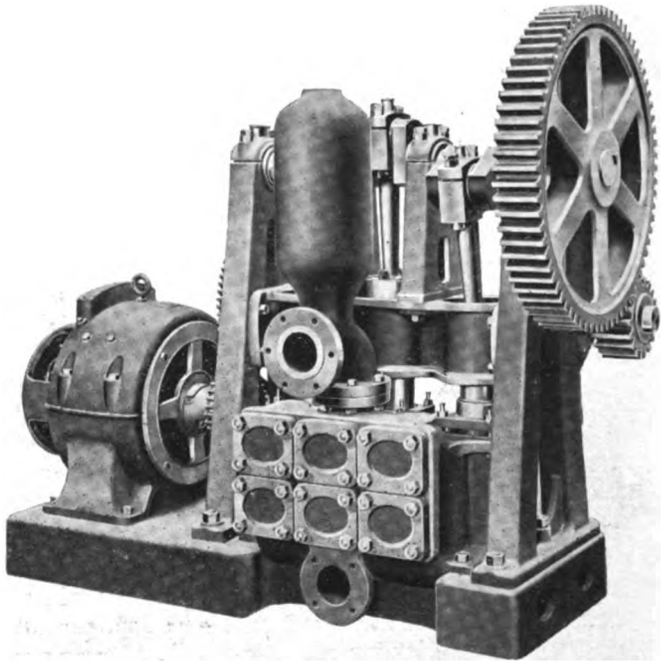

Fig. 1.—Pearn Three-throw Pump.

speed of 29 revs. per min. The advantage of slow-speed working is obvious. The minimum of attention is required, and no appreciable wear will take place for many years. The first motion shaft carries a rope pulley 13 ft. 3 in. diameter, with 13 grooves for 1¼ in. ropes, and is carried in adjustable gun-metal bearings. The crank shaft is driven from either side by means of single reduction gearing, the wheels being of cast steel, made in halves, with machine-cut teeth. The crank shaft is of forged Siemens-Martin steel of the sweep type, and is annealed after being rough turned. It is carried in four adjustable gun-metal bearings. The connecting rods are solid forgings, and have adjustable gun-metal bearings at each end. The pump barrels are similar; all flanges, as far as practicable, are fitted with bolts, no studs being used. The valve boxes for both the suction and delivery branches are all interchangeable. The rams are of solid gun-metal, and bolted to the crossheads. The stuffing boxes are fitted with loose gun-metal neck rings, and the glands are bushed with the same metal. The crossheads are of cast iron, with ample wearing surfaces, and working in slipper guides. The baseplate on which the pumps, crank, and intermediate shafts are mounted, is in three separate sections bolted

Digitized by Google

together. The pumps are fitted with a by-pass valve, delivery and suction air vessels, and Wipperman & Lewis air chargers.

An example of a verticle type equipment is the three-throw ram pump made by Messrs. Frank Pearn & Co., and driven by electric motor through double reduction gearing. The capacity of the pump is 9,600 gallons per hour against a head of 600 ft. The rams are 6 in. diameter and the stroke is 8 in. The pump barrels, valve chamber and vacuum are all formed in one exceptionally strong casting; which has a trough cast on to collect all leakage from the glands. The rams and crossheads are of cast iron, working through gun-metal neck rings and cast-iron glands; the crossheads, which are cast to the rams, are fitted with steel pins firmly secured, the crossheads working in guides. The ram guides are of the circular type of large area, and effectively take the wear off the rams, glands and packings. The guides are truly bored to fit the rams, thus permitting the rams to be readily removed. The guides are formed in one casting, which is bolted to the standards, thus ensuring rigidity. The crank shaft is turned out of a solid forging of specially selected steel, and annealed after being rough-turned, carried in four gun-metal adjustable bearings. The connecting rods are made from solid steel forgings, fitted with adjustable gun-metal bearings at each end, the ram ends working upon steel pins.

Fig. 2 shows a three-throw ram pump specially constructed to work under the following conditions, either verticle, horizontal, or on the incline, as may be required, during sinking

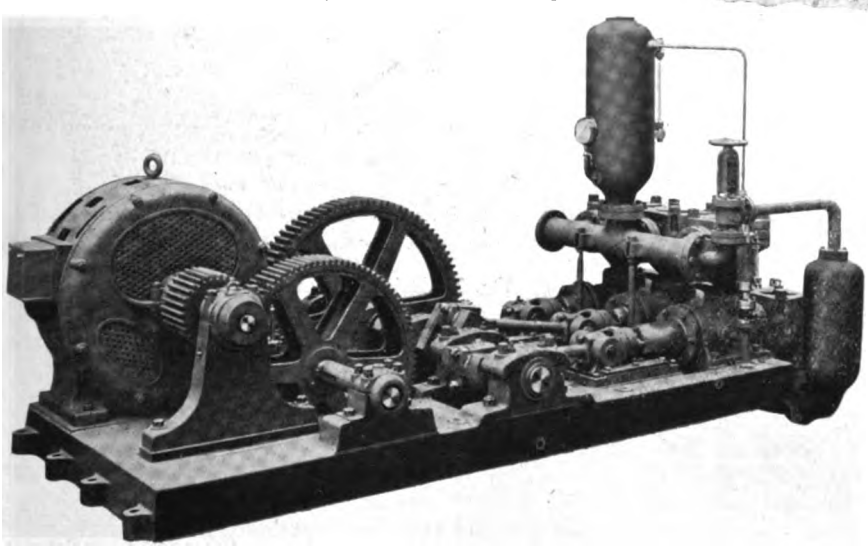

Fig. 2.—Pearn Electrically-driven Colliery Pump.

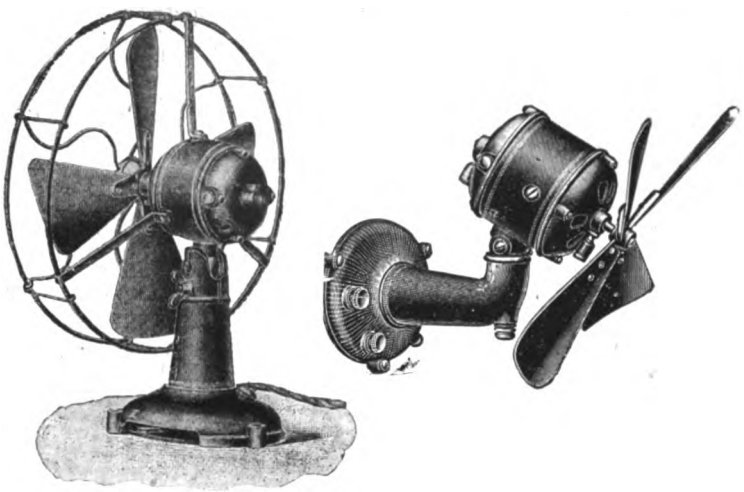
operations. This was constructed for use in the West African goldfields. The pump is capable of delivering 15,000 gallons per hour against a head of 500 ft., the rams being $8\frac{1}{2}$ in. diameter with a 15 in. stroke. The speed is 38 revs per min., the pump being driven through a train of double gears all machine cut, the motor speed being 500 revs. per min. The pump barrels are all in one casting and securely bolted to H section steel girders, these girders in the first instance being connected together by cast iron distance pieces at each end and then treated as though it was a complete casting. The pump barrels are also stayed to the main crankshaft pedestals. All cross strains are eliminated, and the strains on the girders and stays are in tension. Both the crank shaft and intermediate gear are between bearings, and not overhung.

OSRAM LAMPS

Siemens Fans.

AMONG the many specialities manufactured by Messrs. Siemens Brothers Dynamo Works (Ltd.) may be mentioned their table and bracket fans. These are made for continuous or alternating current for voltages varying from 6-220, the air displaced per minute varying from 105 to 1,050 cubic ft.



Examples of Siemens Fans.

In Fig. 1 we illustrate a 12 in. fan provided with a knee joint, speed reducing switch and wire guard, the knee joint making it suitable for use either as a table fan or, without alteration, for fixing on the wall as a bracket fan.

Larger size fans are provided with a special regulator to reduce the speed by about 33 per cent. Alternating-current fans are provided with induction motors which run silently, and these, having neither commutator, slip-rings nor brushes, can be left running for long periods without attendance. Fans for installing in damp situations are provided with special insulation.

Fig. 2 shows one of the Siemens type GMT fans with knee joint arranged as a bracket fan.

Turbine-driven Centrifugal Boiler-feed Pump.

THE first requisite of a boiler-feed pump is the ability to give uninterrupted service while receiving little, and often unskilled, attention. The centrifugal pump, however, is free from many of the disadvantages of the reciprocating pump, and possesses several important advantages in addition. An interesting pump of this type is described in a recent issue of the "Electrical World." The impeller is of bronze and there is an absence of guide vanes. One of the chief obstacles to high head per stage in certain types of centrifugal pumps has been the leakage from the discharge, past the impeller, back to the suction chamber. In this pump this has been prevented by the use of special labyrinth packing rings instead of the plain, straight, water-packed joint commonly employed. At each joint there is one labyrinth ring attached to the impeller and another meshing with it set into a recess in the pump casting and secured in place by the act of letting the cover down upon the lower pump casing. The two labyrinths intermesh in such a way as to form a long, tortuous passage in which any leakage currents are repeatedly broken up. At the same time the water within the labyrinth is set in motion by the drag of the moving ring, creating a counter centrifugal force in opposition to the leakage.

The casing of the pump consists of two parts only: the bottom casting and the cover casting. In the bottom casting are formed the inlet and outlet passages to the piping, while both castings contain passages leading from the delivery of the first impeller to the inlet of the second, these passages being cast in the solid metal. The top, or cover casting, when raised, exposes the entire interior and all working parts of the pump, and, after removing the shaft-bearing caps, the impeller may be lifted out entire.

Balcke's Centrifugal Pumps.

THE various advantages attendant on the use of that dual combination the centrifugal pump direct-coupled to a motor, are so well known to our readers in a general sense that it is unnecessary to dilate further upon them. But we may give some examples of this general

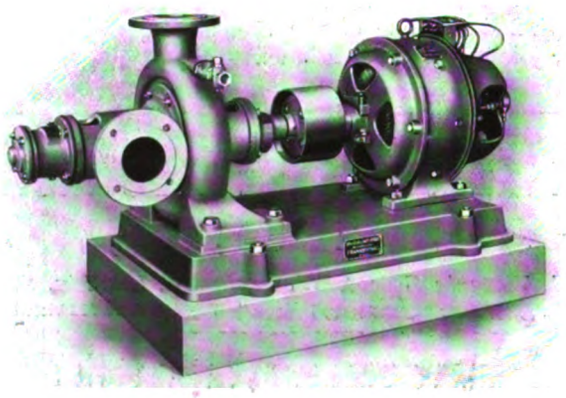

Fig. 1.—Balcke Low Lift Centrifugal Pump.

droposition, and for this purpose cannot do better than describe the low lift centrifugal pumps made by Messrs. Balcke & Co.

All these pumps are provided with guide vanes to convert the velocity when leaving the impeller to static pressure with minimum loss. The larger sizes have also a spinal casing for obtaining the most favourable flow of water.

The speeds of the standard patterns have been kept within moderate limits. For higher speeds, which may be required for coupling to a high-speed motor, a pattern with a double inlet is recommended. In these pumps the width of the impeller is increased at the same time as its diameter is reduced.

The water enters the impeller through a suction bend cast on the pump cover. From the impeller it flows at a higher speed into the guide vanes, which form part of the casing, where its velocity head is converted into pressure and ordinary pipe velocity without undue loss due to friction or whirling. The position of suction and delivery branch can, in each case, be altered to suit any piping arrangement. By most accurate workmanship, it is claimed, the water loss is reduced to a minimum, but at the same time there is no undue friction.

Accurately machined bronze rings, which are easily changed, are fitted between the impeller and the casing. End thrust is entirely prevented by a special design of the impeller. At the same time, for fixing the latter, a light thrust bearing is provided on the suction side of the pump.

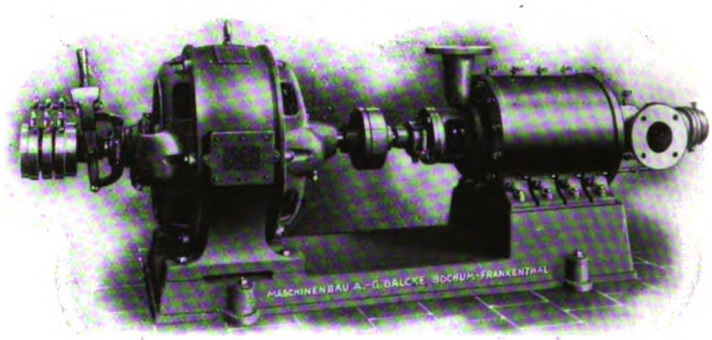

Fig. 2.—Balche Three Stage Turbine Pump.

The shaft runs in easily accessible bronze ring oiled bearings, which are entirely separate from long glands. These latter can easily be got at and are water sealed on the suction side to prevent air entering the pump.

The pumps can be driven by belt or can be coupled direct to a motor, steam engine or steam turbine.

Fig. 1 shows an example of Balcke's low lift centrifugal pump direct-coupled to a motor. These pumps are made in sizes whose lifts vary from 13 ft. to 82 ft. per minute, the capacity being between 955 and 1,240 gallons per minute. Fig. 2 shows a three stage turbine pump, also electrically driven. These pumps can be supplied for any capacity and lift, and are designed specially for use in mines or for boiler feed purposes.

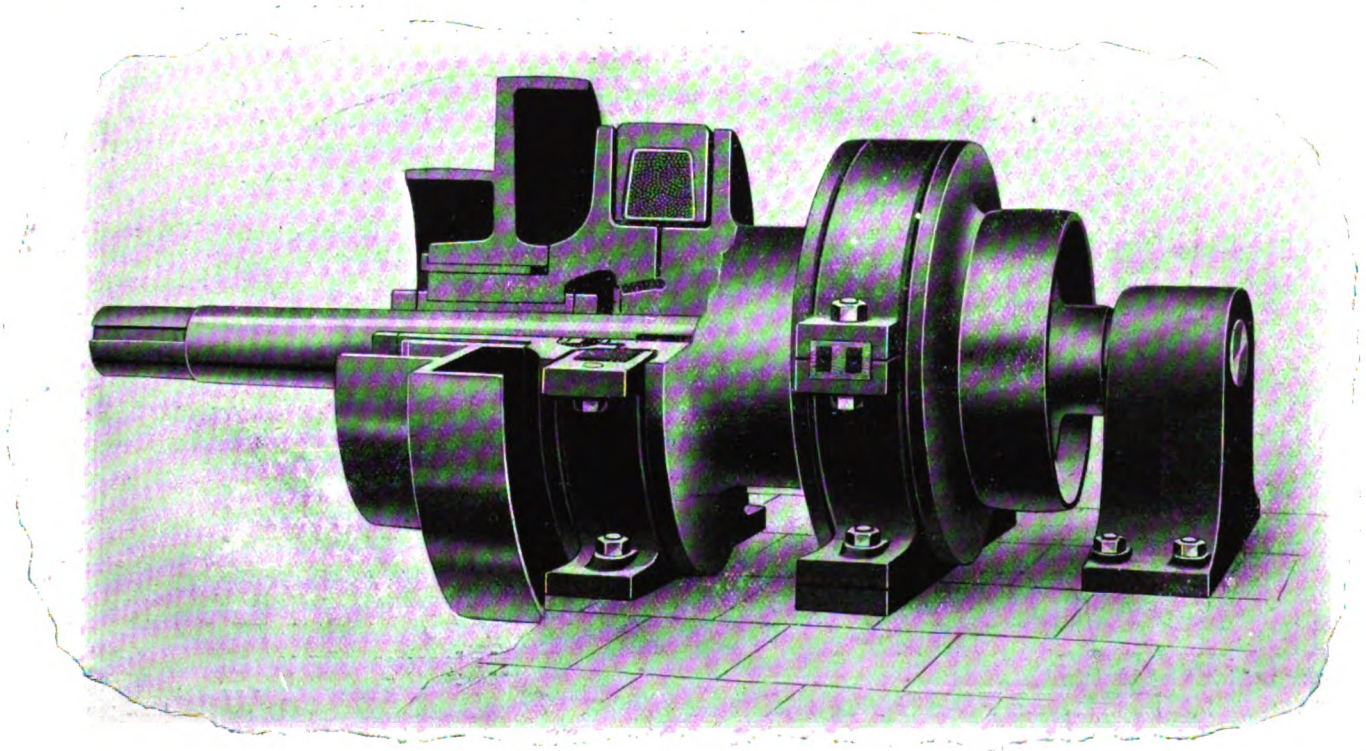
The S.M. Electro-Magnetic Drive.

AN interesting application of the electro-magnet to machine drive is that of the S.M. clutch made by Messrs. C. E. Lugard & Co., of Chester. In this system a reversing magnetic clutch is utilised instead of the shifting belt. This clutch consists of a stationary magnetic body containing a coil ; a divided armature, one part secured to the shaft, and provided with a renewable cone of hard fibre ; the other part running loose on the shaft and carrying the belt pulleys. Continuous current is supplied to the energising coil from the shop mains by wires connected to the stationary magnetic body. As soon as the circuit is closed the two parts of the armature are sucked together by magnetic attraction. The old striking gear is removed, and one of the levers is utilised to move a sliding switch, which automatically energises the clutch. The shaft carrying three belt pulleys and the quick return sleeve and pinion, is replaced by a shaft carrying a double S.M. electro-magnetic clutch fitted with pulleys. All variations in speed are obtained by pulley ratio. The electrical connections consist of a double-pole switch, non-inductive resistance, two single-pole fuses, for connection to the shop mains, and a pear switch with flexible cord for control from a distance.

As an example of the economies effected by this system we may instance the case of an old planer, 5 ft. 6 in. by 16 ft. table, only cutting at 25 ft. per minute, resting $3\frac{1}{2}$ seconds, and returning at 35 ft. per minute, which has been fitted with a magnetic drive. The speeds are now : cutting (two speeds) 28 ft. and 50 ft. per minute, return 60 ft. per minute with no appreciable rest at the end of the stroke. Heavier cuts even at 50 ft. with a reduced load on the motor can now be taken owing to the better grip of the belt. The machine gives $2\frac{1}{2}$ times its former output.

Besides the economies which can be expressed in mere figures there are other decided advantages resulting from the uses of such an apparatus. Much of the old unsatisfactory mechanical equipment is removed, and there remains instead an arrangement which is simple and easy to operate. The clutch takes up but little room and should have a wide application.



General View of the S.M. Clutch.

NOTES.

The Daimler Petrol-Electric Omnibus.

THERE are three main features in the new Daimler petrol-electric omnibus, as our readers will see from the description given in another column, namely, (1) the use of petrol and electric motors in the form of detachable units, (2) the abandonment of the usual chassis, and (3) the use of an all-steel body. So far, the chassis has been a popular form of construction in all motor vehicles, except of the lightest possible type, as any other form of construction with a wooden body renders hard wear an impossibility. The chassis takes up the main stresses in driving, and the body is thus concerned merely with supporting the load of passengers. An all-steel body, however, renders this form of construction unnecessary, as the steel can take up the stresses which would otherwise be met by the chassis, and weight can thus be saved in one direction, although it is necessarily increased somewhat by adopting this construction for the body. The result, as a whole, however, seems to be favourable to lightness.

THE usual claims of the petrol-electric system are that the change-speed gear, which is necessarily associated with the petrol motor when used by itself, is eliminated, and there is much greater flexibility in the driving. Results of this kind have been obtained by previous systems, but probably the most important distinction in the Daimler motor omnibus is that the driving units are detachable. A petrol engine with an electric motor coupled on the same shaft is mounted on each side of the omnibus, and each set drives a rear wheel by means of worm gearing. The weight of the back axle and differential is thus saved, and these driving units are so mounted that they can be removed in quite a short time. A battery of accumulators completes the essential part of the equipment, the motors acting as generators at times. The new scheme seems to be very important from the point of view of maintenance. The engine is essentially that part of the equipment which requires the greatest attention, and satisfactory running cannot be expected unless the engine is kept in thorough order. On the other hand, with the usual arrangement, if the engine is to be overhauled the omnibus as a whole must be thrown out of work, and thus capital is kept idle to a very considerable extent. By adopting the principle of detachable units, this difficulty is overcome, as the engine and motor can be overhauled at leisure under the best conditions, whilst the omnibus is performing its usual task with fresh units. Other points of novelty are the wire wheels, the wire type not having been so far adopted for heavy vehicles, and, further, the much larger diameter of the wheels. It is evident that every care has been taken to reduce the weight to a minimum; and as the larger wheels will result in much smoother running, we do not doubt that the cost of maintenance as a whole will be reduced below the usual figure. We hope that this new type of omnibus will show itself entirely satisfactory under working conditions, that it will prove to be an advance on present practice, and that it will enable the petrol-electric system to compete advantageously with the purely petrol type.

"Golden" L.C.C. Tramways.

ALTHOUGH the result of the past year's operation of the London County Council tramways scarcely justifies the above epithet, used by the "Daily Chronicle," it certainly cannot be considered unsatisfactory. Thus, the report of the Finance Committee on the tramway accounts for the

Digitized by Google

year ended March 31st last, which report was presented to the Council on Tuesday, showed that the balance, after payment of interest and sinking fund, amounted to £192,109. This compares with £107,570 a year ago; and it is satisfactory to notice that the whole of the above sum is to be placed to the reserve fund and as a provision for renewals, notwithstanding the clamour of a certain section of the daily Press that at least some of this "profit" should be handed over to the relief of the rates. It will be remembered that Messrs. W. B. PEAT and F. W. PIXLEY, in their report some two years ago upon the accounts of the Council's tramways, stated that an adequate reserve for future renewals is an essential element in the cost of the year's trading and should be charged before the balance of net revenue is arrived at; so that, as a matter of fact, the real surplus, if any, in the present instance is quite small. In this connection it is instructive to notice the efforts made to beguile the ratepayers into the belief that a "commercial profit" of more than three-quarters of a million has been obtained.

THE work of converting the horse-operated lines proceeds apace, and the Chairman of the Highways Committee stated at the meeting on Tuesday that of the 20 miles of track which remained to be converted on March 31st last, the electrification of 14 miles is now in hand. The difference between the results achieved on the horsed tramways and on the electrically-operated routes is certainly very striking; but as has been frequently pointed out, the two cases are not at all comparable. There is no doubt, however, that although the remaining horsed routes are not likely to show after conversion such a high average revenue as 11·48d. per car-mile, their early electrification will be a decided advantage both to the tramway undertaking and to the public. It is probably partly owing to the fact that the "best paying" routes were converted at an early date that the average revenue per car-mile on the electrically-operated lines continues to decrease, the figures for the past four years being 12·23d., 11·95d., 11·81d. and 11·48d. respectively. On the other hand, in regard to the future prospects of the undertaking, it is very satisfactory to notice that the increase in receipts during the past three months will, if maintained, result in over a quarter of a million additional revenue during the present year.

The Telephone Transfer.

THE proceedings at the sixteenth annual dinner of the staff of the National Telephone Co., held on Thursday evening last week, were noteworthy. The absence of the Postmaster-General, of the Assistant Postmaster-General, and of other departmental leaders was unfortunate, as the presence of the State representatives would have given *éclat* to the occasion. Their absence did not, however, detract in any way from the harmony of the proceedings. It will be seen from our report on another page of this issue that the process of the lion lying down with the lamb is almost an accomplished fact. There is, however, a "fly in the ointment," as the chairman referred to the possible expenditure of £100,000 (presumably in litigation or arbitration) before the complete consummation of the parable. It is to be hoped, in the interests of all parties to the transfer, that this huge expenditure will be avoided, and that the negotiations which have been, and are, proceeding will be brought to an honourable and satisfactory termination. Except for this jarring note, the proceedings at the staff dinner were of a most harmonious character, and the facts and figures presented by the President of the National Company (Mr. GEORGE FRANKLIN) and by the chairman (Mr. ALBERT ANNS) showed, if any such showing were necessary, that the Company, despite the sword which hangs over it, is a virile, progressive enterprise, and promises to be a most valuable asset for the State to acquire. The outlook for the shareholders appears to be an improved one, and if the future position of the staff could be definitely settled we feel sure that the public would regard the State's latest purchase with equanimity and with hope. To the very large number of the Company's staff whose future lies in the lap of the gods, the feeling of doubt and uncertainty is becoming wearisome, and they may reasonably ask their future masters to make an end of this uncertainty by a prompt and, it may be, liberal settlement of all outstanding questions.

L.B. & S.C. Electrification.—Statements continue to be published of the decision of the London, Brighton & South Coast Railway Co. to extend the electrification of their suburban line to the Crystal Palace. The portion of the line which is to be included in the new scheme is that between Battersea, Clapham Junction and Balham to the Crystal Palace, and from Peckham Rye to the Crystal Palace, enabling the electric service of fast trains to be available from either Victoria or London Bridge and the intermediate stations to the Palace. Those who are concerned in the future of the Crystal Palace regard the Company's decision as a most important one in that interest.

Kew Observatory.—In accordance with recent arrangements the administration of the work of the Kew Observatory, in so far as it is concerned with observational and experimental work in meteorology and geophysics, is to be transferred to-day to the Meteorological Office. The administration of the observatory at Eskdale Muir is also to be associated with the Meteorological Office instead of, as heretofore, with the National Physical Laboratory. In addition to continuing as superintendent of the Central Observatory, Dr. C. Chree, F.R.S., has been appointed Assistant Director of Observatories for the Meteorological Office. The work of testing instruments now carried on at Kew will be transferred to Teddington, the well known "K.O." mark being retained by the National Physical Laboratory.

Wireless Telegraph Station at Colon.—According to the "Electrical World," there has been installed in the United States Navy wireless telegraph station at Colon a complete new wireless telegraph equipment, including antenna. The new equipment consists of the latest improved design of Fessenden apparatus. The transmitting apparatus is of the high frequency 500-cycle type, with a rotating spark gap which is attached to a 25 kw. generator. Two compressed air condensers, each operating under 250 lb. air pressure are also used. Power for operating the transmitter is received from the Isthmian Canal Commission plant at Gatun. This equipment was put into operation on March 1st last and has since operated satisfactorily.

Increasing the Speed of Telegraphic Transmission.—It is stated that by means of an invention due to Mr. Hans Knudsen the speed at which telegraph messages can be transmitted will be quadrupled. Mr. Knudsen proposes to dispense with the Morse code of signals and to employ a lettered keyboard. The message at the receiving station is to be automatically printed by a typewriting machine, thereby simplifying the operation at transmitting and receiving stations.

Personal.—On June 15th the honorary degree of doctor of science was conferred on Mr. H. F. Parshall by the Massachusetts Institute of Technology. Mr. Parshall is well known in this country, though his early engineering days were spent in his native country, the United States. From 1887 to 1898 he occupied responsible positions with the Sprague Electric Railway & Motor Co., the Edison General Electric Co. and the General Eletric Co., while he was also a lecturer in electrical engineering at the Massachusetts Institute of Technology.

Birthday Honours.—We are glad to see that some names well known in the technical world appear in this year's list of Birthday Honours, though pure science has not received as much attention as might have been expected. The following is a list of those names best known to our readers :—

Barons.—Sir WEETMAN D. PEARSON, Bart., head of S. Pearson & Son (Ltd.), railway and tramway contractors, &c. Among the many big engineering works carried out by the firm was the construction of the Great Northern & City (Tube) Railway.

Sir CHRISTOPHER FURNESS, chairman of Messrs. Richardsons, Westgarth & Co. (Ltd.), engineers and shipbuilders.

Privy Councillor.—Sir WILLIAM MATHER, chairman of Messrs. Mather & Platt (Ltd.), the well-known electrical and mechanical engineering firm. Apart from engineering, Sir William has for many years been a consistent and generous supporter of technical education.

Baronet.—ALFRED MOND, M.P., a managing director of Messrs. Brunner, Mond & Co.

Knights.—ALFRED HOPKINSON, K.C., LL.D., Vice-Chancellor and Principal of the Victoria University, Manchester.

CLARENDON HYDE, a director of the Great Northern & City Railway Co. and of S. Pearson & Son.

C.B.—RICHARD TETLEY GLAZEBROOK, Director of the National Physical Laboratory. Dr. Glazebrook is a Past-President of the Institution of Electrical Engineers, a Past President of the Physical Society, and the author of several works on optics and physics, a life of Clerk Maxwell, &c.

C.I.S.O.—ALFRED E. EAMES, retiring Comptroller of the Central Telegraph Office, G.P.O.

Street Railway Development in the United States.—Some interesting figures regarding the development in tramway mileage in the United States are given in a leaflet recently issued by the Department of Commerce and Labour. From these it appears that electricity is used as a motive power on 99 per cent. of the lines, while in 1907 the total number of miles of line, by which is meant length of first main track or road bed, was 25,547·19, compared with 16,645·34 in 1902, the per cent. increase being 53·5. The total number of miles of track, meaning the total length of all trackage, including sidings, was 34,403·56 in 1907, as against 22,576·99 in 1902, the per cent. increase amounting to 52·4. Of the total number of miles of track, those operated by electricity in 1907 numbered 34,059·69 and in 1902 21,907·59. The per cent. increase was 55·5. The track operated by animal power in 1907 was 136·11 and in 1902 259·10 miles. The per cent. decrease amounted to 47·5. The track operated by cable in 1907 was 61·71 and in 1902 240·69 miles, the per cent. decrease being 74·4. The track operated by steam in 1907 was 146·05 and in 1902 169·61 miles, a decrease of 13·9 per cent. The percentage increase in cost of construction in 1907 compared with that in 1902 was 67·8, while the number of employés increased by 57·3, and the passengers carried increased from 5,836,615,296 to 9,533,080,766. The car-mileage was 1,617,731,300 in 1907 and 1,144,430,466 in 1904. The use of electricity has made it possible to increase the size of the cars so that the number of cars in 1907 was only 16·1 per cent. greater than in 1902 ; and while in 1890 99 per cent. of the traffic was passenger, in 1902 this had fallen to 94·5 and in 1907 to 91·4 per cent.

Improvement of London's Means of Transport.—At a meeting of the London Chamber of Commerce, held on Wednesday last, Mr. A. W. Gattie read a Paper in which he described an arrangement for improving existing traffic conditions in London. He holds the view that the greater part of the present congestion is caused by the vans of the various railways and parcels agents and traders, and that these carts not only stand about for long periods, thus blocking the road, but also hardly ever carry more than half their normal load. Further, the large size and present arrangement of our goods stations prevents the produce being effectively dealt with, with the result that a large amount of time is wasted on the journey. To overcome these difficulties Mr. Gattie proposes to apply the clearing house system to railway goods traffic. He would erect one large clearing house in the Clerkenwell-road to which would be carried all goods intended for transport by rail. At this clearing house the goods would be sorted into the towns, while they would also be so arranged that they would be quite ready for despatch at the other end by a similar arrangement. This method of working would include all forms of merchandise except coal and cattle. The building has been so designed that the Clerkenwell-road would run right through its centre, while the other neighbouring main streets would be well available for bringing up the goods. Clearance, after sorting, would be by two special lines of rail connecting up the trunk railway systems north and south of the Thames. Although this idea is likely to be of interest to the electrical engineer in his public capacity, yet the point that will appeal to him most is the way in which electric power is to be used in marshalling and arranging the goods within the clearing house. The parcels are not, in fact, to be touched by hand at all, but would be distributed by cranes or conveyors to the railway trucks, which are timed to receive them at a particular point. The conveyors are fitted with electromagnetic apparatus which enables them to suck on to themselves or to thrust from themselves loads which are deposited beside them on suitable magnetic trays or tables ; and, by means of a controller, they are able to do this in a way predetermined by the operator. Neither the function of receiving nor discharging a load involves any shock or concussion. This result is achieved by the use of reciprocating roller magnets, which revolve at the same speed, one set being fixed at the station, the other set being carried by the moving platform. The switching arrangements are intricate, and it is impossible to indicate them briefly, but we hope we may be able to return to this part of the subject when it has been more fully developed. The patents are in the names of Mr. Gattie and Mr. A G. Seaman of the British Westinghouse Co.

Magnetic Separators.—At a meeting of the South African Institute of Electrical Engineers, an interesting discussion took place on the extraction of iron from ore and pulp. The presence of iron in mill pulp is undesirable from several points of view. It interferes with the cyanide tretament, as it absorbs oxygen ; it is separated together with the heavier bodies and returned over and over again to the tube mills to be reground until it is passed on to the cyanide works. The quantity of iron present in the pulp is approximately 4 lb. per ton, and as this increases the expense a simple means for its removal is desirable. The most favoured idea seems to be a magnetic separator. Mr. C. McCann described briefly the separator installed at the Premier Mine for the extraction of magnetic substances from the concentrates before going to the sorting tables. Although some 32,000 tons of ground are crushed and treated per day, the concentration methods are so good that only about 1 ton of concentrates per day, containing the whole output, needs treatment by this machine. The method of treatment is as follows : The concentrates are fed by hand into a hopper which distributes them over a slowly moving canvas belt some 4 ft. wide ; on this belt they first pass under a narrow magnet placed across the width of the belt, and along the face of this magnet runs a small canvas belt. All metallic iron particles are attracted and lifted up by this magnet and carried and thrown on one side by the small belt. They amount to about 10 per cent. by weight of the concentrates. The remainder is then carried on by the main belt, and allowed to fall between the poles of a pair of powerful magnets, where they are divided by a knife edge, the non-magnetic particles dropping straight down and the others

Digitized by Google

being deflected. A peculiar fact in connection with the operation is that practically the whole of the above-mentioned second stream of matter consists of what are generally believed to be non-magnetic substances, and are so, in an ordinary field, such as that produced by a powerful horseshoe magnet. In samples taken on several occasions Mr. McCann was unable to detect any particle showing signs of magnetism. Chemical analysis also failed to show any general trace of iron, but traces of oxides and sulphides were found in a few samples, also a few traces of nickel, in the form of nickeliferous pyrrhotite, which is a magnetic compound. The field which produces this unusual degree of separation is an exceedingly powerful one (B=20,000 lines per square centimetre, estimated). The pole pieces are about 4 ft. to 5 ft. wide, and are wedge shaped, tapering from some 6 in. or 8 in. to a curve of about $\frac{1}{4}$ in. radius, at which part, of course, the flux is concentrated. The main energising coils are four in number, each resembling one of the field coils of a large two-pole dynamo. The current taken by these is about 40 amperes at 500 volts. Mr. McCann mentioned that the figures given as to dimensions and current were, to the best of his recollection, correct, but were subject to correction.

Submarine Power Cable.—According to the "Electrical Review and Western Electrician," the American Steel & Wire Co. recently laid what is said to be the first long-distance submarine cable for high-voltage transmission in an inland lake. The cable was laid on the bottom of Oneida Lake, New York, from a point several hundred feet east of the South Bay terminal of the Syracuse & South Bay Electric Railroad to the east shore of Frenchman's Island, a distance of more than 6,000 ft. The cable consists of three conductors No. 5 B. & S. gauge, insulated with special crown-rubber insulation to the depth of $\frac{3}{16}$ in. around each conductor, with jute laterals, and wound with two reversed saturated jute servings. It is armoured over all with No. 9 galvanised iron wires. Power will be transmitted at 6,600 volts and stepped down to 110 volts at the island, where it will be used principally for illuminating the dancing pavilion, groves and dock.

Street Railway Accidents in New York.—The Public Service Commission of the First District of New York has recently issued a comparative statement of the accidents which occurred on the street railways in the district under its jurisdiction for the month of April in the last three years. The following summary is given by the "Electric Railway Journal":—

	April, 1908	April, 1909	April, 1910
Car collisions	140	88	99
Persons and vehicles struck by cars	930	994	963
Boarding	562	563	690
Alighting	544	557	625
Contact with live conductors	36	21	26
Other accidents	2,498	1,947	1,920
Totals	4,710	4,170	4,323
Injuries:—			
Passengers	1,681	1,610	1,828
Not passengers	662	484	487
Employés	503	400	490
Totals	2,846	2,494	2,805
Serious Injuries (included in above):—			
Killed	30	28	36
Fractured skulls	24	8	9
Amputated limbs	5	3	8
Broken limbs	30	18	38
Other serious injuries	102	120	133
Totals	191	177	224

In explanation, the Commission says that the increase in the number of persons killed is accounted for partly by the fact that 2 of the deaths were from suicide, 6 from employés working on tracks, and 10 from stealing rides, falling from structures, trespassing, contact with live conductors, &c. No one was killed in collisions between cars, and only one person was killed from collisions between cars and vehicles. Nine persons were killed by being struck by cars this year, as against 12 last year.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Mr. J. M. Fernandez contributes an article on "A New Arrangement for the 'B' side of Quadruplex Apparatus."

The latest form of Collins Wireless Telephone is described in our columns by Mr. W. Dubilier.

Mr. D. Owen contributes an article on "Short Spark Gaps."

The new exchange of the National Telewriter Co. is being opened by the Lord Mayor of London to-day. The exchange is situated in the City.

A new type of petrol-electric motor omnibus has been constructed by the Daimler Motor Co.

We conclude our account of Sir John Gavey's "James Forrest" lecture on "Recent Developments in Telegraphy and Telephony."

In presenting the Post Office estimates in the House of Commons on Thursday of last week the Postmaster-General (Mr. Herbert Samuel) gave interesting particulars of the Post Office telegraphs, telephones, wireless telegraphy, &c.

Islington (London) Borough Council have decided to increase the capacity of certain of the electricity supply mains at a cost of about £20,000 and to provide a new main switchboard at a cost of £3,000.

Leicester Corporation have decided to separate the electricity and gas departments and to place the electricity department under separate management.

Companies Meetings, &c.—The directors' report of the Rio de Janeiro Tramway, Light & Power Co. for 1909 gives particulars of the progress made in the tramway, lighting and power and telephone departments of the Company during 1909.

INSTITUTIONS AND SOCIETIES.

Royal Society.—Among the Papers read at the meeting of this Society yesterday afternoon were the following: "On the Scattering of Homogeneous β-Rays and the Number of Electrons contained in an Atom," by Mr. J. A. Crowther, and "A Determination of the Ratio of Mass to Weight for a Radio-active Substance," by Mr. L. Southerns.

Merchant Venturers' Technical College, Bristol.—The speech day of this college will be held in the Great Hall on Friday, July 22nd, when the Master of the Society of Merchant Venturers (Col. F. C. Ord, C.B.) will distribute the prizes.

Academie des Sciences.—Sir Wm. Ramsay, F.R.S., has been elected an associate member of this Society.

Institution of Electrical Engineers.—The annual conversazione was held on Tuesday evening last at the Natural History Museum, South Kensington, the guests being received by Dr. Gisbert Kapp, president, and Mrs. Kapp and the Council of the Institution. The attendance was very small compared with that in recent years, probably less than half the usual number of guests being present. A programme of music was performed in the Central Hall of the Museum by a portion of the string band of the Royal Engineers, whilst the Alexandra Ladies' Quartette gave an entertainment in the Shell Gallery.

The Association of Mining Electrical Engineers.—An interesting diversion from the usual proceedings of the Mining Electrical Engineers took place on Saturday last, June 25th. A large party of the members of the Newcastle Branch and their lady friends joined together in a picnic, visiting Ripon and Fountain's Abbey. Luncheon was served at the Unicorn Hotel, Ripon. Dr. Thornton, who was in the chair, expressed a few encouraging remarks concerning the objects and work of the association.

ARRANGEMENTS FOR THE WEEK.

FRIDAY, July 8th.

Physical Society.

5 p.m. Meeting at the Imperial College of Science, Imperial Institute-road, South Kensington. *Agenda:* "A Thermo-electric Balance for the Absolute Measurement of Radiation," by Prof. H. L. Callendar, F.R.S.; "The Convection of Heat from a Body Cooled by a Stream of Fluid," by Dr. Alex. Russell; "On Hysteresis Loops and Lissajous' Figures, and on the Energy Wasted in a Hysteresis Loop," by Prof. S. P. Thompson, F.R.S.; and on "The Energy Relations of Certain Detectors used in Wireless Telegraphy," by Dr. W. H. Eccles.

ANNUAL REPORT OF THE ELECTRICAL INSPECTOR OF FACTORIES.

The annual report of the Chief Inspector of Factories, Dr. B. A. Whitelegge, C.B., was issued last week, together with the various sectional reports, including that of Mr. G. Scott Ram, Electrical Inspector of Factories.

In the general report the Chief Inspector refers to the importance of the adequate lighting of workrooms. The question of standards, he says, is beset with difficulties, and, in the absence of a standard, a broad requirement of adequate lighting is only a half-measure. As regards artificial light, other considerations arise, apart from contamination of the air by all except electric light and ventilated gas burners—namely, the quality of the light and the intensity of the source from which it is radiated, that is, glare. It appears that artificial light in which the rays from the violet end of the spectrum predominate may on that account be less efficient, at all events for certain kinds of work, and that radiation from a small but intensely luminous source, such as an unshaded electric light, may be more trying to the sight, and hence less effective, than the same amount of light diffused from a larger surface. The subject as affecting industrial employment is not one which admits of settlement by a stroke of the pen, and close investigation of the conditions will be necessary. As a beginning, Mr. D. R. Wilson has been directed to inquire into the present lighting of certain classes of workrooms, beginning with underground bakehouses in London.

There is no question that this subject is important, but electrical engineers generally will be more interested in the report of Mr. Ram, of which the following is an abstract:—

The Electricity Regulations made by the Secretary of State on December 23, 1908, came into force generally on July 1, 1909, and on January 1 of this year as regards such parts of electrical stations as were constructed before July 1, 1908. The distribution of the code and the registration of the premises affected have entailed a considerable amount of work upon the staff in the various districts owing to the large number of premises concerned. During the year I made a number of special visits, at the request of occupiers, in reference to the application of the regulations on their premises, and, in accordance with instructions, prepared for publication a memorandum* explaining the effect of the regulations and the exemptions therein allowed in the several classes of works and installations to which they apply.

The reports from the staff show that those occupiers employing responsible electrical engineers appear generally to be taking steps to comply with the regulations, but that there is a good deal of difference of opinion as to what is sufficient, and adequate, and that some general guidance in interpretation, such as the Memorandum is intended to supply, is very generally desired. Many firms do not, however, employ electrical engineers, and have little idea as to the meaning of many of the rules, though in the majority of such cases the supply is taken from public mains, and the electricity supply authorities to some extent co-operate with the officers of the Department in seeing that the requirements are complied with. Mr. T. C. Taylor (Norwich) reports that the electricity supply department of a local authority in his district is prepared to give a certificate that to the best of their knowledge the installations supplied from their mains are in accordance with the requirements of the Regulations. There is no doubt that public supply electricity undertakings might do very useful work in supervising the factory installations connected to their mains in reference to the regulations, and in the increasing number of cases where they also put in the installation, it is necessary that they should carefully work to the requirements. While such a certificate would not absolve the occupier from his legal responsibilities, it would, if given only after careful inspection by a competent person fully acquainted with the requirements, afford some assurance to the non-technical occupier that his installation complies with the Regulations.

In reading the Regulations, it is often overlooked by occupiers that many of the terms used carry defined meanings. Attention is drawn to this in the Memorandum, where the Regulations are printed with the defined terms underlined. Exemption 1 (*a*) provides certain exemptions where the pressure of the system does not exceed low pressure direct or 125 volts alternating. The greater number of installations affected by this exemption will be those using direct current. Many are supplied from public mains. In connection with these a question arises in regard to a three-wire direct-current system in which the pressure between the outer conductors may exceed low pressure, but the pressure between the earthed neutral conductor and either of the outer conductors cannot exceed 250 volts; namely, whether the exemption applies to a supply taken from one side only of such a three-wire system. The conditions are precisely similar to what they would be if the supply was on a two-wire system not exceeding 250 volts having one conductor connected to earth, in which case the exemption would apply without question. In either case, the *pressure* on the premises cannot exceed 250 volts. It is explained in the Memorandum that such a supply may be regarded as of "low pressure" and within the exemption *if the neutral conductor of the three-wire system is connected to earth*, as required by the Board of Trade regulations in the case of authorised public supply. This view of the matter will, therefore, extend the benefit of the exemption to many installations which would otherwise be regarded as of medium pressure.

A similar question arises as to whether a circuit fed from an auto-transformer at a pressure of less than 125 volts may be regarded as being under the exemption, the pressure of the supply to the transformer being above the 125-volt limit. In this class of transformer the lower pressure circuit does not form a separate system, but is directly connected to the higher pressure system. If the supply system has one conductor permanently connected to earth at the sub-station or main transformer, and if the tapping from the auto-transformer is taken off the earthed side of the circuit and the arrangement is so carried out that it may be absolutely relied upon, there is no reason why the lower pressure circuit should not be considered as coming under the exemption. The condition must, however, be carefully considered, and the connections properly supervised and carried out by a competent person and subsequently verified by tests. It is necessary that there shall be no break whatever in the earthed conductor between the main supply transformer and the auto-transformer. There must be no fuse or switch therein, as the blowing of the fuse or the use of the switch would cause the whole of the lower pressure circuit at once to assume the full supply pressure above earth. Special attention should also be given to the connections of the auto-transformer that there shall be no possibility of a loose contact. If these conditions are observed so that the pressure of the circuit cannot exceed the limit allowed in the exemption for alternating pressure, 125 volts, either between conductors or between either conductor and earth, the exemption may be considered as applying, but not otherwise. The pressure between the conductors of the circuit being so low, people are apt to regard them as being necessarily free from danger as regards shock, forgetting that unless the above described precautions are carefully observed the danger is represented by the pressure of the supply to the transformer.

It is pointed out in the Memorandum that, although Exemption 1 provides exemption from a number of the regulations where the pressure is below the specified limits, the requirement of general safety is made by Regulation 1, which is not one of the exempted regulations, and that consequently where the specified regulations do not apply, it must not be assumed that there is necessarily no need of any precautions being taken even on the lines of the exempted regulations. Thus Regulation 2 calls for the protection of conductors, but it does not follow that bare conductors up to 250 volts direct or 125 volts alternating may be indiscriminately exposed on factory premises. On the contrary, Regulation 1 provides that they must be so protected as to prevent danger, but does not specify in what manner this is to be done.

During the year I have had submitted to me numerous drawings, samples and models of electrical fittings and apparatus in reference to compliance with the Regulations, often with a request that, if satisfactory, I should give a certificate or other official approval. This, of course, would be not only undesirable for many reasons, but impracticable. I have, however, done all I could to assist manufacturers and others by discussing with them any new designs or methods submitted, after fully explaining the position. A considerable amount of time has, in fact, been devoted to this work during the past year. It is an encouraging sign that some at least of the manufacturers of electrical apparatus should be contemplating new designs in view of the regulations. There is a great deal of inertia to be overcome in the changing of a pattern of any article. There are many faulty designs of switches, fuses, connectors, lamp-holders, hand lamps, &c., which continue to be reproduced. The manufacturers will go on making them so long as people are content to buy them. As, however, attention is now definitely drawn by the Regulations to questions of safety in the construction of apparatus, there is an inducement to the manufacturer to reconsider his designs, and those who are early in the field with improved patterns will no doubt reap the benefit.

One of the most striking examples showing how improved patterns may rapidly supersede old ones when once attention has been directed to the matter is that of hand lamps. In my annual report for 1905, in describing a fatal accident, I first drew attention to the dangers of hand lamps as ordinarily made, and indicated how they should be constructed in order to obviate those dangers. As a result, one firm led the way by taking the matter up and producing a lamp on the lines indicated. In a subsequent report I drew attention to their lamp and further dealt with the matter, showing photographs of lamps which had caused fatal accidents. At the present time a number of firms are making similar "safety" hand lamps for which there is a large demand not only in this country, where now the old types are practically prohibited by the regulations for use in factories, but also from foreign countries and the colonies. Signs are not wanting to indicate that similar attention is now being paid by manufacturers to other forms of apparatus to certain dangerous aspects of which I have drawn attention, and which are capable of similar improvement from a point of view of safety.

In my last year's report in describing accidents with connectors whereby the person in putting in or taking out the plug gets his hand severely burned on account of a short circuit causing arcing at the contacts or within the plug or at the flexible wires close to the plug, I described how a plug could be easily made so as to obviate these dangers, and suggested that manufacturers should give the matter consideration.

* THE ELECTRICIAN, March 4, 1910.

Digitized by Google

The suggestion has been taken up and plugs embodying the features which I described have now been put on the market.

In former reports I have pointed out that fuse-boards are frequently constructed in such a way that the fuses cannot be renewed without danger of shock or burns to the person handling them. This matter is now covered by the Regulations, and further observations on the requirements are given in the Memorandum previously referred to. Although greater consideration is now being paid to this matter, particularly in regard to the larger fuses, improvements in distributing fuse-boards for small sub-circuits have not yet received much attention. Some fuse-boards for use with small sub-circuits, and designed to meet the objections referred to, are illustrated in the Report. In these the fuse wires are attached to contacts fixed in porcelain holders, and they are arranged in such a way that the holders can be readily handled for putting in or taking out of the fixed contacts without danger of touching any live metal, and the operator's fingers are also shielded from the arc should a fuse blow on being put in. The fixed contacts of the fuse-board are also protected by porcelain plates in such a way that they cannot be accidentally touched. These particular distribution boards were designed and put to work long before any regulations were formulated, but they nevertheless serve to illustrate a method for meeting the requirements which might be adopted with advantage by manufacturers to-day, although no doubt there is room for improvement in detail.

Plans of switchboards for new stations or extensions and for the fencing of generators, motor-generators, &c., have also been submitted, and in this connection again, although examination and approval of plans is not called for by the Regulations and cannot be demanded, I have in every case given attention to those submitted, and have in many instances been able to point out where they were at fault in reference to the Regulations, thus probably saving considerable expense in subsequent alterations. In some cases it has, however, been clear that the Regulations had not been studied carefully, if at all, by the draughtsman.

The use of electrical energy for motive power in factories continues to grow rapidly. As in former reports, I have made a comparison of the figures for the horse-power of motors, supplied with electrical energy from the mains of electricity supply undertakings at the end of the year with the corresponding figures for the previous year, taken from the returns published annually by THE ELECTRICIAN. Comparing the figures for those undertakings giving returns for both years, 465,700 H.P. has grown to 556,700 H.P., or an increase of 91,000 H.P. These figures are not complete, some undertakings not furnishing any returns, and they do not include works having their own generating stations. A moderate allowance for these brings the total increase for the year to well over 100,000 H.P., indicating how rapidly electricity is supplanting every other form of power for driving machinery in factories. Concurrently with this increase, the various electricity supply authorities are necessarily adding to the capacity of their generating stations. The additions required to cope with the increased load for motive power purposes alone would represent a generating station larger than any public supply station at present existing in the country, or quite a large number of stations of average size.

The number of accidents at electrical generating stations is set out in the following table. The number of mechanical accidents is almost identical with that of the previous year. Those due to falls form, as usual, a large proportion and include three fatalities. The total number of electrical accidents is also practically identical with that of the previous year, although somewhat fewer occurred in public stations and more in private stations. The number of fatalities is four against two only in the previous year. Of the accidents at switchboards during ordinary routine work, six appear to have been due to faulty switches, in some cases owing to the non-provision of a quick-break action. Several were due to mistakes on the part of the switchman. In four cases the field circuit of a generator was broken at the switch, with the consequent result of an arc burning the man's hand. In two cases heavy arcing occurred at the switch when synchronoising an alternator. Unprotected fuses accounted for three accidents, and four others occurred in the replacing of fuses. Two accidents occurred in operating isolating or selector switches on a high-pressure system. In one case the accident was due to a faulty arrangement of interlocking the switches, and in the other to a mistake in pulling out a switch while it was on full load. Although the switchman was using a special pole, to operate the switch, and was several feet away from it, he was severely burned about the face and hands. A mistake of this kind on a large system is always likely to involve serious injury to the person concerned, and may bring about a complete breakdown of the supply of electrical energy over a large district. In many stations no means are provided for guarding against such mistakes on the part of the switchman. Often there are a number of isolating switches in the same passage way, all exactly alike, sometimes not even distinguished by labels, and a mistake may very readily occur. There are, however, precautions which can be provided in the case of new work and which may often be applicable to existing work. Some recent switchboards have the isolating switches enclosed in cells having doors, which are interlocked with the oil switches used for breaking the circuit in such a way that the doors cannot be opened unless the oil switches are open, and also so that the latter cannot be again closed while the doors to the isolating switches are open, consequently making it impossible to operate the isolating switches under current. In other cases the isolating switches are worked by gearing from outside the cell doors, which do not therefore have to be opened, and the gearing is interlocked with the mechanism of the oil switches. These methods are generally only applicable for new work. For existing switchboards, where a positive interlocking arrangement may be impracticable, it has been suggested to provide an ammeter or current indicator on each conductor, just below the isolating switch, so as to indicate whether a current is flowing or not. Such an arrangement could generally be readily applied and would not be costly. It might also often be practicable to provide an indicator at the isolating switch, mechanically operated from the gearing of the oil switch, to show whether the latter is open or closed. It has also been suggested to provide an arrangement whereby two operations are necessary in opening an isolating switch. In the first operation the switch blade can only be pulled out of contact a very small distance, say, $\frac{1}{10}$ in., so that if a mistake has been made and current is flowing it can be immediately closed again before the arc assumes dangerous proportions. I am not aware, however, whether the method has been tried or would prove successful.

Table I.—*Accidents at Electrical Generating Stations and Sub-stations in 1909.*

Description.	Companies and local authorities giving a supply by way of trade, and electric railways.		Private stations.	
	Non-fatal.	Fatal.	Non-fatal.	Fatal.
Non-Electrical.				
At engines, pumps and generators	26	1	11	—
At boilers and steam plant	56	—	6	—
At coal handling plant	12	1	1	—
Falls	97	3	8	—
Struck by falling bodies	23	—	3	—
Miscellaneous	99	1	9	—
	313	6	38	—
Electrical.				
At switchboards, when engaged in ordinary routine work—mostly due to faulty design of apparatus, or to mistakes on the part of the switchman	16	—	8	—
Cleaning, repairing, &c., at "live" switchboards or other "live" conductors	26	4	20	—
Cleaning, repairing, or other handling of switchboards or apparatus supposed to have been made "dead":—				
Skilled persons	1	—	1	—
Unskilled persons	—	—	—	—
Adjusting brushes and cleaning or lubricating commutators	6	—	3	—
Miscellaneous	5	—	—	—
Total	54	4	32	—

Accidents to persons cleaning, repairing, or otherwise working upon or near live conductors form, as usual, the largest class, and include four fatal cases. Three of these occurred to unskilled labourers who were employed near exposed conductors at extra high pressure. Since Jan. 1st this year the employment of unskilled persons under such circumstances is forbidden under the Regulations, and such accidents, should they occur in the future, may therefore involve serious consequences to those responsible. The fourth fatality occurred to a sub-station attendant, presumably competent, but who evidently overlooked the danger of the work he was engaged upon, viz., disconnecting a transformer for removal.

Two accidents resulting in serious injuries occurred to sub-station attendants working on switches which had been made dead, but which were in close proximity to live conductors at extra high pressure not screened off. In two cases, labourers were again employed close to high-tension conductors, with which they came in contact. Thirteen accidents were due to short-circuits by men engaged in working on live switchboards at low or medium pressure. Most of these accidents appear to have been due to the want of elementary precautions.

The number of accidents set out in Table II. is slightly more than last year, but the fatalities are fewer. The accidents due to the arcing of switches, including motor starting switches, are mostly caused by defects in the switches themselves, or by faults in the circuits controlled by them, but sometimes by mistakes on the part of the operator. The injuries are burns to the hand and sometimes to the arm and face as well, and often injury to the eyes. The use of cheap switches, too small and flimsy for the work, is not unfrequently the primary cause. The accidents from arcing of fuses nearly all occur through the use of unprotected open fuses. Ten of these were on motor starting panels where the fuses were placed near the switch handle, resulting in the operator getting burnt on the hand and arm, and sometimes on the face. The accidents in the renewing of fuses were mostly due to short-circuits in replacing wire or metal strip fuses in live terminals.

Of the accidents with portable apparatus, 23 were due to burns from short-circuits, or shock, when handling the flexible wires. Frequently the flexible wires are insufficiently protected against damage, ordinary "household" flexible being used instead of "workshop" flexible, or, if the latter, it has been damaged and not repaired or renewed. Twelve

were due to short-circuits at connectors when plugging in or out, the operator getting his hand severely burned. Three were due to shock from portable lamps, one being fatal. This occurred on a 250 volt alternating circuit.

Of the non-fatal accidents under this heading, 13 were due to unprotected wires within reach of any person employed. In some cases the wires were bare and in others they had been covered with insulating material which had become damaged owing to absence of any further protection. Seven occurred on ships under construction, in connection with temporary installations, where the wires are liable to very rough usage. Constant supervision is necessary with such installations to ensure safety. Two accidents occurred in engineering works to men who touched live conductors with bars of iron. Two were due to unprotected switches in the driving cabins of cranes. Accidents to skilled persons when working on live conductors in factories ought not to occur, as there is seldom any real need for the work to be undertaken while the conductors are live. Unskilled persons working on live conductors generally do so under instructions from others, and not on their own initiative. Persons employing unskilled labourers and others on such work assume a serious responsibility in doing so.

The accidents in electrical manufacturing works, mostly in testing operations, occur chiefly to apprentices or improvers. The average age of the persons in the 30 cases recorded is only 22 years. As I have mentioned in former reports, apprentices generally seek employment in the testing departments for the sake of the experience to be obtained, and as they have generally had some training in technical colleges, the arrangement suits the employers. Frequently, however, the supervision of the work by experienced persons is insufficient and the precautions taken are inadequate. Amongst the miscellaneous accidents, several occurred through want of efficient earthing.

In my visits during the year, I have seen further examples of dangerous plant, such as I have fully described in former reports. I found some examples of sub-stations in which bare extra high pressure conductors were exposed in the passage ways without any protection whatsoever. I have frequently observed that a generating station which is dirty is generally also one in which the plant is ill-kept and often dangerous. A high-pressure station of a local authority I found to be no exception to the rule. It is noteworthy, also, how some occupiers or engineers will provide ordinary precautions of safety only so far as their legal obligations require. In other places where I had previously visited, I found many improvements had been effected. In several high-pressure generating stations I found that open fronted cellular type switch-gear was being supplanted by other types having no conductors at high pressure accessible from the working platform.

At the public inquiry into the draft Regulations, it was urged by a considerable section of the objectors that the display of a set of instructions for dealing with persons suffering from electric shock would have the effect of retarding the use of electricity by unnecessarily frightening the persons employed. I have not found any evidence in support of this supposition. On the other hand, " danger " notices are sometimes used with the deliberate intention of frightening people in a manner which is quite unnecessary. In such cases the occupier, probably not understanding wherein danger may lie, appears to be under the impression that in providing the notices he is absolving himself from responsibility in case of accident. I do not, however, wish to convey that danger notices are not desirable or necessary under certain circumstances. In an ordinary factory installation, however, there should be no exposed conductors with which persons employed may accidentally come into contact in the course of their ordinary employment, and any switches or other apparatus which unskilled persons may have to use should be so protected that there is no danger. In electrical stations it is often desirable in switchboard passage-ways to draw attention to the presence of high-tension conductors, although only authorised persons are allowed to enter. It is, however, quite as effective and more polite to word the notice " Danger—High Tension " than to put " Sudden death " with a skull and crossbones.

An electrical process, which has been for some years in use in the United States, has been recently introduced in this country. It is for neutralising the static charge of electricity produced by friction, which causes trouble in certain processes such as paper making, printing, and in textile mills, and thereby avoiding the use of humidifiers, steam jets, and gas flames. An " inductor " is placed at some point in the machine where the charged material passes by it at a distance of from 1 in. to 3 in. An alternating electrical discharge takes place from a number of points on the inductor neutralising the charge in the material. The inductor is connected to one pole of a high-tension transformer, the other pole of which is earthed, and also connected to the framework of the machine. The inductor consists of a number of condensers to which are attached the discharge points. A highly insulated conductor passes through the centre of the inductor. Outside the insulating covering of the conductor are a number of copper bands, each with a point attached. These are enclosed in porcelain blocks having holes for the discharge points. The whole is enclosed in a steel tube slotted on one side where the porcelain blocks project. The transformer is specially designed so that it can give only a very small current, and it is claimed that for this reason there is no danger from the high voltage produced, and that in fact there is no danger to a person taking hold of both terminals of the transformer. I have not, however, seen any such practical demonstration, nor have I yet had an opportunity of witnessing any tests bearing on the safety of the apparatus, and for the present I therefore prefer to regard it as potentially dangerous and needing very carefully devised precautions against accidental shock to the persons attending machines to which it is attached.

A NEW ARRANGEMENT FOR THE "B" SIDE OF QUADRUPLEX APPARATUS.

BY J. M. FERNANDEZ.

In quadruplex working it is known that one of the former difficulties was the breaking of the incoming signals at the non-polarised or " B " side, caused by the operation of the reversing

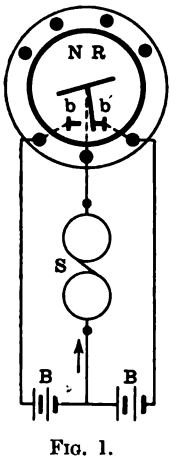

Fig. 1.

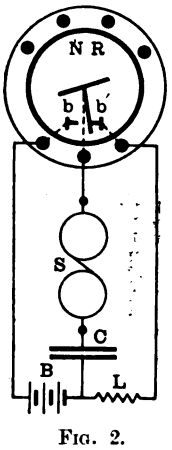

Fig. 2.

key at the distant end. To overcome this difficulty the use of the relaying sounder was generally accepted, although some telegraph engineers suggested different arrangements to avoid its use for the sake of simplicity.

Working in "decrement"—that is to say, decreasing the strength of the normal current by the operation of the B key—was one of the methods suggested; but it has the disadvantage of requiring the strongest current to be on the line during the longer periods, and has been practically abandoned.

Digitized by Google

The author has devised a novel arrangement which meets the requirements and is very simple. Referring of Fig. 1, NR is the non-polarised seven-terminal differential relay; S a polarised sounder, neutrally adjusted, so that its lever will remain against either top; B the battery. Normally, the current flowing through b' and S in the direction of the arrow maintains the lever of the sounder against the upper top; when the relay is operated its lever comes in contact with b, and a signal is produced by the reversing of the current through S.

This signal will not be disturbed when the distant battery is reversed, though the contact at b may be broken at that time, because to release the sounder it would be necessary that the relay lever should cross the gap and make contact at b', since to affect the sounder it is necessary not only to stop the current but to reverse its direction.

Fig. 2 shows the preceding arrangement modified to obtain same results without having the current from battery B flowing all the time. The polarised sounder is then operated by the successive charges and discharges of the condenser C. Both arrangements as described will work in any line where a "decrement" quadruplex can be worked without any of its disadvantages and giving firmer signals, specially appropriate for repeating, as every dot or dash is longer in the sounder, since it lasts not only while the relay lever is against the marking contact but also during the time it takes to cross the gap.

When the KR product of the line is very high, it is necessary to delay further the release of the sounder lever, which can be obtained by inserting a self-inductance coil in the circuit to contact b'.

DUBLIN UNITED TRAMWAYS.*

BY R. S. TRESILIAN.

Summary.—The author describes the development of tramways in Dublin from the year 1867 to the present time. Brief particulars are given of the existing power station and the distribution of electrical energy.

As the Dublin United Tramways Co. was practically the pioneer in the United Kingdom of modernised electrical traction, a short sketch of the history of the Company may be interesting to members of the Association on this their first visit to Dublin. The idea of laying down rails in the public thoroughfares on which carriages with flanged wheels could run was scarcely conceived when the principle was adopted in Dublin. In May, 1867, the City of Dublin Tramways Co. obtained under the Tramways (Ireland) Act, originally intended to apply to country roads only, an Order in Council authorising the construction of a line of tramways. In 1870 a Bill was lodged in Parliament, and in the following year, 1871, became law, incorporating the Dublin Tramways Co., with a capital of £240,000, and authorising the construction of about 17 miles of tramways. The contract for the construction was in July, 1871, entered into with Messrs. Fisher & Parrish, who had previously constructed tramways in London and Liverpool, and in December, 1871, the Company purchased the rights of the City of Dublin Tramways Co. referred to above. A box rail weighing 53 lbs. to the yard, spiked to wooden longitudinal sleepers, cross tied, was used, and sett pavement was laid between the rails and for 18 in. outside each other rail at the expense of the Company, and at an immense saving to the local authorities, as previously all the streets in Dublin were laid with macadam. The cost of construction was about £3,550 per mile of single line. On February 1, 1872, the line from Stephen's Green to Terenure, about 2½ miles in length, was opened for public traffic.

The completion of other lines, authorised by the Act of 1871, quickly followed, and in August, 1874, 16 miles of route were open for traffic, and the gross profits for that year amounted to £14,907. 16s. 10d. from 5,269,546 passengers. The prosperity of this Company was so great that imitators and competitors quickly appeared, eventually leading in the closing months of 1880 to an amalgamation being effected between the companies and to a new company, the Dublin United Tramways Co. being incorporated by Act of Parliament, into whose control the whole of the lines in the city and suburbs of Dublin, except those of the Dublin Southern District Tramways Co., passed. This last mentioned Company had been incorporated by an Act of Parliament obtained in 1878, and later amalgamated with the Blackrock and Kingstown Tramways Co., which had been incorporated in 1883. After trying steam as a motive power these Companies eventually, in 1895-6, converted their lines to the overhead trolley system, a power station being erected at Balls Bridge, and they also projected a very large scheme with the avowed object of competing directly with the Dublin United Co. Negotiations between the owners of the shares of the Dublin Southern Co. and the Directors of the Dublin United Co., resulted, a little later on, in the purchase by the latter of the whole of these shares. In the same year the Dublin United Co. lodged a Bill in Parliament to obtain powers to electrify the whole of their lines, but Parliament, owing to the opposition of the Dublin Corporation, refused to give its sanction to these powers inside the city, and in consequence powers to electrify certain portions lying outside same were only obtained. In order to carry into effect the amalgamation of the undertakings, the present company, the Dublin United Tramways Co. (1896), was incorporated in 1896 under the Companies Acts and acquired all the shares of both the Dublin United and the Dublin Southern Companies and the whole working thus passed under one management.

For the purpose of following the growth of tramway traffic in Dublin and suburbs, it may be well here to state that for the half-year ended December 31, 1896, the first half-year of the consolidated working, there were 41·31 miles of track in operation, the section from Haddington-road to Dalkey only being worked by electricity and the remainder by horses; 14,865,936 passengers were carried—an average of 80,793 per day—and the receipts amounted to £91,590.

Electricity as a motive power thus having been introduced on the Dalkey line, which lay outside the city, and the directors of the Company having recognised its great efficiency in reducing working expenses and in enabling quicker and better services to be rendered, and notwithstanding that old-fashioned prejudices still stood in its way and that the former appeal to Parliament for powers to introduce it into the city had been unsuccessful, determined to equip with electricity under the powers of their Act of 1896 a portion of the Clontarf line, about two miles in length, on the North side of the bay and lying outside the city, and for this purpose erected a small generating station at Clontarf. This piece of line was converted and opened for electric traction on November 11, 1897. At the generating station referred to, plant sufficient to run about 25 cars was installed, and the overhead system of supply was adopted between the points above mentioned.

During the time the foregoing conversion and equipment were being carried out, negotiations with the various local authorities took place, and as the result of large concessions to them, in the year 1897 an Act of Parliament was obtained authorising the use of electric traction on all the lines of the Company; and the Directors having secured the services of Mr. H. F. Parshall as consulting engineer, an extensive scheme was devised with the intention of retaining the two existing power stations at Balls Bridge and Clontarf, and erecting a main station for the supply of all the lines not served by these two. A deputation from the directors, accompanied by Mr Parshall, proceeded to America in order to ascertain the most up-to-date methods, and there purchased the greater portion of the machinery and equipments needed. A fine site on Ringsend Dock was acquired, and the building of the main station was commenced in October, 1898. At the same time the laying of the conduits, which was entrusted to the National Conduit and Cable Co., was carried on, the feeder cables drawn in, and the poles and overhead lines erected. All this work was vigorously pushed on, the lines, as far as possible during the conversion, being worked by horses, whilst some were worked electrically immediately they were equipped from the old stations at Balls Bridge and Clontarf. The main power station was first operated on August 16, 1899, but the lines were not all simultaneously opened for electric traction, nor was the whole of the machinery in the station completed by that date; extensive reconstruction of the tracks had to be undertaken, the rail section used for horse traction being too light for the heavier cars and deeper flanged wheels needed for an electric system; but line after line was successively opened, and in the half-year ended June 30, 1900, horse traction was discarded, and practically the whole system worked by electric traction. The Company is now using for relaying its lines a rail weighing 105 lbs. to the yard, about double the weight of that originally used in the earlier years of its existence.

To provide rolling stock, the Company at their works at Inchicore converted most successfully a number of the old horse cars, and purchased others in America and from Messrs. G. F. Milnes & Co., but since these purchases were made, they have been constructing all the cars needed at their own works, and the present rolling stock comprises 314 cars, whilst six are at present under construction. A table in the Paper gives details of the cars and shows that they are fitted with trucks and equipments of various types.

The operation of the main station having proved most economical, and the two older stations being very disadvantageously placed both

* Abstract of a Paper read before the Tramways and Light Railways Association at Dublin.

Digitized by Google

as to coal and water supply, it was decided that all the power required should be generated at the Ringsend main station, and to enable this to be done, modifications were made in the existing plant, and the necessary cables were laid; the Clontarf station was converted into a sub-station, with sufficient capacity to supply, not only the portions of the lines hitherto supplied by it as a generating station, but also a new line belonging to the Clontarf and Hill of Howth Tramroad Co., practically a continuation of the Clontarf line for about five miles to Howth. The Clontarf station was closed down on February 14, 1901, and at Balls Bridge on January 3, 1901, and since the latter date the main station at Ringsend has been taking care of all the lines in a most economical manner. In the half-year ended December 31, 1901, 46·34 miles were open for service, 23,816,084 passengers carried, an average of 129,380 per day, and £128,416 earned.

At the Ringsend station the two steel stacks, each 220 ft. high, have recently been lined inside with ferro-concrete in place of the original fire-brick lining, which makes them much safer and more durable. These stacks and the framework of the buildings were constructed by the Riter Conley Co., Pittsburg. There are at present 12 Babcock & Wilcox water-tube boilers erected, but provision is made for eight more. Whilst the six engines are all by the E. P. Allis Co., of Milwaukee, and are of vertical cross-compound type, yielding each about 700 B.H.P. The generators, by the General Electric Co., are keyed on the engine shafts, five being multipolar direct current, and the sixth a 2,500 volt three-phase machine with revolving field.

Since the opening of the station, one of the engines has been fitted with a three-phase alternator in addition to the original direct current generator. This was done by removing the 31 ton flywheel and erecting a flywheel alternator in place of same. In 1907, in order to meet the largely increased alternating load due to development of traffic on the coast lines, a 1,000 kw. turbo alternator was installed, the turbine being of Messrs. Willans & Robinson's manufacture under Parson's patents, the alternator being supplied by the British Westinghouse Co. A 250 kw. rotary converter, by the British Thomson-Houston Co., is also installed, as at times it is convenient to transform certain proportions of the alternating current to direct current in this station, or vice versa. There are also four negative boosters, but since the alteration in the Board of Trade rules regarding return circuits, these have been thrown out of operation. The switchboard extends on a gallery across the whole width of the engine room, and was built by the British Thomson-Houston Co.

The sub-station equipments at Blackrock, Dalkey and Clontarf are in principle alike, differing only in capacity. That at Blackrock contains three rotary converters, each 200 kw. capacity, and nine transformers of 80 kw. each, divided into two sets of three, so that should any one of the three become disabled the other two could do the necessary work. The Dalkey sub-station contains four rotary converters, of 75 kw. each, converted by Mr. Parshall from the motor generators originally in this and in the Blackrock sub-stations, and one set of three static transformers with the necessary switchboard and instruments. The Clontarf sub-station, formerly a generating station, contains one 250 kw. B.T.-H. motor generator set, the motor being of the induction type; one 250 kw. rotary converter with a set of static transformers; and two rotary converters, which were adapted from the generators in the Balls Bridge station, and altered to the designs of Mr. H. F. Parshall.

From the power station at Ringsend a most comprehensive system of conduits has been laid. They consist of cement-lined iron pipes bedded in concrete, with manholes situated at convenient intervals. The conduits pass in a specially constructed tunnel under the Canal Dock close to the power station. Both the high-tension and feeder cables are carried in these, the cables being furnished by the National Conduit & Cable Co., of America.

For the trolley wire in the centre of the system where the traffic is heavy, No. 00 Phono-electric trolley wire is employed, as this wire has been found to give very little wear even with a fast service of cars operating, and does not become crystalline and fracture, which is one of the troubles experienced with hard drawn copper after it has been erected for some time. In outlying districts the trolley wire is of hard copper, most of it of 00 B. & S. gauge; but all copper trolley wire is anchored at each suspension after it has been in service for two years, this anchoring having proved quite effective in preventing broken trolley wires from falling in the street.

Electric Power for Dredging.—According to the "Electrical Review and Western Electrician," the American Dredging Co. have contracted with the Southern California Edison Co. for electric power to be used for dredging San Francisco harbour. A minimum amount of 12,000 H.P. is to be supplied at a minimum cost of £3,000 per annum.

THE WALBROOK TELEWRITER EXCHANGE.

Although the telewriter has been more extensively used in America than in England, the credit of inaugurating the first telewriter exchange belongs to this country. This exchange, which is at present only connected to about 50 subscribers, but contains provision for connecting up a further 750, is situated in the offices of the National Telewriter Co., Bucklersbury, London, and is being officially opened to-day by the Right Hon. the Lord Mayor of London.

Since the telewriter has been employed to a limited extent for many years in this country and the United States—a description of the Ritchie telautograph, as it was then called, was given in THE ELECTRICIAN so long ago as November 16, 1900—it is rather surprising that its use has been restricted

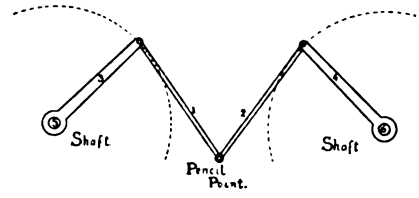

FIG. 1.

almost entirely to these two countries, the more so as the many advantages of the telewriter should appeal forcibly to certain sections of the public. As the instrument has not been prominently before our readers in recent years, it may be as well here briefly to explain the principle on which it works.

The main principle employed in the telewriter is that of producing two independent motions by the movement of the transmitting pencil, each motion causing a change of current in a circuit. At the receiving end these two varying currents produce independent motions, the resultant of which is a reproduction of the movement of the transmitting pencil.

For transforming the motion of the transmitting pencil into the rotary motion of two shafts, the arrangement diagram-

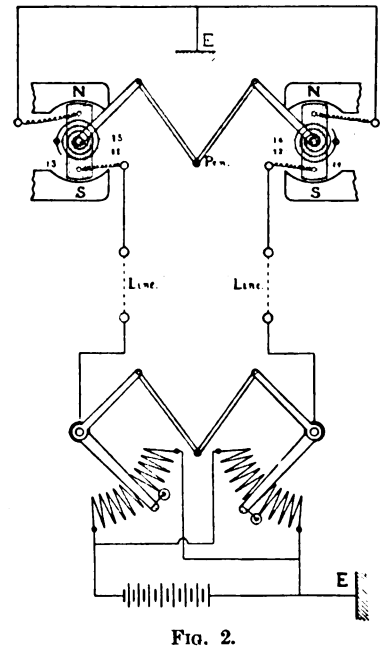

FIG. 2.

matically shown in Fig. 1 is adopted. This illustration is self-explanatory. Each of the shafts shown has rigidly attached to its lower end a lever carrying a contact roller connected to one of the two line conductors. This roller passes over the contacts of a rheostat (*see* Fig. 2), thereby varying the current flowing in the line, the earth serving as the return conductor. At the top of Fig. 2 will be noticed the receiving apparatus, the moving coils of which are controlled by springs, and take up a position in accordance with the current flowing in each circuit. By connecting the receiving pen to the shafts by a link motion

Digitized by Google

identical with that in Fig. 1 the motion of the transmitting pencil is thereby reproduced.

The paper is fed at the same instant at the receiving and sending stations, at the latter mechanically and at the former electrically. In Fig. 3 (left-hand side), which shows an interior view of the transmitter, will be noticed a finger lever O, connected at its inner end by a rod to the paper shifter P. When the lever O is moved to and fro between its stops, the paper shifter rocks to and fro and feeds paper over the platen Q at each movement. Actuated also by the lever O is a switch which, when closed, operates a relay at the receiving end and feeds the paper forward one step. The relay R (Fig. 4) also controls a circuit which includes the field magnets W, X and the pen-lifter Y.

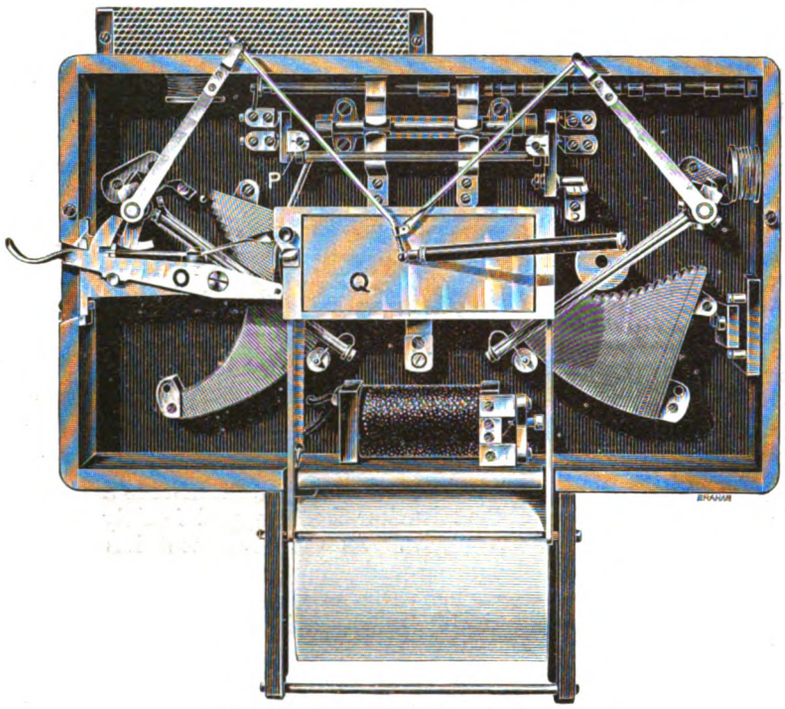

Fig. 3.—Interior View of Transmitter.

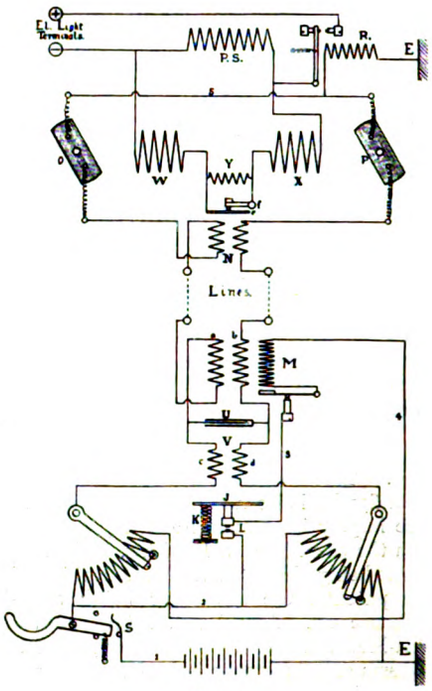

Fig. 4.

At the transmitter, movements are made both on and off the paper, and it is necessary to provide means for raising and lowering the receiving pen accordingly. This is accomplished by sending a superimposed alternating current over the lines. Referring to Fig. 4, J is the hinged platen over which the transmitter paper passes. It is held in its upward position by spring K, and is brought to its downward position by the pressure of the operator's pencil in writing. In the latter position contacts are closed at L, which completes a circuit through the break and primary winding of an induction coil, M. This coil has differential secondary windings, *a* and *b*. These are included in the line circuits, but in relatively reverse directions, so that at any given moment the induced current in one line will be in the opposite direction to that in the other; *c* and *d* are the windings of a choke coil also in the line circuits, the function of which will be referred to later. It will be seen that whenever the operator's pencil is "on" the paper the induction coil M is brought into operation, and an alternating current induced in the secondary windings is superimposed upon the writing currents passing through the lines. At the receiver this alternating current passes through the differential windings of a vibrator, N, and the moving coils O, P. The vibrator has over its core a reed, *e*, upon which rests a weighted lever, *f*, the contacts of which shunt the winding of the pen-lifter Y. When the transmitter platen is depressed, the current from the induction coil M causes the reed *e* to vibrate. This increases the resistance between the contacts of *e* and *f* to such an extent that current passes through the winding of pen-lifter Y, causes its armature to be attracted, and allows the receiving pen to rest upon the paper. When the induction coil M is inactive,

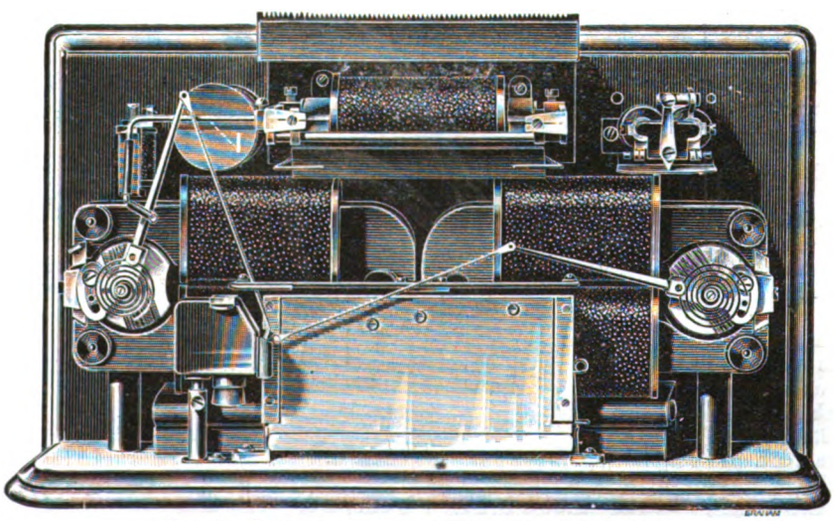

Fig. 5.—Interior View of Receiving Instrument.

Fig. 6.—Telewriter as installed on Subscribers' Premises.

Digitized by Google

the contacts of the vibrator N are at rest, forming a shunt of such low resistance that the pen-lifter Y is inert. Under this condition, a spring moves the armature of Y forward, and thereby raises the pen from the paper. To prevent disturbance in neighbouring circuits, the alternating current is confined to the lines by means of the condenser U and choke coil V. The condenser forms a path for this current, and the inductance of V prevents it passing to earth.

The receiving pen, when not in use, is held in the ink well by the rod I (Fig. 5). It is also brought to this position every time the paper is shifted, and is thus kept fully supplied with ink. The line currents are taken from a small secondary battery, which by a switch (operated by the finger lever O, Fig. 3) is connected to and charged from the electric light supply when O is in the receiving position. When the transmitter is in use this switch disconnects the battery from the lighting supply and connects it to the rheostats. The instruments are calibrated for circuits of a fixed resistance, and the lines are made up to this with added resistance.

Fig. 6 shows a telewriter in use, whilst Fig. 7 illustrates the switchboard installed at the Walbrook exchange. This is operated in identically the same manner as an ordinary telephone board, the subscribers telling the operator the number required by means of the telephone noticed hanging at the side of the instrument in Fig. 6.

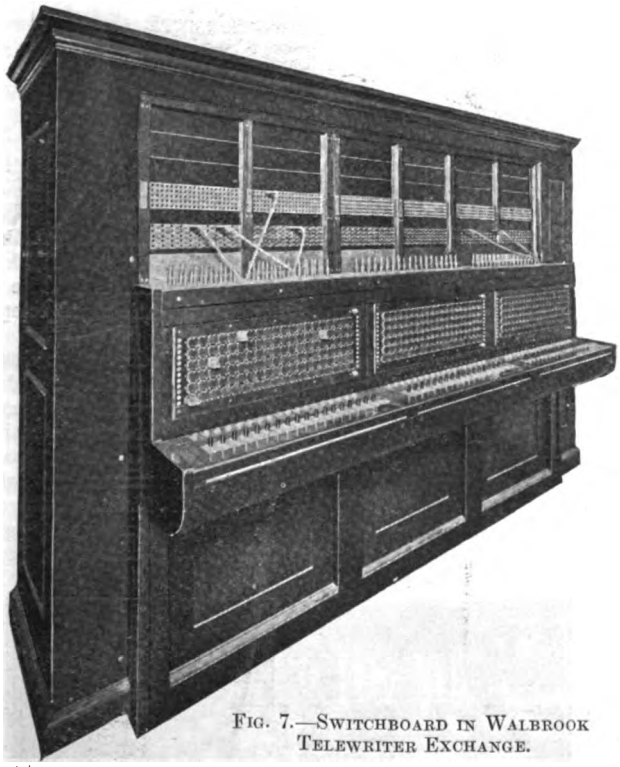

Fig. 7.—Switchboard in Walbrook Telewriter Exchange.

An important feature of the telewriter is that no attention is required at the receiving instrument, so that messages are delivered in the absence of the addressee, and are read on the latter's return. In this connection it is important to note that the first action of the transmitting instrument is to move the paper at the receiving instrument, so that a clear space is always available. It may also be mentioned that, when requested, the Post Office will arrange to forward telegrams to telewriter subscribers by means of these instruments, thus saving time in delivery. Subscribers may also send their telegrams by telewriter to the Central Telegraph Office.

As to the advantages of the telewriter, these are obvious wherever numbers and prices have to be transmitted between offices, a written record being obtained by its use; whilst a business man is able at a glance to see all those messages which have arrived during his absence, and any replies that have been given, a permanent record being thus obtained of all transactions.

We do not doubt that when the capabilities of the new exchange are widely known there will be a great accession of subscribers.

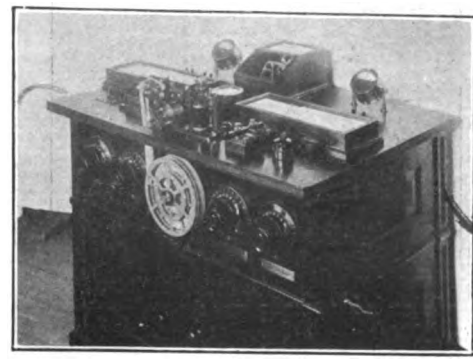
RECENT DEVELOPMENTS IN TELEGRAPHY AND TELEPHONY.*

BY SIR JOHN GAVEY, C.B.

(*Concluded from page 442.*)

Siemens & Halske, in Berlin, have devised an automatic system in which, by means of suitable apparatus, the message is printed by the receiving apparatus direct by photographic methods, an electric spark momentarily illuminating the required letter. The alphabet is stencilled on a revolving disc, and the arrangements are such that the electric spark passes only when the letter corresponding with the arbitrary signal is in the right position for printing. Figs. 1 and 2 illustrate the automatic apparatus of Messrs. Siemens & Halske.

The Western Union Telegraph Co., in America, have introduced extensively a system known as the Barclay automatic type printing



HARVARD UNIVERSITY OF CALIFORNIA

Fig. 1.—Siemens & Halske's Transmitter for High-speed Printer.

apparatus. At the sending end the code of electrical signals adopted consists of long and short intervals, either marking or spacing, representing the various letters of the alphabet. Every letter is represented by six current alternations, but the receiving apparatus is so designed that, although every current acts on an escape wheel that makes a momentary contact with certain selecting relays, only those of long duration effect any movement in the latter. There are 32 printing magnets which act as the keys of a typewriter, and cause the message to be printed direct on the receiving instrument.

Although any one of the systems described or referred to can be made to do excellent work, the actual selection of the apparatus best calculated to meet the requirements of any country depends entirely on local conditions. To what extent uniformity of practice

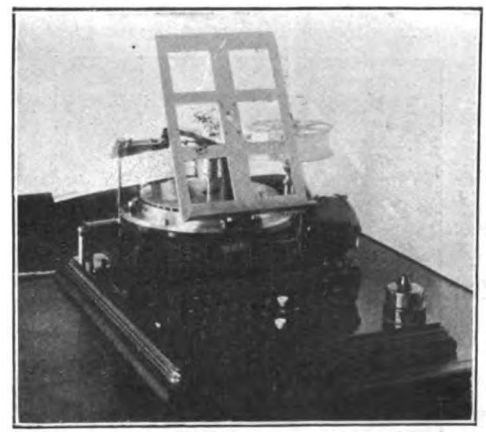


Fig. 2.—Siemens & Halske's Keyboard Perforator.

is likely to arise in the future is a doubtful question, as each country is likely to progress on the lines which have been firmly established as best adapted to its wants.

Writing telegraphs, based on the fact that two ordinates at right angles to one another can be made to describe any curve, have been designed. The telewriter is well known. At the receiving end two pivoted electromagnets, placed in a very powerful magnetic field, are deflected over arcs dependent on the strength of the current circulating at any moment. Two arms at right angles to one another are connected to the transcribing pen, one arm being pivoted to each magnet and the writer's movements are reproduced.

* Abstract of the "James Forrest" Lecture, delivered last week before the Institution of Civil Engineers.

In the beautiful writing apparatus designed by Pollak and Virag a slip is perforated by suitable means with nine rows of holes of varying sizes. Suitable flexible brushes make contact through these holes between batteries and the line wires, and thus cause currents of different E.M.F.s and duration to circulate over the line, and to act on two telephone receivers at right angles to one another. Rays of light are reflected from one to the other and on to a photographic slip, and the written messages, which can be transmitted at 600 to 1,000 words a minute, appear developed and fixed on the sensitised paper, which emerges from the dark closet of the apparatus.

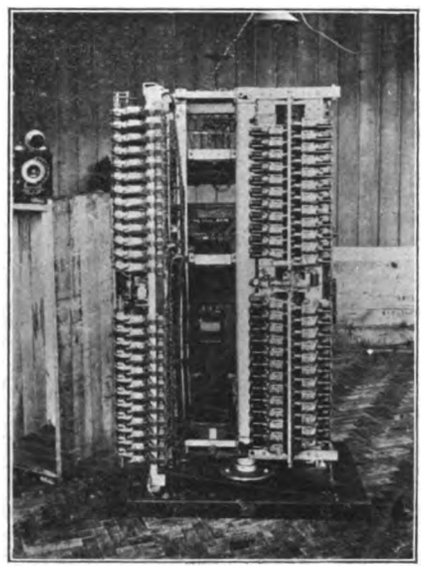

FIG. 3.—UNIT OF 100 LINE SWITCHES (HALF OPEN), AUTOMATIC EXCHANGE.

There are numerous type-printing instruments for the distribution of news, which, however, are so well known that further reference to them is unnecessary.

The effect of conductor-resistance, electrostatic capacity, self-induction and insulator-resistance (or its reciprocal leakance) was next discussed by the lecturer. Overhead wires, for many years almost exclusively used for telegraphy, and even now the only conductors that serve satisfactorily for really long-distance telephony, possess the advantages of low resistance, which can be diminished to any reasonable degree by the use of copper and by increasing the size of the conductor. Their electrostatic capacity is small, say from 0·013 to 0·014 mfd. per mile, and their self-induction is relatively great. Their use admits of attaining the maximum speed in telegraphy; and perhaps the most important limiting factor in this case

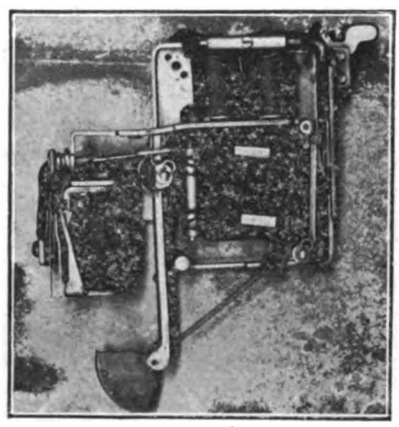

FIG. 4.—AUTOMATIC EXCHANGE LINE SWITCH.

is the self-induction of the receiving apparatus, which would be a useful factor if distributed over the line, but which tends to act as a choking coil when massed at the extremity. This self-induction in the case of the Wheatstone receiver amounts to as much as one henry, and its effect in prolonging the current, combined with that due to the capacity of the line, is neutralised to some extent by inserting a shunted condenser between the instrument and the earth.

Overhead telegraphs are subject to serious interruptions. But on the other hand, until recently, underground wires, owing to their capacity, which reached 0·3 mfd. per mile when insulated with gutta percha, and the great cost of the material, were only used in special cases where strategical or other imperative reasons rendered such a course necessary. The introduction of dry paper as an insulating material profoundly modified the situation. The electrostatic capacity of suitable paper is not very much greater than that of air, and wires wrapped with paper, cabled, thoroughly dried and enclosed in a lead sheath are not only available for long underground telegraphs, but it is not too much to say that without them the modern development of the telephone would have been wholly impossible. The Post Office has within the last few years laid 138,000 miles of paper insulated wire underground for telegraph purposes alone, and to illustrate the bearing of this material on telephone progress it may be added that, between 1900 and 1902, before a single subscriber had been secured, the Post Office laid 240,000 miles of wire underground as the first step in the development of the London system. The

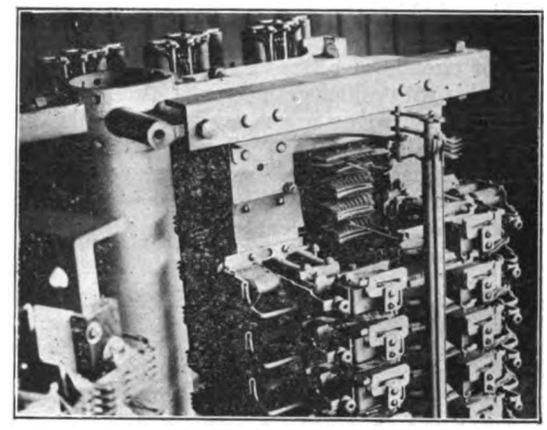

FIG. 5.—LINE SWITCHES WITH BANK OF SPRINGS, AUTOMATIC EXCHANGE.

mileage of underground wire laid by the Post Office in Great Britain for telephones is now increased to 521,000 miles. By no other known means could such a service have been provided, and these facts emphasise the connection between paper insulation and telephone development.

Submarine telegraphy is not susceptible of the many developments that have been possible with land-lines. The high electrostatic capacity, varying from 0·3 to 0·4 mfd. per mile, and the very long lengths that are necessary to connect the great continents of the world, rendering the use of any but the most delicate apparatus impossible on long cables. The receiving instruments originally invented by the late Lord Kelvin, then Sir William Thomson, are still the only apparatus available for the reception of messages on long transcontinental cables, and so far it has not been found possible

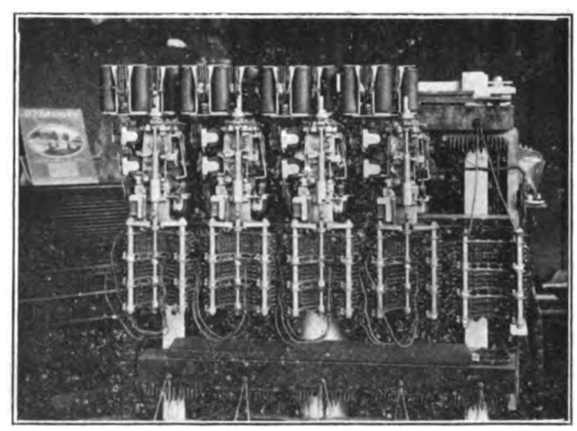

FIG. 6.—GROUP OF CONNECTORS, AUTOMATIC EXCHANGE.

materially to increase the speed of working except, of course, by increasing the dimensions and cost proportionately. Attention has been devoted to eliminating disturbing elements and perfecting the signals by the use of automatic transmission and by the use of curbing devices at the receiving end. The introduction of repeaters at intermediate points where cables land at suitable localities has recently become possible, and it may be that methods of distributed induction may ultimately be of some value.

In ordinary telegraphy when transmitting through an overhead line the frequency of the current alternations is only 180 per second

for 450 words per minute, and the current has actuated the apparatus at the further end before the battery connection has ceased. Another condition, however, is introduced when a conductor is used for telephonic speech in which a maximum frequency of 1,800 to 2,000 vibrations per second has to be dealt with. In these cases the transmission from the telephone assumes complex wave-forms, and the effect of even a moderate capacity becomes far more marked than in the case of telegraphic transmission. If the capacity be

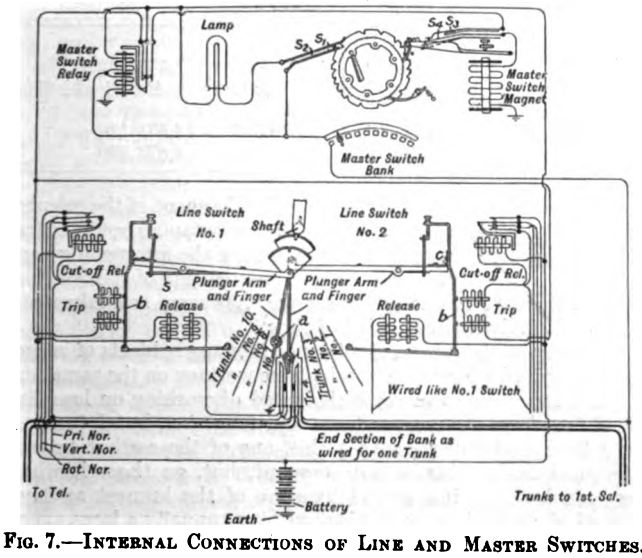

FIG. 7.—INTERNAL CONNECTIONS OF LINE AND MASTER SWITCHES.

sufficiently great and the line sufficiently long, the following wave overtakes the lagging tail of the previous one, they blend more or less together, and having lost their distinctive character they fail to impress on the receiving telephone the distinct character of the sound from which they emanate. A few years ago I had, in conjunction with the Engineer-in-Chief of the National Company, Mr. Gill, to fix certain standards of speech which had to be maintained by the two administrations working the telephone system in this country, and after a series of practical tests, which were found to accord most closely with theoretical calculations, we found the results shown in the accompanying table to represent the practical limits of ordinary commercial speech on various classes of conductor, both overhead and underground, when no special steps were taken by artificial means to overcome the deleterious effects of capacity. By endowing a circuit in which an electrical wave was in movement with sufficient self-induction to prevent the tailing and consequent distortion of the wave, the limit of speech would be materially increased, as the attenuation due to resistance alone would have to be provided for. The British Post Office has recently laid a cable with distributed inductance between England and France which will increase the range of speech about four times as compared with a similar type of unloaded cable.

The problem of connecting two subscribers' lines at an exchange is a very simple one when a small number of subscribers only are concerned. An electrical indicator of the shutter type to announce a call, flexible conductors to connect any two lines by means of plugs and spring jacks, electrical bells to call up subscribers, and the equipment is complete. The problem is a serious one, however, when, as is now the case, the number of telephone subscribers in a

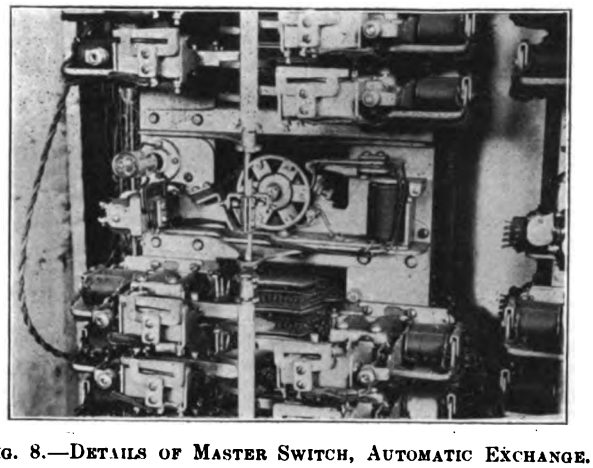

FIG. 8.—DETAILS OF MASTER SWITCH, AUTOMATIC EXCHANGE.

large city runs into five or frequently six figures, when the area covered, like that in London, amounts to 640 square miles, when it has to be served by 60 to 100 separate exchanges, between all of which intercommunication must be provided with the minimum amount of delay. Add to this the interurban communications between all the principal cities in the country, and the fact that practically the major part of the business of the 24 hours is concentrated in about 2½ hours in the morning and a similar period in the afternoon, and the difficulties to be solved become faintly apparent, even to the uninitiated.

Apart from minor improvements in the calling indicators and other details, each of which added its quota to the gradual perfection of the service, perhaps the most marked advance that was made, when exchanges grew in size, was the introduction of the so-called multiple switch. Before its introduction, each operator had the care of, say, 100 subscribers whose lines terminated in front of her. She could connect any two of these 100 directly, but as soon

Digitized by Google

as a connection had to be made to another position a subsidiary junction line had to be brought into use and the services of another operator invoked to complete the connections. To obviate this difficulty as the number of positions and subscribers increased, the multiple switch was designed. The lines of, say, 100 subscribers are then terminated on one operator's position; but on a large panel above these local jacks the whole of the 10,000 or more lines are connected to a series of jacks within reach of the operator, and this is repeated at every operator's position, so that a line on any position can be directly connected with any of the other lines on the exchange by the operator who answers the call.

A further improvement was the "common battery system." In this, the form of manual exchange equipment now considered the most satisfactory, the shutter indicators are replaced by glow-lamps placed immediately over the jacks. When a lamp lights it indicates a call, and the operator, without doubt, hesitation or delay, forthwith inserts the answering plug into the jack. At the subscriber's office no special calling apparatus is needed. The lifting of the telephone from the hook automatically lights the lamp. The electrical energy in common battery systems is provided by accumulators at the exchange, instead of by primary batteries at each subscriber's office, and not only is the cost of the exchange infinitely small as compared with the old system of providing separate batteries for each subscriber, but the further advantage follows that the full energy is always maintained and available on every circuit, a condition almost impossible to fulfil even under the best organisation when thousands of primary cells scattered over a great city have to be looked after by linemen. Similar automatic arrangements are in use on the junction lines connecting the various exchanges necessary for the effective service of large cities.

In the period during which the ordinary telephone equipment has undergone the above modifications, inventors have turned their attention to the design and perfection of an automatic telephone in which each subscriber, by a simple method of manipulation, may, without the intervention of an operator at the exchange, obtain direct access to any other subscriber connected with the service. One of the earliest systems of this type was known as the Strowger, and by the courtesy of the Automatic Electric Co., of Chicago, the owners of the patent rights, and of the British Insulator and Helsby Co., of Prescot, the lecturer was able to illustrate the working of the system. Each subscriber's line terminates on a line switch which forms part of a group of 100 switches. This switch is connected by ten circuits, the equivalent of the plugs and cords in a manual board, with a series of selectors each accommodating 100 junction lines. According to the size of the exchange there may be two or three sets of selectors connected similarly by means of junction circuits, and finally, there is a connector, a somewhat similar instrument, which makes the connection between the two subscribers. Each telephone has a dial with finger holes and numbers. On removing the telephone from the hook the procedure is as follows: If, say, No. 4852 is wanted the caller inserts his finger in hole 4 and revolves the dial up to the limiting stop. This actuates the line switch which causes a connecting plug to enter the springs of the first disengaged junction leading to the selector group of 4000. The same action follows in sequence with 8, 5 and 2, the final movement of the connector making the connection if the required subscriber is disengaged. If he be through to another, a busy back signal (a vibratory current) is given. When the connection is made and the conversation is complete, the hanging up of the telephones restores the connections to the normal. This method has had considerable development amongst the independent telephone companies in America. Figs. 3 to 9 show various parts of the equipment.

With giant strides, telegraphs, both land and submarine, have shown remarkable growth in the intervening period of five years, notwithstanding the keen competition of the telephone. The great increase in the latter service, however, has taken place within a relatively limited period of time.

On the subject of the future development of telegraphs and telephones, few of those acquainted with the subject would venture to dogmatise, but certain statistics I have prepared will convey to you possibilities far more pregnant than any amount of speculation. The following figures, for the years 1902 and 1907 respectively, have been gathered from authentic returns, and they embrace information from every country of importance throughout the world.

Telegraph and Telephone Statistics.—Wire Mileage.

——	1902.	1907.	Increase.
TELEGRAPHS.			
Land wires	3,659,659	5,038,981.	1,379,322
Submarine cables .	212,894	259,000	46,106 = 21·6%
TELEPHONES.			
Wire	7,467,417	19,839,537	12,372,120
Subscribers' stations	3,534,036	8,406,336	4,873,330

It will be observed that although the development of the telephone service is taking place with giant strides, telegraphs, both land and submarine, have shown remarkable growth in the intervening period of five years, notwithstanding the keen competition of the telephone. The great increase in the latter service, however, has taken place within a relatively limited period of time.

Time does not admit even of reference to many subjects of interest, such as combined telegraph and telephone working on the same wires, the use of repeaters to increase the speed of working on long lines, modern fire-alarm systems, railway signalling, &c., but I trust that what I have said will show that this, one of the earliest branches of electrical engineering, is not stagnant, but, on the other hand, is very much alive; it is served by some of the keenest and most advanced of electricians, and it is absorbing annually a large amount of capital which it is turning to good and profitable use.

Brief reference was finally made by the lecturer to wireless telegraphy, the work of Marconi, Poulsen and Lepel being specially mentioned, and a number of ship and station equipments being illustrated. By substituting a telephone transmitter for the ordinary telegraphic key, it has been found possible, the lecturer said, to transmit actual speech a distance of 30 or 40 miles, whilst the limit of wireless telegraphy may now be placed at perhaps 5,000 miles.

Rail Corrugation.—In referring last week to the interesting pamphlet on this subject which has been prepared by Mr. J. H. Briggs, the inadvertent use of the word "this" for "the" in the 13th line of our note made it appear as if friction from any cause would result in chattering, whereas Mr. Briggs in his pamphlet shows that the chattering can only arise from throat friction resulting from the downward motion of the leading outer wheel.

ELECTRIFICATION OF THE CENTRAL ARGENTINE RAILWAY WORKSHOPS.

The Central Argentine Railway Co.'s locomotive, carriage and waggon works at Rosario de Sante Fé cover an area of 110 acres and give employment to about 3,500 men. They are equipped with every description of plant necessary for the construction and repair of railway rolling stock, and practically the whole of the rolling stock for this important railway, with the exception of the actual construction of

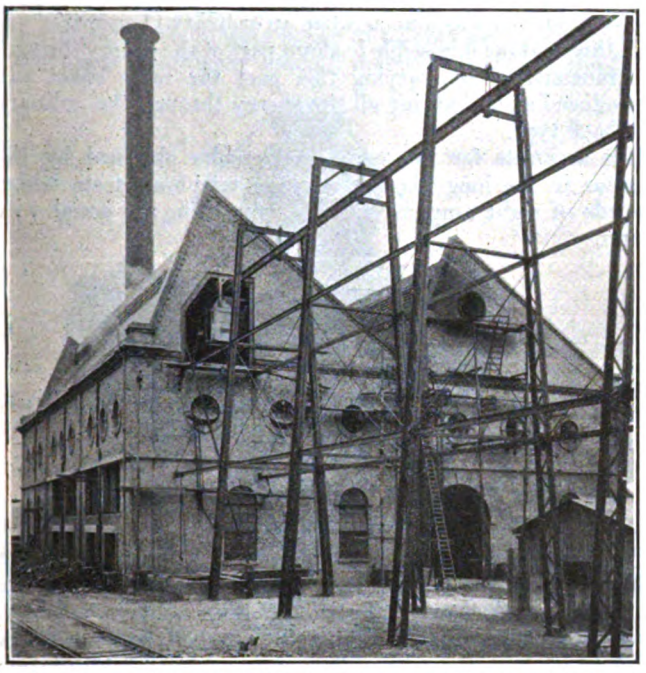

Fig. 1.—Power Station of Central Argentine Railway Workshops.

locomotives, is turned out by these works. At present about 165 locomotives, 725 passenger coaches and 6,100 waggons pass through the shops for repairs in the course of a single year, in addition to an annual output of new stock of about 60 passenger coaches, including dining and sleeping cars, and 1,500 waggons, chiefly of the covered type of from 18 to 40 tons capacity.

In 1906 important extensions were in contemplation, and it was decided to convert the whole of the works for electric driving, and also to supply, from the same central station, power and lighting to grain belts and elevators (having a frontage of about 1½ miles on the river Parana), to a sawmill situated about a mile from the shops, and to two terminal passenger stations and the extensive goods and sorting yards in Rosario. The British Westinghouse Electric & Mfg. Co. secured the contract for the plant and equipment.

The power station (Fig. 1) is situated practically at the centre of the works, and measures 116 ft. by 91 ft. 6 in. The boiler room contains four Babcock & Wilcox boilers, each having a heating surface of 5,764 sq. ft., and an evaporative capacity, when burning coal, of 20,000 lb. per hour, the steam pressure being 185 lb. per square inch. Integral superheaters, capable of superheating the steam up to 150°F. at the boiler stop valve, are fitted. Hand-fired grates were adopted with a view to burning sawmill refuse, but overhead steel coal bunkers, of a storage capacity of 200 tons, have been installed, the coal being taken direct from the waggons by a telpher. The ashes are removed from the ash cellar below the firing floor to an outside pit, whence they are picked up by a telpher.

The economiser and pump room adjacent to the boiler room contains a Green's economiser of 480 tubes arranged in two halves, with the usual by-pass flue underneath, three Hall steam-driven compound feed pumps of a capacity of 4,000 gallons per hour each, a Kennedy hot-water meter and a Rankin filter and Row's patented feed water heater. The steel chimney is of the self-supporting type, and rises to a height of 150 ft. above the base, with a diameter of 8 ft. inside the fire brick lining, this lining being carried right through to the top. A forced draught fan has been provided for increasing the draught when burning sawmill refuse. A single main with sectioning valves serves the whole of the boiler room, the engine branches being taken from this through the partition wall. The feed pumps, &c., are supplied from an auxiliary main parallel to the main header. A ring feed main is carried along the front of the boilers, each piece of apparatus in the feed system being provided with a by-pass.

The plant already installed in the engine room (Fig. 2) consists of three 500 kw. and one 200 kw. Bellis-Westinghouse sets, foundations being provided for a fourth 500 kw. unit. The engines are triple expansion, working with steam at 180 lb. pressure at the stop valve, and having a speed of 300 and 375 revs. per min. respectively. Exhaust is to atmosphere at present, but provision has been made for the addition of surface condensers should these subsequently be found desirable. The generators are three-phase 550 volts, 50 periods, and each, with its engine and separate exciter, is mounted on a combination base-plate. Motor generators, each of a capacity of 150 kw., are installed for providing direct current at 440 volts for overhead cranes and surface traversers. High-tension transmission has been adopted for power and lighting outside the works, and six single-phase 125 k.v.a. 550 to 3,300-volt step-up transformers are installed in the basement.

The switchboard galleries extend along the greater part of the length of the engine room, the low-tension and direct-current board being situated on the lower and the high-tension gear on the upper gallery. The low-tension board includes generator, low-tension feeder, direct-current feeder, transformer, load and motor-generator panels, while the high-tension board consists of six transformer and seven feeder panels. All the alternating-current switches are of the oil-break type, and those on the generator and feeder panels are provided with overload and time-limit relays. Each of the 25 feeders is provided with choking coils and lightning arresters and has also its own integrating wattmeter, so that the consumption of each department may be recorded. Isolating plugs connect the high-tension switches to the 'bus bars; the withdrawal of these plugs isolates any panel from the rest of the board. The outgoing feeders are, with one exception, carried overhead. They consist of hard-drawn stranded conductors with a weather-proof covering. A 10-ton three-motor overhead crane, also fitted with hand motion, runs the length of the engine room, and the usual auxiliary apparatus, store-rooms, offices, &c., make the station up-to-date in every respect

Group driving has been adopted in the larger portion of the fitting and turning shops, but in the sawmills and other departments, as well as for the large tools, such as wheel lathes, the individual drive is general. The motors, which are of both the squirrel-cage and the slip-ring type, range in size from 2 H.P. to 150 H.P. Up to the present about 160 motors, aggregating some 2,600 H.P., have been put to work. These figures will, we understand, be considerably increased when the extensions now in progress are completed.

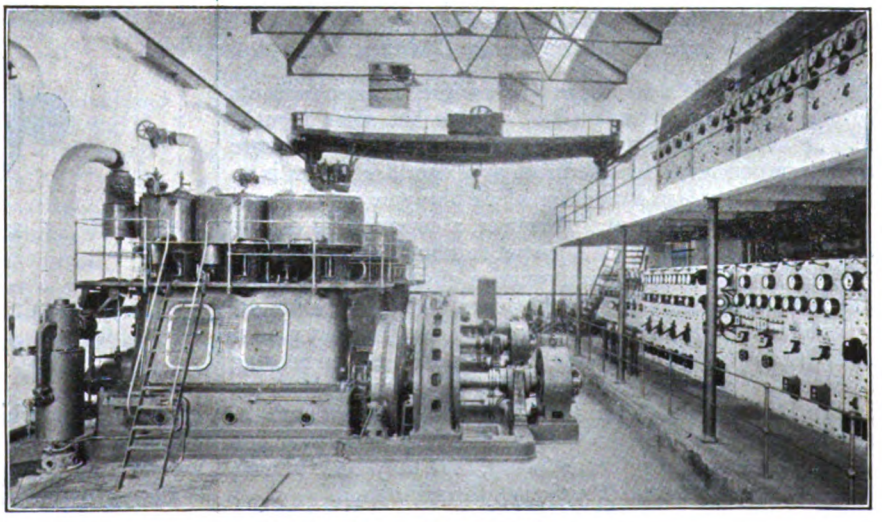

Fig. 2.—View of Engine Room.

The wiring, except in the case of the sawmills, where screwed iron barrel has been largely adopted, is by means of open insulator work. The distribution boards have one main switch with fuses on the separate motor circuits, an additional switch and fuse being mounted near each motor. The lighting circuits are supplied from 550 to 220-volt step-down transformers, an intermediate tapping being provided in the low-tension side of the latter for 110-volt arc circuits where these

Digitized by Google

are desirable. Flame arc lamps have been installed in the majority of cases, but enclosed lamps have also been installed where they have appeared more suitable. Seven transformer sub-stations are at work, or in course of construction, at various outlying points, for the supply of light and power to the grain elevators, sawmills, stations, &c., already mentioned, and when the system is completed the power and lighting arrangements of the Central Argentine Railway at Rosario will be at least as up-to-date as those of any system in the United Kingdom.

The electrification may, we gather, be said to be an unqualified success. The cost of power has been reduced and the output of the shops has been increased. Piecework prices—which form the larger part of the wages bill—have been considerably reduced without lowering the earning capacity of the men. These results have, of course, in some cases been obtained by increased speeds.

The plant was supplied to the specification of the railway company's consulting engineers, Messrs. Livesey, Son & Henderson, and erected under the supervision of the railway company's mechanical engineer, Mr. Harry Pearse, by the British Westinghouse Electric & Mfg. Co.

A NEW WIRELESS TELEPHONE TRANSMITTER.

BY WILLIAM DUBILIER.

In almost every transmitter thus far conceived the action is produced by the variations of pressure on loose contacts, but the limit is soon reached with the ordinary transmitter in regard to the amount of energy it will carry. Many difficulties arise when large amounts of energy are utilised. In order to overcome this difficulty several attempts have been made to

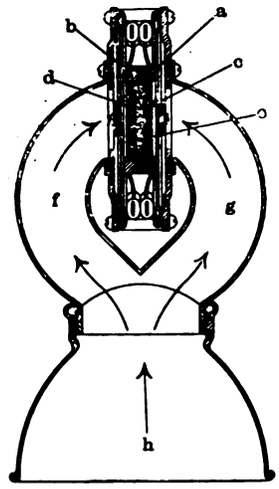

Fig. 1.—Cross-section of Collins Transmitter.

obtain a stronger effect or change by a number of loose contacts or several diaphragms being effected from the same mouthpiece. In all these cases, however, it was found that where more energy can be varied distinctness is sacrificed, that is to say, where we increase a number of diaphragms we decrease the clearness of articulation. However, a compromise can be made between the two, and if a proper combination is obtained better results can be had than when a single transmitter is used. In all these combinations, however, and in fact in almost every transmitter yet designed the contacts are generally placed behind the diaphragm, and consequently only the increasing and decreasing of pressure on the side of the diaphragm are utilised. In the solid back transmitter a large amount of energy is lost due to the vibrations of both the diaphragm and the back in synchronism, that is to say, that they both vibrate to and fro and in the same direction at the same time.

From this it can be readily reasoned that a large proportion of the vibrations or variations is wasted. Many attempts have been made to overcome this loss, utilising the vibrations of the diaphragm in both directions by constructing double acting microphones, but none of these instruments have come into general use.

Many transmitters have been constructed with several diaphragms, but all of these seem to have the drawbacks mentioned above and tend to make speech inarticulate. In the new transmitter here shown Mr. A. Frederick Collins, the well-known inventor in the field of wireless telephony, has tried to combine in an instrument large volumes of energy and variations of these volumes to such an extent as to make the transmission of speech clear and articulate. With this new transmitter the objection stated above, namely, that in a solid back type the solid back vibrates in unison with the diaphragm, thus decreasing the amplitudes of the variations, is eliminated. Further, the effect of the amplitude of the variations is increased to such an extent that in many tests the voice was received four times as loud as when an ordinary transmitter was used, thus making it possible to shunt part of the energy through the transmitter; by varying this part the same effect can be produced as by varying all the energy through the ordinary solid back type.

This accounts for the very good results obtained by the inventor in his long-distance wireless telephone tests where upwards of eight amperes have been used in the aerial wire system.

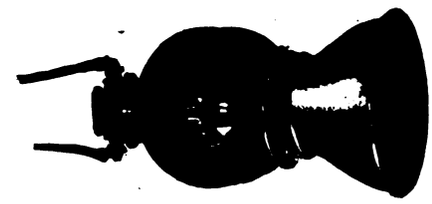

Fig. 2.—General View of Instrument.

The construction of the instrument is as follows: Referring to Fig. 1, the two diaphragms *a* and *b* oppositely disposed are rigidly held on the brass frame so that they can vibrate freely. Upon these are screwed the finely polished carbon surfaces *c* and *d*, which form the sides of the cavity containing the carbon granules shown in *e*. These granules form the loose contact between the polished carbon surfaces. To the centre of the brass frames are screwed the tubes *f* and *g* which lead around to one mouthpiece *h*. The vibrations are divided up in *f* and *g*, and act on the diaphragm in opposite directions, thus causing these diaphragms to act simultaneously against and away from each other. Thus it may be seen that instead of a single diaphragm vibrating and compressing the carbon granules we have two diaphragms operating against each other and on the same granules, producing an amplitude of variation far in

Fig. 3.—Water-cooled Type.

excess of that which can be accomplished with a single diaphragm. Fig. 2 is reproduced from a photograph of the instrument.

Many combinations of these instruments have been tried with surprisingly good results. Mr. Collins has constructed a transmitter with the granular holder cooled by a flow of water (Fig. 3), and with this arrangement it has been in constant operation for 12 minutes, allowing the high frequency current to pass through it; this current indicated 4 amperes on the meter placed in series with the aerial. During this test there were little variations in the clearness of articulation from the first to the last second, and the experiment proved that the instrument can be used for almost any reasonable length of

Digitized by Google

time. As patents are being applied for, the details of construction of the water-cooled type cannot be given at present.

Another experiment was successfully tried with four transmitters connected in parallel and directly in series with the aerial wire system. When the Collins revolving oscillation arc (described in THE ELECTRICIAN of March 4th) was used on this system, currents as high as 15 amperes were obtained. The four transmitters connected in parallel were placed in series with the earth, and used continuously for over 15 minutes for making tests. During this time articles from various technical papers were read and recorded at the receiving end, and, when compared, there were found to be only four mistakes out of two pages of ordinary reading matter. In Fig. 4 the four

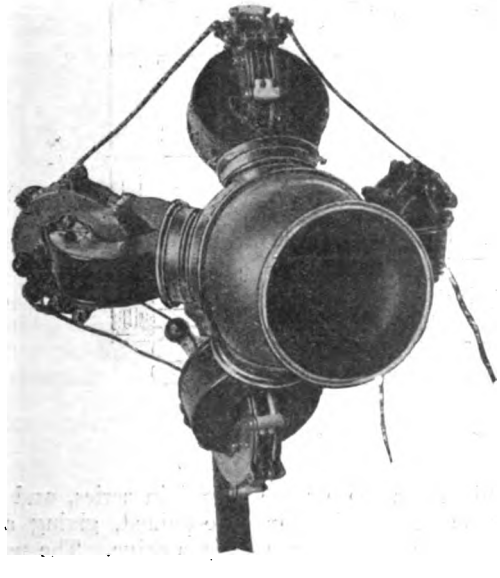

FIG. 4.—FOUR TRANSMITTERS IN PARALLEL USING A SINGLE MOUTHPIECE.

transmitters are shown with a single mouthpiece; due to the construction, this combination is equivalent to eight of the solid back transmitters.

Long distance wireless telephone tests will be made before long with this microphone, and from the results already obtained it is believed that the record for telephony will be broken, wire or wireless.

THE DAIMLER "K.L.P." PETROL ELECTRIC OMNIBUS.

An interesting type of petrol electric omnibus, embodying several novel features, has recently been developed by the Daimler Co. under the patents of Knight, Lanchester and Pieper, whence the abbreviated title "K.L.P." The principal points aimed at in the design are reduction in weight, with a minimum of unsprung parts, simplicity and accessibility of the mechanism and simplicity of control.

The novelty starts with the chassis, in that there is no chassis as ordinarily understood, the frame being formed of the bottom or well of the body. This is built up of sheet steel rolled into a deep channel section (Fig. 4) the whole width of the base of the body. At the points of load application on the springs, cross members shaped and riveted to the steel well are fitted, these adding the necessary stiffening at the points required. To obtain torsional rigidity to meet all winding and twisting strain on the frame a large rectangular steel tube is fitted in between the two sides of the steel well under the driver's seat and firmly riveted to it. This member also forms the petrol tank, and has a capacity of 25 gallons.

At each side of this sheet steel frame, and under the top horizontal webs or seat line, are fitted the power units (Fig. 2). These on the present omnibus comprise two four-cylinder. 12 H.P. (R.A.C. rating) engines of the new Daimler "silent Knight" type, the crankshafts and frames of which are extended, and on this the motors are fitted, the whole forming complete and compact self-contained units. Each motor, which is a shunt-wound six-pole machine, is nominally rated at 3 kw., but has a "give and take" capacity of three to four times this rating. The drive from each unit (Fig. 1) is taken directly from the engine and motor shaft to a worm drive fitted to each wheel through a tubular cardan-shaft, no differential gear being used.

Built up directly on the sheet-steel frame is the body, the framing of which is made entirely of sheet steel; the side posts come straight down from top to bottom, no reduction of width taking place, thus giving a base at bottom the full body width. A battery of Tudor accumulators is carried, and the motors can act as motors or generators as required. At times of light running the motors act as dynamos, and charge the battery, but when the load is heavy the battery supplies power. Reversal is effected by the motors alone, and thus the usual change speed and reversing gear is eliminated.

The road wheels are mounted on the extremities of a tubular cranked axle tree, and are driven by short live axles coupled direct to the worm wheels on the right and left-hand sides of the vehicle respectively. The axle tree is so designed that each road wheel and the worm gear by which it is operated are carried directly off the spring bracket—that is, the portion of the axle tree directly supporting the weight of vehicle.

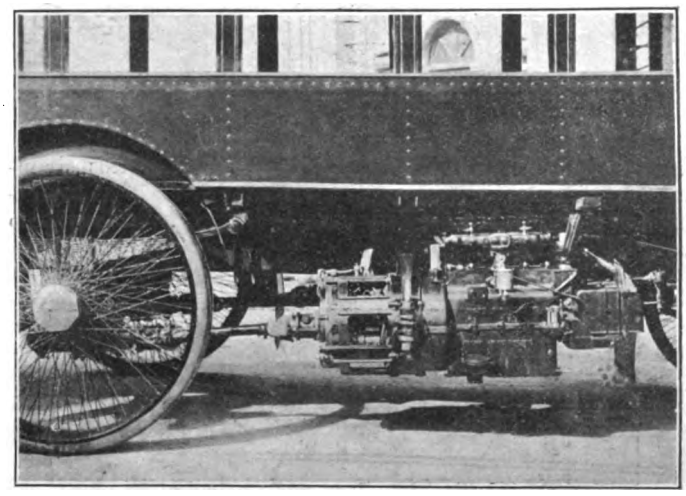

FIG. 1.—ONE OF THE PETROL ELECTRIC SETS WITH COVER REMOVED.

Between the wheel and worm casing are fixed the rear springs, and, as can be seen, this method of construction enables a maximum spring base to be used, the spring requiring to clear the wheel rims only.

In view of the fact that one of the principal objects in design has been to reduce weight to a minimum, the employment of wheels of a larger diameter than hitherto used might appear a retrograde step; but by the employment of specially designed suspension wheels it has been possible to use 40 in. diameter wheels on the front axles and 48 in. diameter wheels on the rear axles; and, besides obtaining the great advantages due to large wheel diameters, not only have the weights of the wheels been reduced, but it is stated that a much larger factor of safety has been obtained.

The unsprung weights have been reduced to a very low figure, that below the rear springs being somewhat under 10 cwt. and below front springs being about 5 cwt., as compared with weights on other makes varying from 5 to 7 cwt. on front axles and 16-23 cwt. on rear axles.

By the disposition of mechanism adopted, the height of the platform inside the body above the ground has been reduced to 27 in., this being 5 in. to 10 in. lower than the majority of existing types; also a ground clearance has been increased, being made equal to the axle clearance. This, with the large wheels employed, amounts to 15 in., against 10½ in. minimum specified in the police regulations. The power units are slung in the track of the wheels, hence their ground clearance does

Digitized by Google

not enter into consideration; however, even here a 12 in. clearance is given.

The battery and switchboard are carried underneath the driver's seat.

Front wheel brakes are provided, and four separate methods of braking are possible:—

(1) By bringing the lever on the steering wheel to strongest field position, when the momentum of the omnibus is absorbed by charging the battery; (2) by magnetic brake operating on both cardan-shafts actuated by one foot pedal, this simultaneously de-clutching the engines; (3) by a foot lever operating the brake on front wheels; and (4) by a hand lever also actuating front wheel brakes.

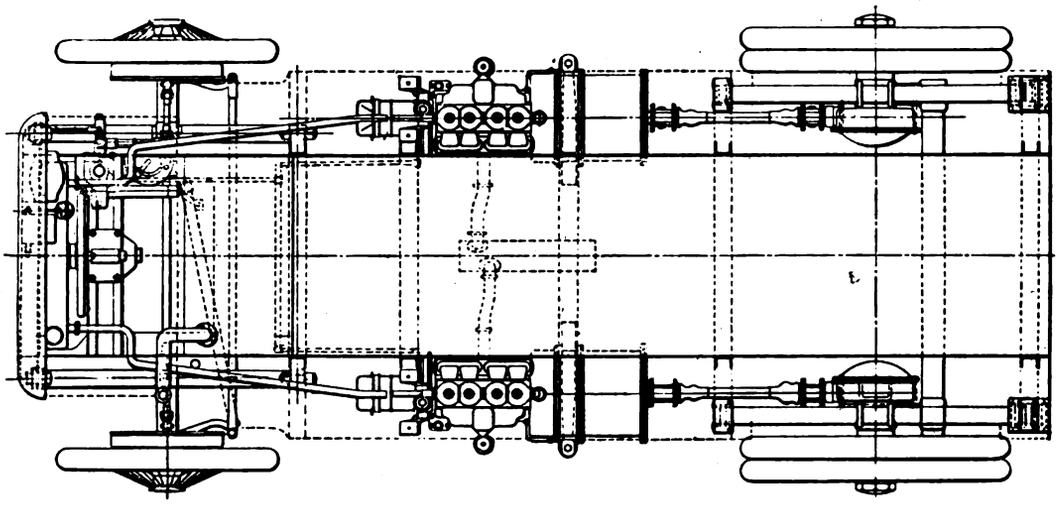

FIG. 2.—GENERAL ARRANGEMENT OF ENGINES AND DRIVING GEAR.

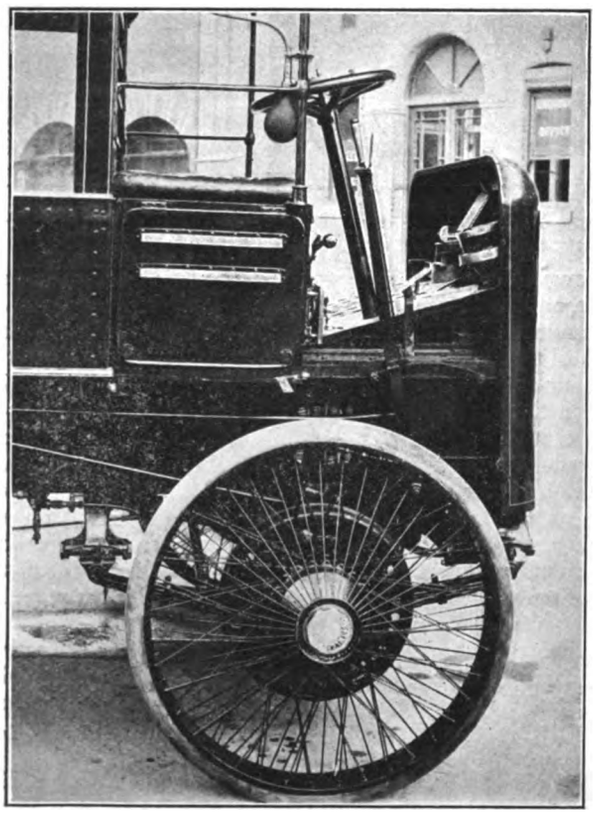

FIG. 3.—SHOWING THE CONTROL.

For the control of the omnibus there are two levers, placed on the top of the steering wheel—one connected up to the motor field controller, this lever entirely controlling the speed, which varies between 3 and 14 miles per hour; the other is connected to the two engine throttles. For running in a forward direction the two motors are in parallel with the battery; the field regulation is controlled by a common rheostat.

An automatic arrangement is provided to prevent overcharging of the battery. This consists of a solenoid device, which, when the battery voltage exceeds a certain value, acts upon the throttle levers, reducing the speed of the petrol engines. Conversely, if the voltage falls below a certain value, the speed of the petrol engine is automatically increased.

For reversing, the motors are placed in series, and so an efficient low-speed combination is obtained, giving a high torque and a perfectly balanced reverse drive. The parallel-series position is obtained by a single controller, the operating lever for which is within easy reach of the driver, but is not touched by him until change of direction is required. The magnetic brakes and clutches on both power units are in parallel with a single controller operated by a pedal.

The radiator, placed in front of the vehicle, is connected with both engines, the circulation pump serving both units in common. The pump is driven by a small ½ H.P. electric motor,

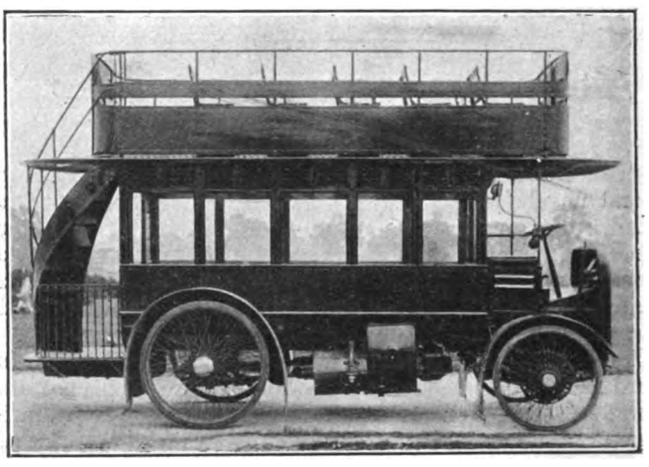

FIG. 4.—GENERAL VIEW OF DAIMLER PETROL ELECTRIC OMNIBUS.

this also driving a fan of ample capacity arranged in the customary position behind the radiator.

The total unladen weight, including 5 cwt. of accumulators, complete ready for the road, is 3 tons 9 cwt., the police regulations allowing 3 tons 10 cwt. There is seating accommodation for 34 passengers.

Fig. 2 shows the general arrangement. In Fig. 1 one of the detachable sets is shown with cover removed, whilst in Fig. 3 the simplicity of the control is apparent. A general view of the omnibus is seen in Fig. 4.

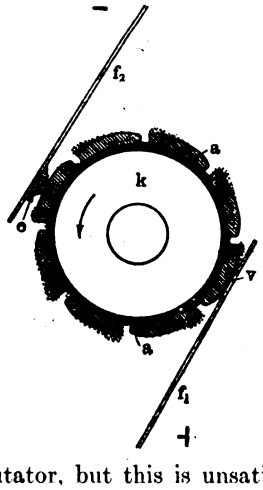
SOME NOTES ON METERS OF THE THOMSON-HOUSTON TYPE.*

BY PAUL MAY.

The Thomson-Houston meter owes its present position to the simplicity of its construction and its low price, although it must be admitted that its rivals have many good points. The more complicated types will work for six or seven years without any repairs; the Thomson-Houston meter, however, requires to be carefully examined and cleaned at least every two years, and sometimes oftener. The commutator and brush collectors usually require cleaning, but other parts are often found to need adjustment. A fresh meter is usually substituted in place of the old one, as the repairs cannot conveniently be carried out on the spot. This means finally considerable expense, as the meters often reach the repair-shop in a somewhat damaged condition. After a period of about five years, the meters are generally in such a state that they are fit for the scrap-heap. In England, the mercury meter is very popular, but the mercury requires to be kept clean. Meters are therefore usually made to consist of castings with suitable handles, so that they can be moved as required. In some cases, the Thomson meters have small openings, through which it is possible to get at the commutator and brushes. But lower prices have been quoted latterly, and these small openings seem to have been omitted from the latest designs. Some makes of meter of this type have a



replaceable commutator, but this is unsatisfactory, as a new commutator seldom runs truly. The following notes are intended to show methods by which the depreciation of meters of this type can be much reduced.

In order to start easily, the pressure of the brushes must be very light. If a commutator consists of eight sections, and makes 100 revs. per min., there will be 48,000 breaks at each brush in an hour. The small sparks that result do damage to the commutator and brushes, as shown above, magnified about 10 times. The particular meter from which the illustration was prepared had been in use about 6½ months, running 10 hours a day at three-quarters of full load. Every spark takes away a small portion of the surface of the brush f_1. These particles either fuse on the surface of the commutator or collect as small excrescences on the forward edges of the various sections. These excrescences are generally extremely hard, and are always much harder than the substance of the commutator sections and collectors, causing therefore a much increased wear. At the brush f_2 exactly the opposite process takes place, and small particles attach themselves to its surface. This has the effect of wearing away the back edges of the sections, as at *a*, which appear under the microscope at these places as rough surfaces, covered with black spots. The excrescences on the brush have, on the other hand, a spongy appearance, but in spite of this, they are none the less very hard. From this it would seem that particles are transferred from the brush f_1 to brush f_2, and a considerable number of loose metallic particles are to be found both on the brushes and on the sections of the commutator, which seems to show that the transference of the particles might be caused by friction, and not by the action of the small sparks. But, as opposed to this view, we have the fact that the excrescence always appears on the negative brush, and the pressure of the brushes, which amounts to little more than half a gramme, seems quite insufficient to cause any loss due to friction. If the commutator and brushes are rinsed with distilled water (not too great in amount), a cloudiness is formed in the water, which persists even if the water is allowed to stand for several days. With the ultra-microscope it is possible to see fine metallic particles suspended in the water, which seem to be in a state of continual motion, and reflect more or less light according to their position. Obviously this is a colloidal solution, which can be prepared, as is well known, by electrical methods. It is possible that a similar electrolytic action takes place between the brushes and the commutator sections, and the following experiment is of interest in this connection. Take a meter which shows signs of deposit on the negative brush; reverse the shunt connections, and also the connections of the series coils. The meter will continue to revolve in the same direction as before, but the polarity of the brushes is changed. It will then be found after some time that there is a complete reversal of all the processes, and the deposit will gradually transfer itself to the other brush, which was originally positive and has now become negative.

If a Thomson-Houston meter is put for some time on alternating current, deposits gradually take place both on commutator and brushes, and there is also a slight pitting. When rinsed with distilled water, there are as before signs of a colloidal solution.

As the deposit increases, so does the wear on the commutator; the brush collectors have an irregular hopping motion, and this results in increased sparking. In this state, a meter is not exactly worthless, but it registers too slowly, and errors of 15 or 20 per cent. at one-tenth full load often occur, an obvious loss to the central station. The question is what means can be taken to prevent this state of things. In the first place, the natural period of vibration of the spring-collectors should be very short. Otherwise accidental oscillations from one source or another may bring about a state of resonance, which would be accompanied by very serious sparking. It is unlikely that the period of these accidental oscillations would be very short; they would be much more likely to be long. Further, the pressure of the brushes on the commutator must be constant; the pressure should be produced by a steel spring, which takes no part in conveying the current. The pressure between two sections of the commutator ought in no case to exceed 2 volts; otherwise there is a risk of a short-circuit between the segments. The self-induction of the armature coils should be kept as low as possible. Sometimes a meter will work for a long time without sparking, whereas another similar one of the same make soon becomes useless under the same conditions. This is due to the adjusting of the spring-brushes, which is done differently by different persons. In the hope of arranging for an easy start on light load, the brushes are sometimes made to press too lightly on the commutator. In order to be independent of these chances, it has been proposed to have arrangements by which the pressure of the brushes can be directly measured; but the small amount of the pressure makes observations of this nature very uncertain, and the method has been unsuccessful. The best method is to adjust the springs carefully by hand, and it is well to leave this in the hands of one individual. With constant practice, very great skill can be obtained, and the adjustments can be very quickly made. After the springs have been adjusted, it is well to leave them one or two days in the test-room, and at the end of this time to examine them during running in complete darkness. In this way, any that show a pronounced sparking tendency can be easily detected.

Still even so, meters of the Thomson-Houston type require frequent cleaning and repairs, and it is well to see what can be done further. Some makers issue instructions to the effect that it is advisable to shift the relative positions of brushes and commutators after a certain length of time, in order to

* "Abstract of an article in the "Elektrotechnische Zeitschrift."

Digitized by Google

obtain better rubbing surfaces; but if there is a deposit already formed on the negative brush, it will be necessary to interchange the brushes if any good effect is to be produced. If the construction admits of it, it is well from time to time to change both the shunt and the series connections, thus leaving the direction of rotation the same as before; this will considerably reduce the wear and tear. An arrangement was once used by which the collectors were gradually displaced with regard to the commutator by a clockwork motion. But this was not found to prevent the deposits on the negative collector, and meters provided with this device gave at low loads readings equally as defective as those without, and sparked just as badly. A meter with defective spring contacts and rough commutator will often read quite correctly at full load, and nearly so at half load; it is only at one-fifth of full load that serious defects are noticeable. With a certain type of meter, it has been found possible to have movable brush collectors, which can be displaced more or less by the action of an electromagnet, which carries a current proportional to the whole of the current passing through the meter. Oddly enough, this simple plan has never been applied to the Thomson type, though any slight increase in cost would be more than counterbalanced by its obvious advantages. An arrangement somewhat as follows might work. Let us suppose the spring collectors to be arranged on a small lever, pivoted at its centre, and carrying a small iron armature, that could be exposed to the action of the field set up by the series coils. The design would cause the collectors to take up a different position with regard to the commutator at full load from what they would have at light load. But this in itself would be of little advantage if deposits were allowed to collect on the negative brush, as at light loads the same errors would arise as before. This could easily be rectified by arranging that, as a result of the motion produced by the action of the series field on the suspended armature, the brushes should be, as it were, lengthened and shortened. The deposits, which are mostly thrown down at times of full load, would be formed on the brushes at such points as were more or less in contact with the commutator at such times; whereas at light loads, a different position of the brush would be brought into contact with the commutator, which would be smooth and free from deposits. Under these conditions, the readings at light loads ought to remain as accurate as when the meter was new, as the low readings at light loads are almost entirely due to the irregular friction of the uneven surfaces, which is much more noticeable when the forces tending to rotate the commutator are small.

CONGRESS OF MINING AND METALLURGY.

[FROM OUR CORRESPONDENT.]

During last week there was held at Dusseldorf, in Germany, the fifth International Congress of Mining, Metallurgy, Applied Mechanics and Practical Geology. The first assembly of the kind took place in St. Etienne, in France, in 1878, followed later by meetings at Paris in 1889 and 1900, and lastly at Liege in 1905, when exhibitions were being held at these places.

Attending the present convention there are about 1,400 participants, including about 68 Englishmen and 4 Scotchmen. Representatives from Canada, India and Australia are present, whilst members from all over Europe, Mexico and South America are also in evidence.

The conventions are now expected to be held every five years, and no congress having yet been held in England it has been decided to hold the sixth meeting of such interested associations in London in 1915, and a committee has invited the entire assembly to partake of our hospitality at that time.

The progress of electricity as an adjunct to colliery and iron and steel works equipment is emphasised in the several Papers read at the meetings, more especially with reference to metallurgy and the application of power to machine driving.

The work of the Congress was divided into the following sections: (1) Mining Section, (2) Metallurgical Section, (3) Applied Mechanics, and (4) Practical Geology. Visits were also paid to several industrial works and places of interest in the neighbourhood, whilst the evenings were spent in partaking of the hospitality of our hosts.

The only Paper presented from England was entitled "British Coal Dust Experiments," the author being Mr. W. E. Garforth. Sections I. and III. contained most matters of special interest to electrical engineers, and the proceedings of these Sections we will summarise below:—

SECTION I.

THE PRESENT POSITION OF THE MINING INDUSTRY IN FRENCH LORRAINE. By P. Nicol (Nancy).

The author, in this Paper, tells of the difficulty experienced during the initial working due to the influx of water and the methods employed successfully to overcome the difficulties experienced. He mentions that both steam and electric winding engines are used in the Briery mines, the more recently installed electric plants being preferred. Electric power plants, conceived on a large scale and mostly equipped with turbines, furnish the requisite electrical energy for the various branches of the mining operations, such as winding, operating the pumping plant for coping with existing or anticipated water, underground haulages, where these are not operated by benzine locomotives, and also for drilling purposes.

THE DEVELOPMENT OF MACHINE COAL CUTTING AND PRACTICAL UNDERCUTTING IN COAL MINING. By F. Schember (Vienna).

Reference is first made to the continued use of undercutting and picking by hand with special picks of the poll, double ended and blade types. Thereafter the author traces the original construction of coal cutting machines, which consisted of picks driven into the coal by means of mechanical gearing, as used in England, America and Germany. Subsequently the rotary and chain types of machines were introduced, which the author classifies as English, American and Continental, according to the land of their origin.

Amongst the English machines, we are familiar with the wheel machine, chain heading machine and bar machine, the bar being replaced by the pusher machine in America for percussion, undercutting and nicking, whilst on the Continent the favourite machines are the sector or Eisenbeis undercutting and nicking machine and the lever machine with lever coupling control.

The machine recommended for long wall working practice is the bar machine, manufactured by Messrs. Mavor & Coulson, of Glasgow; and for all purposes where undercutting is at all possible the author prefers the use of the Eisenbeis undercutting and nicking machine.

DEVELOPMENT OF MINING INDUSTRY IN THE MINETTE DISTRICT. By Dr. W. Kohlmann (Diedenhofen).

After describing the mining work in Germany, together with the scarcity of labour, due to the difficulty attending the settlement of workmen on the top of the Briery plateau, reference is made to the application and use of mechanical and electrical energy for auxiliary purposes, such as the drilling of shot holes and the operation of underground haulages.

Electric rotary drills of German manufacture were previously much used at these mines, but favourable results have of late been obtained in several places with the pneumatic hammer drill, though the necessity of providing compressed air plant for these drills is proving a drawback, since, unlike the case of coal mines, compressed air is not required for other purposes in Minette mining. Under such circumstances the consideration of the employment of pulsator percussion drills driven by a portable electric motor at the face, as now used in Scotland and the Midlands, might prove advantageous and economical both as regards reducing capital cost and upkeep charges.

In support of this suggestion the author states his opinion that the drill of the future is the electrically-operated hammer drill, the majority of the Minette mines having at their disposal a cheap supply of electrical power from the adjacent smelting works, and there being no difficulty to prevent the laying of electric cables in the mines. The haulage roads are wide and usually straight, so that underground haulages are throughout driven by electric locomotives and stationary motors operating endless haulages.

IMPROVEMENTS IN PUMPING PLANT. By Herr Schultz (Essen).

Distinction is drawn by the author between new sets of plunger pumps and high-pressure centrifugal pumps as driven by electric motors. An electrically-worked plunger pumping plant of German design to raise 138 gallons of water per minute against a total head of 1,443 ft., and consisting of three single action plunger pumps, is described, and particular emphasis is made to the small space—only 6 ft. 6 in. by 10 ft. 6 in. foundations—necessary for pump room accommodation.

The manner in which the efficiency of individual centrifugal pumps has increased of late is a noteworthy feature typical of engineering progress, and as an example of the economical working of high-pressure centrifugal pumps a detailed description is given in the Paper of a recently installed Sultzer pump at the Emscher-Lippe Colliery, to raise in a single stage 1,320 gallons of water against a total head equivalent to 73·4 atmospheres.

SECTION III.

The Cheapening of Transport by Wire Rope and Electric Suspended Railways.

By Oberingenieur G. von Hanffstengel (Leipsig).

The wire rope railway presents very great economical advantages over the track railways, and the electric suspended railways, by reason of the convenience with which electric energy can be led where required, and possesses even a greater future for extended use. The combination of the wire rope railway with the electric suspended railway on the Bleichert system, as described by Herr Hanffstengel, offers the advantage that, without any surrender of adaptability the surmounting of elevations of any height is possible, thus making the system particularly suited for blast furnace charging.

The Influence of Electricity on the Development and Efficiency of Lifting Appliances in Mining and Steel Works.

By Fritz Heym Wetter (Ruhr).

Reference is made to the fact that the production of mines and metallurgical works depends on the lifting and conveying appliances in use. By reason of the characteristic of the electrical drive it is possible to operate the different motions with precision and rapidity as desired. The working expenses can be reduced by the centralisation of the generating plant, thereby making feasible the application of electricity where it was previously not sufficiently economical to do so. The author dwells on the advisability of installing electric winders, circular waggon tips, waggon tipping devices and loading bridges as means for increasing the output of material from the mines and the dispensation of manual labour by providing suitable gripping and tipping devices worked either by a driver or automatically. Where it would not pay to adopt large loading bridges, because of the amount of material to be handled, telpher lines, &c., with single travelling pulleys, are recommended. No workmen are necessary on the charging platform of blast furnaces if inclined electrically-driven hoists are installed. These transport the materials to the mouth of the furnace, and this practice is now universally adopted in Germany. Several special designs of cranes are described as suitable for different duties, and especial mention is made of the extended use of electric lifting magnets for entirely supplanting sling chains and lifting tackle, and it is emphasised that by employing a lifting magnet in handling scrap and similar materials the manual labour is almost entirely dispensed with and a large saving in wages consequently effected.

Underground Haulage. By Fr. Tillmann (Saarbruchan).

Mechanical haulage is now recognised as justifying the increased initial cost of installation. The most economically operated haulages are those fitted with electric motors supplied with either direct or alternating current. Where it is impossible to have an overhead line in the roadway or where, for any other reason, rope haulages are out of the question, electric accumulator locomotives may be employed to advantage.

Utilisation of Exhaust Steam and Mixed Pressure Turbines.

By Prof. Rateau (Paris).

In this Paper Prof. Rateau refers to the construction and use of his exhaust and mixed pressure turbines. In order to make it feasible to run mixed pressure turbines in parallel with other types it is necessary to keep the speed variations within certain limits. Prof. Rateau solves the problem by causing the speed governor to act upon the high-pressure and low-pressure inlet valves. The low-pressure valve is normally held open by a spring, whilst the high-pressure valve is kept closed at the same time. The low-pressure valve is subjected to the pressure variations of the accumulator. As soon as the available pressure falls below a certain amount the low-pressure valve closes and the high-pressure valve opens, thus enabling the high-pressure steam to replace low-pressure steam without variation of speed. Descriptions are given by the author of three plants where continuously running reciprocating steam engines are supplied with high-pressure steam and turbines make use of the low-pressure steam.

Heat Storage Tanks for the Utilisation of Exhaust Steam.

By E. Stach (Bochum).

It is proposed to extend the principle of utilising waste steam for the working of low-pressure reciprocating engines in the same manner as for exhaust steam turbines. The storage accumulator is an important part of such equipments. Mention is made of heat storage tanks, in which water is employed as the thermal substance, and steam-storage tanks for the reception and delivery of varying quantities of steam.

Electricity in Mining. By W. Phillipi (Berlin).

In the introduction to this Paper particulars are given regarding the extension of the application of electrical machinery in Germany, with special reference to the most economical generation of electrical energy. When dealing with the different applications of electricity to underground installations the advantages of electric boring machines, as compared with compressed air machines, are gone into in detail.

The advantages and disadvantages of ram pumps and high-pressure pumps are discussed in the Paper, and attention is drawn to the particular advantages of operating sinking pumps electrically. Chief attention is given to the explanation of a method of regulating the quantity of air circulated in the workings by centrifugal fans. Speed regulation is effected by transformers, the energy wasted in a rotor resistance being thereby utilised. Particulars are also given regarding the capital cost and annual charges of main shaft winding machines, the most important details in connection with safety working being mentioned, and particulars given demonstrating the reliability hitherto attained.

Only installations embodying the Ward-Leonard system of control, and particularly the electric winders of the Ilgner type are recommended, the reasons for their economical superiority being explained. The author refers to the suggested placing of winding engines in the hoisting framework.

Electricity in Metallurgical Work. By K. Maleyka (Berlin).

Owing to the special requirements of electrical machines in metallurgical practice it has been found necessary to design special machines for such use. The electric driving of auxiliary machines, trains of rolls and blowers is investigated, each case being treated by itself, in order to determine the motor most suitable for the particular duty. Electric furnaces, both of the induction and the electric arc type, have in recent years been installed in considerable numbers for the manufacture of high-grade steel.

The uniformly arranged central generating power station is advocated in order to reduce the costs of production of electrical energy to a low figure. Either continuous or alternating current can be successfully adopted for metallurgical work, and special arrangements for load compensation are generally necessary, either by means of flywheel buffer engines or accumulator batteries. The arrangement of switchgear, cable network and sub-stations are referred to, and data is given of the energy required for separate duties in blast furnaces, steel and rolling mill works.

Recent Experience with Large Gas Engine Installations.

By Prof. Langer (Aix-la-Chappelle).

Due to excessive continuous loads the first large gas engines had to contend with many difficulties. This condition has since been improved by the reduction of the mean effective piston pressure. It is important that the mixture should contain rather an excess of air, and that the constituents should be automatically regulated instead of adjusted by hand. In the case of engines without charging pumps this is rendered possible by a large pressure reduction in the mixing valve, so that as soon as the speed decreases, the excess of air in the mixture decreases, when the gas is under pressure. With two-cycle engines having charging pumps the composition of the mixture is affected by fluctuations in the gas pressure and alterations of the speed to a small extent. Breakage of cylinders is not caused by the explosion pressure, but by the reciprocal straining of the cylinder walls, or by the strains set up in the material of the combustion chamber due to difference of temperature. Careful design and casting of parts are the means to adopt for the avoidance of the former, whilst the latter will only be successfully overcome by the use of a casting material of sufficient strength with a smaller expansion under heat than cast iron, without possessing the disadvantages of cast steel.

The "Managing" of Power Engines, and in Particular of Winding and Rolling Mill Engines and Dynamos.

By Dr. H. Hoffman (Berlin).

This title has been chosen as explanatory of the control system for winding engines obtained by a special kind of brake. When ordinary braking is adopted the braking lever moves away from its central position and returns again, also it has to be moved in a great variety of ways, according as the load is great or small.

The principle of the "managing" system is that the managing and the managed movements are allowed to work together, so that when they do not synchronise a special movement is set up which influences the supply of power to the managed engine. By means of the application of the managing appliance, the steam winding engine and the three-phase current winding engine, whether fitted with induction motors or with double commutator motors, become just as reliable in working as the continuous-current winding engines with Ward-Leonard switchgear. At present the speed of the engine is kept constant on varying load either by hand or by a tension spring, which is not satisfactory when the load fluctuates very considerably. With the system described automatic governing is obtained by the installation of an auxiliary engine whereby movement is assisted or retarded as required.

The Rates for Subscription to "THE ELECTRICIAN" are as under—

	YEAR.	HALF-YEAR.	QUARTER.	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Canada	28s. 3d.	14s. 6d.	7s. 6d.	
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.	

New volumes of "THE ELECTRICIAN" commence in April and October.

(This charge includes all Supplements.)

Vols. I. to LXIV. can now be supplied. Price on application.

"THE ELECTRICIAN" SERIES OF STANDARD ELECTRICAL BOOKS

can be obtained of all Booksellers at Home, in the Colonies, and Abroad.

THE "ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1882. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Dec. 31st in each year for the next following edition) 8s. 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s.; Europe, 2s.; U.S.A., 3s. 6d.; other countries, 2s. 6d. *Digest of Contents sent free on application.*

THE "G.T." GEOGRAPHICAL DIRECTORY OF THE U.K. (Electrical Section). Subscription 5s., post free.

"THE ELECTRICIAN" PRIMERS (81 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three separate Vols. now ready.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS. By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [abroad 13s.

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fiftieth issue of the Supplement was published (Gratis) with the last number of "THE ELECTRICIAN."

The "INDUSTRIAL SUPPLEMENT" is a comprehensive record of developments in Electrical Plant, Machinery, Apparatus, Accessories, Sundries and Materials, and of their proved suitability for various Industrial purposes.

The "INDUSTRIAL SUPPLEMENT" is holed for filing or hanging, and filing covers can be supplied for holding 6 or 12 issues.

SPECIAL NOTICE.

NOW READY.—Vol. LXIV. of "THE ELECTRICIAN" (1,086 pages.) bound in strong cloth. Price 17s. 6d.; post free, 18s. 6d. Now ready, Cases for Binding. Price 2s.; post free, 2s. 3d.

A complete set of "THE ELECTRICIAN" can be supplied. A number of odd volumes and some odd old back numbers, to help in making up complete sets, are also available.

REPORT OF THE ELECTRICAL INSPECTOR OF FACTORIES.

There is always some difficulty in introducing new rules and regulations where an established industry is concerned, and we do not doubt that Mr. G. SCOTT RAM, H.M. Electrical Inspector of Factories, has found his hands somewhat full in regard to the new Electricity Regulations for Factories and Workshops adopted by the Secretary of State at the end of 1908, and which came into force generally on July 1st of last year. It is not often that such rules are entirely free from ambiguity, and, therefore, it is not surprising that Mr. RAM—as our readers will remember—issued some little time ago a memorandum on the interpretation of the Regulations. Mr. RAM's annual report, which was issued last week and is given in abstract elsewhere, contains some further information on the same subject.

Although there seems to be a general inclination on the part of electrical engineers, apart from those immediately concerned, to assist matters by seeing that there is compliance with the Regulations, there is considerable difference of opinion as to what is sufficient and adequate. In the case of occupiers employing responsible electrical engineers there is not so much difficulty, but there are many cases in which such a course is not deemed necessary. Where a supply is taken from public mains there is a good opportunity for the supply authority to come to the assis-

Digitized by Google

tance of the layman, and in many cases this course is being followed. For example, one local authority is issuing certificates that, to the best of their knowledge, the installations supplied from their mains are in accordance with the requirements of the Regulations. This, no doubt, is a useful course to follow, and where the electricity undertakers also carry out the wiring it is only natural that they should see that the installation is in proper order. Such certificates do not absolve the occupier from his legal responsibilities, but they are at least useful as affording some assurance that the installations comply with the Regulations.

According to the Regulations there are certain exemptions when the pressure of the system does not exceed that which is known as "low-pressure direct," or 125 volts alternating. The question has arisen whether, when a supply is taken from a three-wire continuous-current system in which the pressure between the outer conductors may exceed low pressure, such exemptions apply. In the present report Mr. RAM takes the view that such circuits should be considered in the same way as ordinary two-wire circuits in which one side is earthed. If the neutral conductor of the three-wire system is earthed then the exemptions apply, but if the neutral is not earthed the installation would not so benefit.

Mr. RAM also calls attention to the fallacy of supposing that a circuit taken from an auto-transformer and giving a low pressure, such as 50 volts, is necessarily free from danger. He points out that if the transformer is supplied at 250 volts the secondary circuit may be just as dangerous as the primary circuit if certain precautions are not adopted. If, however, the primary circuit has one conductor permanently connected to earth, it is possible to arrange the secondary 50-volt circuit so that the maximum pressure above earth does not exceed 50 volts. For this to be the case, however, it is essential that the 50-volt circuit shall have one of its conductors at earth potential. In other words, the tapping must be taken off the earthed end of the transformer, and it is essential that matters should be so arranged that the earthing is carried right through. For example, it is necessary that there should be no break whatever in the earthed conductor between the auto-transformer and the main transformer. There must be no fuse or switch in this conductor, as the blowing of the fuse or the opening of the switch would cause the whole of the low-pressure circuit to assume the full supply pressure above earth.

Part of the report refers to the design of apparatus with a view to safety. We are glad to see such points taken up year by year, as by so doing Mr. RAM can render great service to the industry by pointing out to manufacturers the weak points in existing fittings as usually constructed. In this way good results have followed his criticisms on hand lamps, and we do not doubt that more good will result from his further criticisms.

We are also glad to see that the Chief Inspector of Factories is giving serious attention to the illumination of factories. As a beginning, one of the Inspectors has been directed to inquire into the present lighting of certain classes of work-rooms, starting with underground bakehouses in London. There is a very great deal to be done in this field, for we do not really know what constitutes good illumination. Possibly the Illuminating Engineering Society might assist in some way if assistance is desired, though what is first necessary is to obtain a large quantity of data and then to determine really what these data show. When we know a great deal more about the subject it will then be possible to draw up some regulations, but knowledge is the first essential.

REVIEWS.

(Copies of the undermentioned works can be had from THE ELECTRICIAN Office, post free, on receipt of published price, adding 3d. for books published under 2s. Add 10 per cent. for abroad or for foreign books.)

Practical Curve Tracing. By R. HOWARD DUNCAN. (London: Longmans, Green & Co.) Pp. vi. + 137. 5s. net.

The scope of this book is such that the subject matter is introductory to the study of higher mathematics. The title chosen is not a particularly happy one, since it does not convey an accurate idea of the actual nature of the book, and, furthermore, the word *practical* is somewhat misleading. The curves considered are treated analytically and also synthetically, and lead in a natural way to the introduction of the calculus. In the earlier pages general information regarding the graphical representation of functions is given, and certain obvious facts respecting the choice of scales are stated, probably because students do not readily realise in a given case the practical degree of accuracy in plotting that is requisite for that case. Since the book is not written specially for engineering students, the example given (the load-extension curve for a steel bar under the action of a tensile load) in illustration of the extreme caution to be observed in extrapolation of a curve might have given place to a case of more interest to the general reader.

After reviewing the various factors relating to equations of the first degree, the author in the next 28 pages considers the parabolic family of curves, and concludes with an example (a bending moment diagram) of a practical case wherein his preceding results may be used. Hyperbolic, exponential and logarithmic curves are treated in the succeeding 15 pages, after which follow chapters dealing with sine curves and graphical solution of equations. In the chapter on differentiation the statement $\frac{dy}{dx} = \tan\theta$ should have had, in the heaviest type supplied by the printers, a note to the effect that the scales of "y" and of "x" must be considered in the determination of the value of $\tan\theta$. If students do not realise the necessity of noting the scales of the ordinates and abcissæ, the correctness of the tabulated results in connection with Fig. 68 will not be apparent. A little analytical work after treating of the differentiation of $y = f(x) = x^3$ would probably have been preferable to requesting the student to plot a curve for values of $n = 4{\cdot}5$ in the equation $y = x^n$, and then by drawing tangents, &c., to find $\frac{dy}{dx}$. Integration is dealt with in the concluding chapter; in illustration of its uses, four examples are worked out in detail. Logarithmic and sine tables, together with examples and answers, are appended.

In one place the author appears to tread very near to what in his preface is referred to as academic mathematics of the mental gymnastic order. Since both calculation and graphical work are in progress almost simultaneously, the subject of co-ordinate geometry, as arranged in this book, must be interesting to students; and, if the work set out be done conscientiously, much benefit must be derived from its study. The printing is well done, and the diagrams, 76 in number, are very clear as well as large in size.

Practical Testing of Electrical Machines. By L. OULTON and N. J. WILSON. (London: Whittaker & Co.) Pp. 210. 4s. 6d. net.

This small volume should prove a great boon to all engineers who have to test any class of electrical machinery, whether from the manufacturers' or the customers' point of view. In

Digitized by Google

very clear language is set forth the various tests usually carried out on all alternating-current and continuous-current machines, as well as the objects of each test, the method of procedure, and the instruments required; and, what is really a useful feature of the book, actual test results of various machines are tabulated and the various curves, showing their performance, plotted fully out. Divided into eight chapters, the first four deal with tests on Induction Motors, Alternating-current Generators, Rotary Converters, Synchronous Motors, and Single-phase Railway Motors. The last four deal with tests on Continuous-current Machines.

The usual guarantees as to the performance of machines are incidentally mentioned, the rules of the American Institute of Electrical Engineers being usually specified. On the whole the book is so excellent as to be beyond criticism; but some of the minor details might bear slight modification. We think the division of induction motors into (1) constant-speed motors, having short-circuited rotors, and (2) variable-speed motors with wound rotors, connected to slip rings, is somewhat artificial and misleading, as there are large numbers of constant-speed motors in operation which have wound rotors solely by reason of the starting torque which is necessary.

The more common English terms might have been used in place of "running" saturation, or "locked" saturation; and we fear the reader will have considerable trouble in understanding what the author means by "total current" on pp. 6 and 7, as English books usually express current per line or per phase. Under regulation tests of continuous-current motors mention should have been made of a stability test at top speed of shunt motors having a large speed range; when these machines are fitted with auxiliary commutating poles they have a marked tendency to run away when moderate overloads are thrown on them unless special precautions are taken to prevent this.

Considering the convenient size and reasonable price, this book should prove very popular. A. N. A.

Elementary Electrical Calculations. By T. O'Connor Sloane. (London: Crosby Lockwood & Son.) Pp. x. + 304.

In reviewing a book which emanates from another country there is always the danger that sufficient notice will not be taken of the ideas held in that country, and that, in consequence, things may be decried which are in reality "standard practice." But since science and engineering are international, we need not be unduly timid on this score, but may fearlessly point out certain points which we consider are in need of considerable improvement.

To begin with, the author has attempted too much. He has, in fact, endeavoured in a "quick-lunch" way to serve up the whole of electrical engineering in just over 300 pages, and at the same time to introduce disquisitions on algebra, trigonometry and the theory of units, matters which, as we have said before, should not be included in works on engineering. The result is that in trying to be concise Mr. Sloane becomes unintelligible and even misleading. By attempting to condense matters, which can only be fully explained in several pages, into a few lines, he is likely to confuse the student, and in being epigrammatic Mr. Sloane will defeat his own ends, for nobody will know what he means.

Turning to Mr. Sloane's book in more detail, we find that the first chapter contains some peculiar notes on elementary algebra, in which we are told that "algebraic addition is the adding together of quantities, taking their signs into account," and "algebraic subtraction is done by changing the sign of the number to be subtracted and then adding the two algebraically"; which is very nice but not very clear. Mr. Sloane's descriptions of electric measurements on p. 6 may be heartily recommended as an example of the way not to do it. Coming to the chapter on "Mechanics and Physics," we find mass, as usual, defined as "any quantity of matter," though, of course, no explanation of what is meant by matter has previously been given. In the same chapter acceleration is defined as the "change of velocity per second," leading us to wonder what the change of velocity per minute is called. The same looseness of wording, with its consequent confusion, is evident throughout the book, and it is useless to multiply instances. The explanations of electrical phenomena are hard to understand, chiefly owing to their brevity, and although attempts have been made to overcome this trouble by the sandwiching of numerical examples throughout the text, these latter, in general, are of so easy a nature that they explain nothing. The same accusation may be made against the examples which are collected at the end of the book. They are practically of the same standard, a very easy one, all the way through, though here again some uncertainty is introduced into the meaning by the author's exposition.

It is an open question whether there is any field for a book such as this, even supposing it to be accurate and well thought out. For a teacher can always supply explanations of electrical phenomena and numerical examples showing their application sufficient for his purpose from his own inner consciousness, and can, further, recommend a good text book to supplement his lectures. This last adjective cannot in justice be applied to Mr. Sloane's book.

RECENT PHYSICAL RESEARCH.

SHORT SPARK GAPS.

BY D. OWEN, B.A., B.SC.

The question of the laws conditioning the passage of an electric spark when the electrodes are at very small, indeed, microscopic or ultra-microscopic, distances apart is of much interest; for example, in regard to the action of the coherer

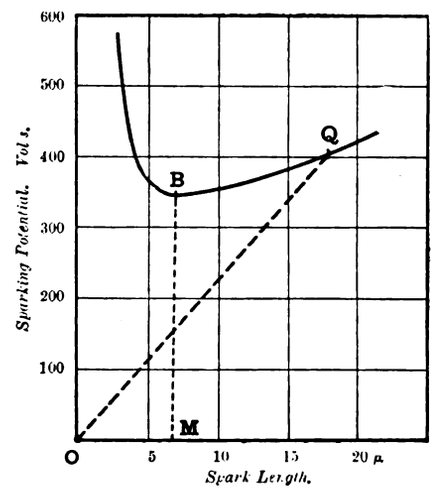

Fig. 1.—Air at Atmospheric Pressure.

detector of electric waves, or in the remarkable instrument recently devised by S. G. Brown for the relay of telephonic currents. In recent years data bearing on this subject have been steadily accumulating, which on the whole agree in pointing to certain definite conclusions.

1. It will be well before referring to this work to state the laws which hold for greater spark lengths. Where the medium in the spark-gap is a gas, the connection between sparking potential and spark length for a given pressure is of the form shown in Fig. 1, which actually represents Carr's results for air at atmospheric pressure. For sparks of appreciable length (beyond the range of Fig. 1) the curve becomes practically a straight line, and is usually represented by the equation $V = a + bd$, where a and b are constants, d the spark length. As the sparking distance is reduced, the sparking potential begins to fall off more and more slowly, until the point B of "minimum sparking potential" is reached; and beyond this, reduction in spark length necessitates increased P.D. OM is called the "critical spark length."

The minimum sparking potential is the same no matter what the pressure of the gas may be, but the critical sparking distance is inversely proportional to the pressure. For air the

Digitized by Google

value of the minimum sparking potential is 350 volts, and the critical spark length at atmospheric pressure 6·6 μ(μ = 1 micron = $\frac{1}{1000}$mm.). Results of the same form hold for other gases, the minimum potential depending on the nature of the gas, but being completely independent of the material of the electrodes.

From the form of the curve to the left of B (Fig. 1) it would seem impossible to get a spark through the gas when the width of the spark-gap is reduced much below the critical spark length. Let us consider the action from the point of view of dielectric strength, that is, the potential gradient required to produce a discharge. This quantity is represented, for any point Q on the curve, by the slope of the line OQ. As the spark length diminishes, the dielectric strength rises, the rate of rise being very rapid to the left of B.

2. However, at an electric intensity of about 10^6 volts per centimetre the law represented in Fig. 1 ceases to hold. The mechanism of the discharge appears to alter, for at that value of the field the spark once again passes. This region of short sparking distance and intense electric field appears to have been first explored by Earhart, working in the laboratories of the University of Chicago. His first Paper, on "The Sparking Distance between Plates for Small Distances," appeared in the "Philosophical Magazine" for 1901. Further Papers by him, and by Kinsley and Hobbs, working in the same laboratory, also contributions in the same field by Almy and Shaw, have since appeared. The electrodes employed were sphere and sphere, or sphere and plane, or point and plane. In Shaw's work the distance apart of the electrodes was measured

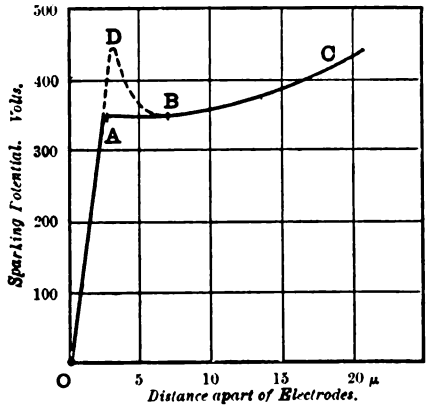

Fig. 2.—Nickel Electrodes.

with his electric micrometer, down to the extremely low limit of $\frac{1}{1000}\mu$; the other experimenters named obtained their spark lengths in terms of the wave length of sodium light, using interference fringes, by whose aid measurement to $\frac{1}{20}\mu$ is a matter of the greatest case.

Fig. 2 represents the general character of the results obtained.

From C to B the sparking potential falls with decreasing spark length down to the critical spark length, which occurs at B. From D to A the sparking potential remains constant. At A a sharp "knee" appears, and from there the curve falls in a straight line to the origin.

The dotted portion BDA represents the kind of curve that would be expected between B and A when using flat parallel electrodes. For such minute distances of separation as are here in question, however, the use of these is impracticable. As a rule at least one electrode was spherical, and in this case clearly the spark will still pass at the minimum sparking potential, not between the nearest points on each electrode, but between points at the critical sparking distance apart. Thus the horizontal portion BA is accounted for. From A to the origin the graph is a straight line, showing that the spark passes, for spark lengths below that of A, for a definite value of electric intensity, which does not depend on the width of the spark-gap.

The position of the point A might depend (1) on the nature of the gas; (2) on the pressure of the gas; and (3) on the material of the electrodes. Fig. 2 actually represents the case for air at atmospheric pressure, with nickel electrodes, the point A having as co-ordinates 2·7μ, 350 volts. Fig. 3 shows Hobbs' results for three gases. The electric field at which the knee occurs is seen to be independent of the kind of gas present. It appears to be also completely independent of the pressure of the gas (over the range of three atmospheres to 1 cm. of mercury). On the other hand, the material of the electrodes is of importance. Fig. 4 shows Hobbs' results in the case of five metals. The metals can be arranged in a series according to the slope of OA, and the results show that the heavy metals are at the head of the series. The electric intensity along OA is least for aluminium, greatest for platinum.

According to experiments by Earhart (1908), if the two electrodes are of different metals, the sparking potential gradient is determined by the metal which is the lower of the

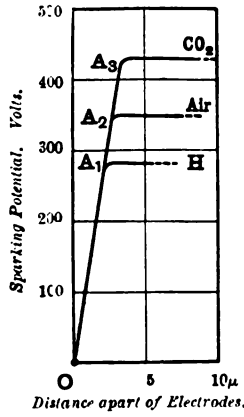

Fig. 3.—Nickel Electrodes.

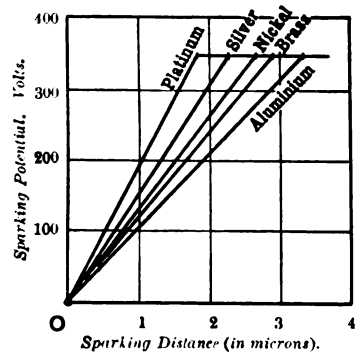

Fig. 4.—Effect of Material of Electrodes.

two in the above-mentioned series. For example, in the case of aluminium and platinum the gradient is the same as for aluminium and aluminium electrodes, and so is uninfluenced by the platinum. It is also, according to the same physicist, independent of the sign of polarity of the electrodes.

3. *Liquid Dielectrics.*—Earhart and Shaw have made experiments in which the spark passes through oil. Fig. 5 (for paraffin oil) may be taken as representative. From F to A the curve is practically a straight line. There is no horizontal portion. At A (10μ, 350 volts) a "knee" occurs. From F

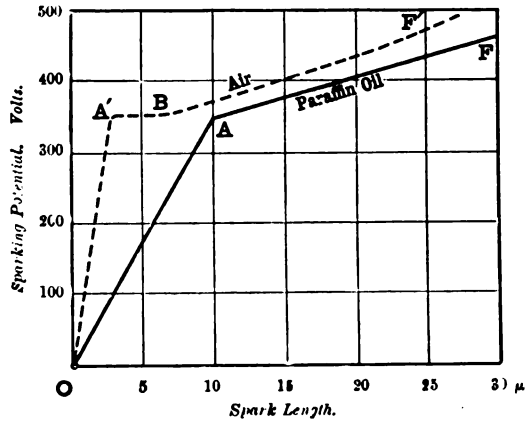

Fig. 5.—Liquid Dielectric.

to A the potential gradient at which sparking occurs has been steadily increasing. Below A the sparking potential is proportional to the spark length, that is, the sparking potential gradient is independent of distance. The dotted comparison curve is for air. The final portions, OA and OA', are similar, and suggest that the mechanism of the spark is the same in each case. It will be noted that for very short distances air has greater dielectric strength than the oil (this applies to all the oils tried), though for much larger distances the reverse is well known to be true. The cross-over point is far to the right of the limits of Fig. 5. The slope of OA depends on the oil used, though the values do not vary greatly. Earhart

Digitized by Google

gives the potential gradient for both transformer oil and paraffin oil at 15 kilovolts per millimetre, and for olive and kerosene oils at 23 kilovolts per millimetre.

4. *Electrostatic Attraction.*—For such high electric fields as those corresponding to the region OA the pull of the electrodes on one another becomes quite appreciable. The apparatus used for the above investigations had to be designed with a view to rigidity. The phenomenon of coherence of the electrodes was found to occur throughout the region from O to A, but not for distances to the right of A. This might well suggest that movement together of the electrodes had preceded the passage of current across the gap; indeed, the experiments of Almy purport to show this to have been actually the case. There seems, however, little doubt that adequate precautions were taken, and that the foregoing results should be accepted. The phenomena of coherence remain to be investigated on their own account.

In the case of a loose contact, or where variation of distance between electrodes is actually designed to take place, as, for example, in S. G. Brown's relay, it seems as if electrostatic attraction must play an important part. Consider, for example, an air-gap between flat parallel electrodes of 1 sq. mm. area, at a distance apart corresponding to the passage of a spark with a single primary battery in circuit. According to Fig. 4, the sparking distance for 1 volt is of the order $\frac{1}{3}\mu$. The electrostatic attraction is $\frac{KF^2}{8\pi}$ per square centimetre, K denoting dielectric constant, F the electric intensity. The pull on each electrode works out as 13·5 grammes weight nearly. Assuming the stiffness of the plate, regarded as a spring, on which the movable electrode is mounted, to be such as to balance this attraction for a movement equal to 2μ, we arrive at the value 6·7 kilograms as the elastic restoring force corresponding to 1 mm. movement of this spring. Unless the stiffness of the spring considerably exceeds this value the electrostatic attraction must result in actual contact of the electrodes. Except for the fact that when the spark passes the electric field rapidly falls. In oils the pull will be of the same order of magnitude.

5. *Theory of the Short Spark.*—The mechanism of the discharge to the right of OA has been very clearly established in the case of gases, in terms of the ionisation produced in the gas by the electric field. The ions present gather sufficient impetus under the action of the field to ionise molecules with which they come into collision. These freshly generated ions proceed in their turn to produce more ions. For field intensities below a certain value only the negative ions are effective. Once that limiting value is reached, and positive ions come into play, the ionisation, and so the current in the gas, increases with enormous rapidity with further increase of field, and the spark results. Townsend has worked out this collision theory in a very complete manner in a series of Papers contributed to the "Philosophical Magazine" between 1901 and 1905.

Two explanations have been advanced to account for the phenomena of the very short spark-gap, that is, the region to the left of A in the preceding figures. Shaw supposes the presence on the electrodes of a film of moisture of thickness $0{\cdot}8\mu$. Assuming this film to possess greater dielectric strength than air, the rise in dielectric strength for distances of the order 2μ and below is accounted for. Sir J. J. Thomson has suggested an explanation based on the hypothesis of the presence in metals of freely moving electrons. These electrons have rapid to-and-fro translatory motions, just like the particles of a gas. They cannot escape from the metal because of their charge. If, however, an electric field be established, with the metal as one boundary, the metal being negatively charged, then an electron that has succeeded in escaping a little way outside the metal will be aided in its outward movement by the electric field it finds outside. Fig. 6 will make this clearer. Suppose the electron, whose charge is e, to have passed to the point P, a distance r outside the metal. The method of electric images tells us that the attraction of the metal for e is the same as if a charge e of the opposite sign were placed at P′, the same distance r on the other side of the boundary AB. The pull back on e is therefore $\frac{e^2}{(2r)^2}$, that is, the same as if it were due to an electric field of strength $\frac{e}{4r^2}$, which works out at about $2{\cdot}4\times10^6$ volts per centimetre taking $e=3{\cdot}4\times10^{-10}$ E.S., $r=10^{-7}$ cm., or 10 times the dimensions of a molecule. As will be seen from the curves of Fig. 2, &c., this is of the order of magnitude of the fields actually found for the portion OA. On this hypothesis, then, the spark for these excessively short distances is due to electrons dragged out of the metal by the electric field. The value of the field at which the spark passes might be expected on this view to depend on the material of the electrodes. If negative particles ere alone concerned, the negative electrode alone should be of importance; the effect should depend on the material of the negative, but not of the positive electrode. A discharge, too, should result even in perfect vacuum. The experiments of Hobbs (*see* Fig. 4) show that the effect does vary with different metals. Both electrodes were, in his experiments, of the same metal. Earhart's experiments, referred to above, in which electrodes of different metals were employed, are, however, in opposition to the view that negative carriers alone are concerned, for the effect is independent of the sign of the electric field in the gap.

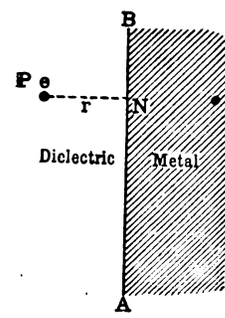

FIG. 6.

Thus far no results on the passage of the spark in the very highest vacuum have appeared.

The nature of the dielectric in the gap would be expected on this same view to be of influence, since the force of attraction on e due to the metal varies inversely as the dielectric constant outside the metal. From the numbers already quoted, it will be seen that for oils the spark occurs for fields of one-third or one-fourth the value required in air. No clear connection with dielectric constant, however, has been ascertained.

THE PROPORTIONING OF ELECTRODES FOR FURNACES.*

BY CARL HERING.

Summary.—The author describes an investigation (analytical and experimental) of the principles underlying the proper proportioning of the electrodes for electric furnaces. The author's conclusions differ very considerably from former practice.

The usual rules for proportioning electrodes for electric furnaces have been based on such factors as allowable current densities, least practicable resistance (hence shortness and large section), lowest heat conduction, the summation of losses due to the electric resistance and to the heat conduction to get the total, &c. Believing that these laws were not based on correct principles, and were therefore unsatisfactory and perhaps even misleading, and as apparently no one had made a thorough investigation of this subject based on unquestioned fundamental laws, the writer has made a careful study of the true principles underlying the proper proportioning of electrodes, based on indisputable physical laws. This analysis showed that former rules were quite incorrect and led us into entirely wrong conclusions. As the value of the annual loss of energy in such electrodes is very large, the correct proportioning is of considerable commercial importance as well as of interest to the engineer. The analytical investigation was then supplemented by an experimental one, in which the necessary physical constants and the behaviour of different electrode materials were determined. The present Paper reviews these investigations from the standpoint of the engineer who is concerned with the proper design and operation of furnaces.

Fundamental Principles.—The fundamental principle of the present analysis of the electrode problem is that the heat gradient at the hot end should be zero. This means that no heat will then traverse through the hot end, either one way or the other; hence no heat from the furnace or its products is lost through the electrode, and the

* Abstract of a Paper read before the American Institute of Electrical Engineers.

Digitized by Google

product can, therefore, not be "chilled" by the electrode, as has often been found to be the case with improperly proportioned electrodes. Such an electrode would act as a perfect heat insulator, better even than the walls of the furnace. This zero gradient can be obtained only by having the temperature of the hot end of the electrode equal to that of the furnace. In the present method, this is done by so proportioning the electrode that the current through it will raise the temperature of the hot end to this furnace temperature.

Although the writer's first recommendation of this fundamental principle was met with scepticism and even ridicule, it is now believed to be generally accepted as correct. The first impression—that this would consume much energy—is found to be incorrect; the explanation is briefly that as the heat near the hot end has no easy means of escape, a small amount of energy will soon produce a high temperature. Under simplifying assumptions (and perhaps under all conditions), this state of temperature equilibrium is found to be also the condition of minimum total loss of energy in the electrode.

Although this way of operating an electrode is quite contrary to that dictated by prior practice, which was based on the lowest practicable resistance, it turns out to be the most economical, even though it may involve an intentional increase of the resistance loss. Another advantage is that the whole interior of the furnace then becomes useful. It furthermore means that all the heat escaping at the cold end is then the I^2R heat. Or inversely, if all the heat escaping at the cold end is the total I^2R heat, and neither more nor less, then the temperature of the inner end will be that of the furnace, and there will be no loss of furnace heat and therefore no chilling.

It is evident that this condition can be reached regardless of how good or bad a heat conductor the electrode material is; even with such a very good heat conductor as copper. Hence, even without any further analysis, this shows the fallacy of the oft repeated and generally accepted statement that a good heat conducting electrode material necessarily chills the furnace, and is therefore objectionable. It will at once be seen that electrodes of good heat conducting materials must simply be made smaller in section than others.

There are also a number of other features in which the writer's conclusions differ very radically from former practice. The second one is in the determination of the total loss of energy in an electrode. Formerly the total loss was assumed to be the sum of that due to heat conduction alone, and that generated in the electrode itself by the current. The writer found that this also was a fallacy. The true total is the sum of the conduction heat and only half the I^2R heat, under the simplest condition of constant conductivities and no loss of heat to the walls. This has since been confirmed by others, and is now generally accepted. Under the more complicated conditions of varying conductivities, it is claimed by some to be only approximately true, but in any case it is much more nearly correct than the older method. It is easily seen why it should be so. The heat conducted from the furnace when there is no current, flows over the whole length of the electrode, hence the drop of temperature is proportional to the total flow; but the I^2R heat is generated throughout the whole length, hence is equivalent to the whole of it entering at the middle and flowing over only half the length, or to half of it flowing over the whole length. Hence, as far as the drop of temperature between the ends is concerned, only half of that corresponding to the I^2R heat must be added to that due to conduction alone.

A third point of difference, and one which is still adhered to tenaciously by some, concerns the current density. This was formerly the basis of electrode design, and is still considered so by some writers. The present investigation, however, has shown that the current density does not enter as a fundamental factor which determines the proportions. Even more than that: to base the proportions on current densities may even mislead one into using entirely incorrect proportions with unnecessarily large electrodes and losses of energy. It may have been found that when certain current densities were exceeded troubles arose, but in the writer's opinion the mistake made was in attributing them to the current densities instead of to the length. The writer's conclusions are that current densities need not be considered at all as a determining factor.

The fourth point of difference in the present method is in the resistance. The writer has found that the usual rule to make it as low as practicable is a mistake. It can be shown that the resistance for the most economical operation is not at all a matter of choice. It is determined by the conditions of the problem and is fixed by the temperature, current and material; it is different for different materials. Hence to try to make the resistances the same for different materials is improper designing.

This investigation applies to the electrode proper—that is, the part which passes through the walls, and in which the co-operation of the two heat flows is the governing feature. Any additional parts within the furnace or projecting outside the walls are not theoretically essential parts, even though they may be very necessary in practice, and they are evidently determined by entirely different conditions and considerations. Hence throughout the present Paper the proportions of the electrode, and particularly the length, refer to the essential part passing through the wall; the prolongations at either or both ends, if any, must be determined separately. When the metallic terminal surrounding the outside end is close against the wall and relatively short as compared with the part within the walls, it would probably be sufficient for most practical purposes to consider the electrode proper as ending at the middle of this terminal. And unless the cooling water is very close to the electrode, and the heat resistance between the electrode and cooling water is very low, the temperature at the virtual end of the essential part of the electrode will be higher, and perhaps considerably higher, than the cooling water; hence the drop of temperature in the electrode proper will be less. The author shows later that the hotter the outside terminal the smaller the loss in the electrode.

This shows the fifth point of difference from former views. Instead of trying to keep the outside terminals as cool as practicable, we ought to try so to design them as to let them get as hot as practicable, even to the extent of heating them with a lamp, when such heat is cheaper than electric heat. This will economise power, provided, of course, that the electric heat comes from the electrode proper and not from a poor terminal contact. The section of the electrode, however, becomes larger by raising the outside temperature.

A sixth point of difference from former practice brought out by this analysis is that, instead of tending to make electrodes large, we should, on the contrary, try to make them small, as they can then be just as efficient, and there may even be other advantages besides economy of material, terminals, &c., in doing so.

Another complete departure from former methods is in the abandoning of the conductivities of the materials as factors in calculating electrodes and electrode losses. The writer found that the desirable qualities of electrodes do not depend on either the electric or the thermal conductivity alone, but on certain relations between the two. The analysis shows that our former deep-rooted conviction that a high heat conductivity is a bad feature for an electrode is entirely wrong. The fact is that it may be a good or a bad quality, depending upon the electrical conductivity. In the writer's method of designing electrodes, both qualities have been abandoned entirely as a basis of proportioning, and they have been replaced by two new qualities which are true and correct measures of excellence of those materials when they are used for electrode purposes; moreover, they greatly simplify the calculations. Apparently the only objection to them is that they are not yet found in that form in tables of physical properties; they are, however, easily calculated from the conductivities if the latter are known.

These two new measures of electrode qualities are the "electrode voltage" and the "specific cross-section," and are constants for particular materials—that is, they are independent of the dimensions. The lower their values are the better is the material for electrodes.

Analytical Investigations.

The author, following the teachings of Lord Kelvin and Taite, considers it is best to solve such a problem first under the simplest possible conditions or premises, and afterward to consider the refinements. This made it possible to determine the fundamental relations or laws of electrodes. In this way it was found that most, and perhaps all, of the more important corrections due to the minor factors could be combined into two experimentally determined coefficients or constants. A method was then devised by the writer for determining these constants experimentally, and the results are given below. The premises of the present simplified analysis are: That the cross-section is uniform, that the two conductivities have the same values over the whole length, that the electrode is heat insulated except at its ends, also that the Thomson effect, the skin effect and other similar minor factors, are neglected. Under these premises the following relations are rigid and exact:—

Laws of Electrode Losses.—(*a*) The combined loss through the cold end of an electrode is equivalent to the sum of the loss by heat conduction alone (when there is no current) and half the I^2R loss. (*b*) This combined loss will be least when the loss by heat conduction alone is made equal to half the I^2R loss; the total loss will then be equal to the I^2R loss, and no heat will be conducted from the interior of the furnace. (*c*) This minimum loss is dependent only on the material, current and temperature, but not on the absolute dimensions; it merely fixes the relation of the cross-section to the length, but leaves a choice of either; hence (*d*) for economy of electrode material the length should be made as short as practical considerations permit. (*e*) For each material there is a definite minimum loss

Digitized by Google

of electrode voltage which depends only on the temperature and is independent of the dimensions or the normal current for which the furnace is designed; hence (*f*) the best possible electrode efficiency for any material may be determined from the total voltage of the furnace, and this minimum voltage due to the material and the temperature, and is independent of the dimensions. (*g*) The temperatures indicated by the heat gradient of the combined flow are equal to the sums of those of the individual flows. The proof of these laws is given in a Paper by the writer on "Laws of Electrode Losses in Electric Furnaces."*

The starting point is the fundamental principle, first announced by the writer a year ago as the proper one—namely, that no heat should leave or enter the furnace through the electrode; or in other words, that the heat generated by the electrical resistance shall raise the temperature of the hot end to that of the furnace; it is shown that under the given conditions this is also the condition of least total loss.

The author here explains that it is quite correct, and greatly simplifies the calculations to represent and measure a flow of heat in terms of watts, instead of in calories per second. Heat is energy, and a rate of flow of heat per second is power, hence it is measurable in units of power, like watts. When the heat conductivity of a material is given as 10 watts for an inch cube, it simply means that with one degree Centigrade difference of temperature between two parallel sides, and perfect heat insulation on the other four, the same amount of energy will flow through as heat, say into water at the cold end, as would enter the water from a resistance in which 10 watts were being dissipated. It is recommended that in future all thermal constants pertaining to electrodes be given in terms of watts instead of calories per second. The conversion factors are: Gramme calories per second $\times 4{\cdot}18617 =$ watts, and watts $\times 0{\cdot}238882 =$ gramme calories per second.

Formulæ.—The following formulæ are in terms of actual units, and may therefore be used directly in practice. Let S = cross-section in square inches; L = length (essential length) in inches; I = current in amperes; W = watts generated electrically in the electrode; H = heat flow in watts which would flow if there were no current; h = heat flow in watts which enters the hot end from the furnace; X = heat flow in watts leaving the cold end; T = temperature drop in degrees Centigrade between the hot and cold ends; r = electrical resistivity in ohms, inch cube units; k = thermal conductivity in watt, inch cube units; e = electrode voltage; E = total voltage between the two ends, or the watts per ampere; s = specific cross-section in square inches; S′ = section in square inches per ampere per inch of length.

In general, the flow of heat in watts at the cold end is

$$X = H + W \div 2$$

and entering at the hot end $h = H - W \div 2$, in which $H = kTS \div L$ and $W = rI^2L \div S$.

The total flow out of the cold end will be a minimum when $H = W \div 2$. Representing this minimum flow by mX, then

$$mX = 2H = W = I\sqrt{2krT} = Ie\sqrt{T}.$$

This it will be seen does not contain either S or L, which means that this is the same for all dimensions; it includes the condition, however, that the ratio of the section to the length is $S \div L = I\sqrt{r \div 2kT}$, which means that either the length or the section may be made anything one desires, provided only that the ratio is equal to the above. As the length is usually fixed by other conditions, this formula is best written $S = IL\sqrt{r \div 2kT}$.

The electrode voltage is $e = \sqrt{2kr}$, and the total voltage is $E = \sqrt{2krT} = e\sqrt{T}$, both of which are seen to be independent of the dimensions or the current, the electrode voltage being even independent of everything except the properties of the material, and hence itself a physical constant.

The total voltage E being known, a convenient way is at hand of finding out whether the hot-end temperature of the electrode is that of the furnace or not, as this voltage might be measured without much difficulty during the operation of the furnace; if the measured voltage is found to be less, the electrode is chilling the furnace, if greater the electrode is getting hotter within the wall than it is in the furnace.

The electrode voltage is that physical constant which is a true measure of the loss of power in an electrode. When multiplied by the square root of the temperature drop and by the current, as shown above, it gives the minimum loss in watts which can possibly be obtained with that material for that current and temperature. Hence if its value is known it is not necessary to know the two conductivities in order to calculate this loss of power.

The quantity E is measured directly in the experimental determinations; hence it is known for each temperature and material. Substituting its value in the equation for minimum flow gives $mX = IE$. That is, the minimum loss in watts may be determined directly by multiplying this value of E by the current; hence the voltage E may be called the "watts per ampere." This shows the simplified method suggested by the writer for calculating these minimum losses. It consists in tabulating for each material the values of E for different temperatures, as obtained directly by experiment; then for any given case, in which of course the current and temperature are given, one needs merely to multiply the corresponding value of E by this current to get the result.

Returning to the formula for S, if I, L and T are made unity, that is, for 1 ampere, 1 in. and 1 degree Centigrade, the resulting cross-section (now represented by s) becomes $s = \sqrt{r/2k}$. This the writer proposes to call the "specific section," because it is a physical property of the material.

Now let S′ be another quantity, so that $S' = s \div \sqrt{T} = \sqrt{r \div 2kT}$. It will then be seen that in the same way and for the same purpose as was described above for E as compared with e, it is possible to determine by direct measurement the values of this quantity S′ for various temperatures and for each material. When these values are tabulated it again becomes an extremely simple matter to calculate the proper cross-section, because $S = ILS'$. This quantity S′ is therefore here termed the "section per ampere per inch of length." A set of values of both S′ and E is given in a table in the Paper. When S′ is not known, then $S = ILs\sqrt{T}$. It will be seen that again the two conductivities drop out and need not be known. In the absence of these tables the values of e and s should be used. If they, too, are unknown, the mean conductivities must be resorted to. If in turn these electrode means are not known, and the conductivities at the specified temperature are known, the mean values must first be determined from them. The writer calls attention to the fact, on which particular stress was laid in his first published description of his method, and which fact has been entirely ignored by the critics, that the curve of the combined losses is quite flat at its minimum point. This means that a considerable error can be made in the cross-section without affecting the power loss appreciably.

Various other relations exist between these old and new quantities which at times are of interest and use. They are easily deduced, and are therefore merely summarised here—viz., $e = I \div W\sqrt{T}$, $e = r \div s$, $s = e \div 2k$.

All the above is based on the premise that the temperature variations of the physical constants may be neglected; this so greatly simplifies the formulæ and relations that the numerous useful and interesting results given above are obtained. In the present method the values of the conductivities and other deduced factors obtained are the mean values peculiar to electrode conditions. What they really represent are the values of another, or "equivalent electrode," the conductivities and other properties of which are the same as these mean values, and are constant from end to end—that is, they are independent of the different temperatures along the electrode. Such an equivalent electrode will, as a whole, operate in exactly the same way, and hence, as far as the flows of heat at the two ends are concerned, it is theoretically identical. It differs, however, in the shape of that part of the temperature gradient which is intermediate between these two end points.

(*To be concluded.*)

CORRESPONDENCE.

FISCAL POLICY AND THE ELECTRICAL INDUSTRY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In Mr. Hookham's letter of the 14th one sees exposed, in all its nakedness, the basic error of the free importer's mind. In his last paragraph he declares that his own interests, and those of Mr. Arthur Chamberlain, are opposed to those of his country. Coming from one whose exceptional talent and life-long work has been a great benefit to his country, and the admiration of all who know him, such a statement passes my understanding. Perhaps it is because I am an "average manufacturer," and not a "life-long student of economics." Yet I believe myself able to understand the men who have done more than argue—laid down their lives for their country, thankful for the privilege, and proudly conscious of the fact that it was "in their own interests."—I am; &c.,

EFFICIENCY OF SHORT SPARK METHOD OF GENERATING ELECTRICAL OSCILLATIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Messrs. Eccles & Makower accuse me of begging the question by equating the efficiencies before and after quadrupling the power which doubled the aerial current (and also the primary current), as found by experiment.

Double the aerial current involves four times the aerial energy expenditure, on the authority of Hertz, who for his part applied Poynting's theorem to calculate radiation. If four times the power supplied produced four times the aerial energy the efficiency was unchanged; wherefore it is experiment and not my fancy which disposes of the argument advanced by my contradictors.—I am, &c.,

Lyons, June 20. R. C. GALLETTI.

We have submitted Mr. Galletti's letter to Messrs. Eccles & Makower, from whom we have received the following reply:—

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Accepting as an experimental truth your correspondent's statement that quadrupling the power supplied to the spark-gap doubles the oscillatory currents in the primary and secondary circuits, what follows is that if the efficiency of transference before quadrupling is the same as that after, then the resistance of the spark-gap is the same before and after; but if, on the other hand, the efficiency is not unaltered the resistance is not unaltered. This was what we indicated in our last letter.

It appears that Mr. Galletti's attack on our protracted series of direct measurements of efficiency is based on a rough indirect method of estimation carried out with apparatus whose details have not been divulged. We shall be better able to discuss Mr. Galletti's suggestions when he has made and published a substantial series of measurements and a full description of the apparatus used.—We are, &c.,

W. H. ECCLES.
A. J. MAKOWER.

South Western Polytechnic Institute, London, June 28.

COST OF ELECTRIC POWER AT NIGHT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The remarks in the leading article in your last issue with reference to the phenomenal results tentatively put forward by Mr. Shawfield are very interesting. I have for the past three or four years been endeavouring to bring it home to electrical engineers that there are certain conditions in a night (and sometimes in a day) load when quite a considerable number of extra units could be generated at a ridiculously low price for coal charges, but I have never in my wildest dreams got quite so far as the results quoted by you. Knowing, however, the careful way in which Mr. Shawfield usually keeps his records, it seems highly probable that the coal bill due to the additional units was an exceedingly small one, and is a further justification of the use of accumulators in stations where such conditions obtain. Not that I have any doubt but that their use can be justified in the great majority of cases, but I am persuaded there will be found many cases where not only in the dead of night, but at intervals during the daytime, the charging of accumulators can be carried on at a ridiculously low cost.

The whole point of my 1908 I.M.E.A. Paper was to bring home that if the cost of the energy going into the cells was of the order of 0·1d. or 0·15d. per unit, and if the discharge was available for peak purposes when the energy was worth four to five times that amount, the inefficiency of the accumulator (which has been made so much of) becomes of correspondingly little importance. It is pleasing to know that many engineers are beginning to recognise this, and that there are occasions when the cost of the energy entering the cells can reach such low figures as those suggested.—I am, &c.,

Birmingham, June 28. A. M. TAYLOR.

ELECTRICAL PROPULSION OF SHIPS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read with great interest the articles in your special Marine issue describing systems of electric propulsion, and more particularly what has been said regarding the adaptation of the squirrel-cage type of induction motor for propelling ships, this motor being of the utmost practical value. It appears to me that variation of speed by altering that of the turbines is not so simple or so efficient in steam consumption as where the turbine or prime mover is kept at constant speed, working within the range of its best efficiency, and at the same time the speed of the motors is varied by the frequency and voltage at their terminals. The question of efficiency of the turbine running at its most economical speed is the determining factor in favour of electric propulsion of ships, where the number of generator units can be varied as the demand for power varies, instead of having to use all these units at a low steam economy when permanently fixed on the propeller shaft, as now in use in our large turbine-propelled ships.

The cardinal and starting point for design is propeller efficiency, coupled to the most economical turbine speed—*i.e.*, the minimum of steam used, with the maximum of propelling efficiency of the boat. If a high-speed propeller could be used with advantage a still higher turbine and motor speed could be adopted, with consequent saving in weight all round.

In all transportation problems the vital economical question is the cost of fuel per ton-mile. Now which is the cheapest system to equip and maintain to obtain this object at sea, not forgetting speed?

I think, sir, that you have done the electrical and marine industries a good turn in issuing this very interesting Marine Number.—I am, &c.,

Golder's Green, June 23. A. H. BINYON.

FARADAY SOCIETY.

At the meeting of the Faraday Society held on Tuesday, June 21st, in the rooms of the Chemical Society, Burlington House, W., Dr. F. M. Perkin, treasurer, in the chair, M. PAUL GIROD sent in a Paper entitled

"Studies in the Electro-metallurgy of Ferro-Alloys and Steel," which, in the unavoidable absence of the author, was read by Mr. F. W. Harbord.

The first portion of the Paper describes the various ferro-alloys which are manufactured in Girod furnaces at the works of the Girod Company at Courtepin (3,000 H.P.) and, principally, at the new works at Ugine (20,000 H.P.), where the furnace electrodes are made.

Ferro-Vanadium.—Two varieties are made, one containing 45 to 55 per cent. vanadium and 3 to 3·5 per cent. carbon, and the other 30 to 40 per cent. vanadium with 0·5 to 1·5 per cent. carbon. This alloy is employed almost entirely in the manufacture of rapid tool steels with great cutting powers.

Ferro-Tungsten.—Three alloys are made, containing respectively 83, 78·5 and 73 per cent. tungsten and 0·6, 1·7 and 3·5 per cent. carbon, mostly used for steels to be tempered in air.

Ferro-Molybdenum.—This alloy carries 75 to 80 per cent. molybdenum and 3 to 4 per cent. carbon. The sulphur is removed from the high sulphurous ores in the electric furnace in one operation. Experience has shown that the high carbon content facilitates the fusion and the mixture of this and the vanadium alloys.

Ferro-Chromium.—The principal alloys made contain about 60 per cent. chromium and from 0·6 to 9 per cent. carbon, with 0·2 to 2·25 per cent. silicon. For the removal of oxygen from fine steels silico-manganese-aluminium and silico-calcium-aluminium alloys are made.

Ferro-Silicon.—This is the alloy most largely used, and the varieties made contain 25-30, 40-75, 75-80 and 90-95 per cent. silicon. The first of these is employed principally in converters, and the richer alloys chiefly for the removal of oxygen and for silicon-steel to be converted into transformer iron. There are 30 furnaces at Ugine, 18 utilising 300-750 H.P., and nine about 500 H.P.

Digitized by Google

Electric Steel Furnace.—The second portion of the Paper describes the Girod steel furnace with conducting hearth now in wide use for converting scrap-iron into best quality steels. A feature of the furnace is that the metal conductors have only to be slightly water-cooled, at the parts not in contact with the molten metal, and their life is almost infinite. The large furnaces have a capacity of 15 tons. The mean content of the charge used at Ugine includes 0·3 to 0·4 per cent. carbon, 0·1 to 0·3 silicon, 0·6 to 0·8 manganese, 0·07 to 0·12 sulphur and 0·07 to 0·12 phosphorus, while the best refined product contains 0·05 to 1·5 per cent. carbon, 0·15 to 0·25 silicon, 0·25 to 0·35 manganese, 0·015 sulphur and 0·015 phosphorus.

The Paper concludes with an outline of the two processes, oxidation and reduction, which constitute the refining action of the electric furnace. Tables showing the mechanical qualities of the products are appended.

The CHAIRMAN, in opening the discussion, remarked on the comparative backwardness of this country in the adoption of electric steel refining. The question of cheap power in this connection was not so vital as was sometimes supposed.

Dr. W. ROSENHAIN thought that if the claim that best tool steel could be made from scrap was true, it would revolutionise the Sheffield steel industry. He believed the Sheffield manufacturers were alive to this, and were experimenting in a careful and systematic manner.

Mr. W. R. COOPER also remarked on the fallacy of attaching undue importance to cheap power.

Mr. E. RISTORI pointed out that practically all types of electric furnaces in use absorbed about the same amount of energy per ton of steel. England had not taken the lead in this matter of electric refining, and she was not following quickly enough.

Mr. F. W. HARBORD, referring to the remarks of the previous speaker, said the value of the results obtained in an electric furnace depended on the facilities present for removing slag carrying the impurities. Recent forms of induction furnaces now made provision for this. He personally had no doubt that steel equal to the best crucible steel could be made from scrap in the electric furnace.

Mr. ERNEST F. LAW then read a Paper on

"The Failure of the Light Engineering Alloys, particularly the Aluminium Alloys."

The author draws attention to the fact that recent developments in aviation and other branches of modern engineering have created a rapidly increasing demand for suitable light alloys, and that up to the present the metallurgist has not been able to meet this demand satisfactorily. Considering the expectations which were entertained for the aluminium alloys a few years age, we are forced to the conclusion that in this respect aluminium has been somewhat of a failure.

The constitution of the alloys is then briefly dealt with, and the fact noted that aluminium does not alloy in the true sense of the word with most of the common metals, but combines with them to form brittle metallic compounds. These alloys, during the course of time, spontaneously disintegrate and fall to powder. This fact appears to have been first noticed by the late Sir Wm. Roberts-Austen, and is due to a molecular or allotropic change taking place in the solid alloy. As so many of the alloys undergo this molecular change, it is probably due to an inherent property of the aluminium, and the question is raised as to whether it is possible that aluminium itself exists in two allotropic forms, and that the change from one to the other becomes apparent when the metal is alloyed with another metal. It is shown that there is evidence in favour of this view, inasmuch as aluminium is known to undergo physical changes during cooling. The evidence is considered briefly, and it is pointed out that, judging by the experience we have gained in the case of the allotropy of iron, if aluminium also proves to be an allotropic metal, then a study of the molecular changes may lead to results of the utmost practical importance.

The CHAIRMAN said that metals other than aluminium, such as calcium, manganese and chromium, disintegrated in the way described in the Paper.

Dr. R. SELIGMAN said the lack of cohesion in aluminium below its melting-point existed in the very purest specimens. He, therefore, questioned whether the phenomena described was due to impurities.

Dr. J. A. HARKER described some experiments he had made in the cooling curve of very pure aluminium. An indication of a kink in the curve appeared at 630°C. (m.p. 657 deg.), but the results were not satisfactory.

Dr. W. ROSENHAIN thought the failure of aluminium alloys was less than the Paper would seem to suggest. He described the microscopic changes that he had observed when Al-Mg alloys disintegrated. These polymorphic changes that took place were not confined to metals; they occurred, *e.g.*, in certain silicates of calcium. He believed that allotropic changes in metals depended on the presence of other metals.

Mr. W. H. MERRETT described experiments he had made which confirmed what had been said regarding the anomalous behaviour of aluminium and its alloys. It was interesting that the addition of 5 per cent. bismuth greatly facilitated the turning and casting of aluminium.

Dr. T. M. LOWRY said it was remarkable that, unlike other metals, the addition of aluminium and silicon did not harden iron, while it increased its magnetic permeability and decreased its retentivity.

NATIONAL TELEPHONE CO.'S STAFF DINNER.

The sixteenth annual dinner of the staff of the National Telephone Co. was held at the Trocadero Restaurant, London, on Thursday evening last, and was, as usual, numerously attended, the staff and guests numbering about 300. The chair was occupied by Mr. ALBERT ANNS, who was supported immediately by Mr. Geo. Franklin, Litt.D., president of the company; Lord Harris, Sir Albert Rollit and Mr. W. A. Smith, directors; Sir Robert Hunter, C.B. (solicitor to the Post Office); Sir John Gavey, C.B., Sir Alex. Kennedy, LL.D., Major O'Meara, C.M.G., Mr. Leonard Stokes, R.I.B.A., Mr. A. H. Norway, Mr. Frank Gill (engineer in chief), Mr. S. J. Goddard (general superintendent), Mr. Edward Morton, K.C., Mr. H. H. Gaine, Col. C. B. Clay, Mr. H. Laws Webb, Mr. H. Graham Harris, Mr. G. F. Preston, Dr. R. M. Walmsley, &c., &c.

After the loyal toasts, and a feeling reference to the death of the late King Edward,

The CHAIRMAN said they would join with him in regretting that neither the Postmaster-General, nor the Assistant Postmaster-General, nor the Secretary of the Post Office were able to be present that evening. Sir Matthew Nathan had accepted their invitation, but owing to the fact that the Post Office Vote was being discussed in Parliament he was unable to be amongst them. The British Post Office was a marvellous organisation, and they were justly proud of it. The last 12 months had been, like many years before it, a period of hopes and disappointments. Last year there were rumours of an early settlement of the main points that had arisen in connection with the transfer of the National Company's undertaking to the State, but the present moment found them preparing for the great fight which was apparently inevitable. There were many gentlemen present, as their guests that evening, who would become their adversaries when the time came for the final struggle. They were great fighters, but they were fair fighters, and whoever came out on top would, he hoped, deserve that desired situation. He put the cost of fighting the final settlement as not far short of £100,000. With regard to the development of the telephone, the National Company were spending about half the amount on the development of their business that they were spending two years ago. This notwithstanding, their revenue and their profits were progressing in a most satisfactory manner, and they hoped next year to be reaping a golden harvest from the seed which had been sown in past years. He regarded the prospects from the shareholders' point of view as very bright. He did not, however, think they were quite so brilliant from the staff's point of view. Reduction in capital expenditure, of course, meant less employment, and although successful efforts had been made to provide work for the construction staff, it had still resulted in hundreds of the company's men having to seek employment elsewhere. They were sorry to lose these men, and heartily wished them the best of good luck in their new surroundings. There was still the municipal competition at Hull and Portsmouth, but he thought it would not be long before this would be extinguished. With regard to the transfer they would be handing over to the State over 500,000 clients and a revenue of between 3½ and 4 millions a year. He thought it would be agreed that the transfer of such a highly valuable undertaking and organisation was one unique in the annals of this or any other country. The dead assets—the poles, wires, switchboards, instruments and so forth—were to be scheduled and valued, but the live assets, the brains and the energy and the devotion which had created that wonderful business would not be valued; but they were priceless assets. He knew that many of the staff were worried and unhappy as to their future prospects, and he could only echo the regrets of the president and other members of the board of directors of the National Company that they were unable to give the staff those full assurances that would make them as happy and contented as they deserved to be. He still hoped and believed there would be a happy issue out of all their afflictions. He took that opportunity of congratulating the Staff Transfer Association upon the good work it had done. He understood that the outstanding burning question was the claim made by the association on behalf of the staff that service with the company should count for the purposes of pension and other matters as service for the State. He hoped their future masters would remove any doubt on this point. He asked them to drink to the toast of "Success to the National Telephone Company," coupled with the name of their esteemed president, Mr. Geo. Franklin.

The toast was drunk with great cordiality.

Mr. FRANKLIN said it had been for several years his good fortune to respond to this toast and to acknowledge, on behalf of the directors, the hospitality of the staff. At present the subject they were all chiefly concerned in was what a Scotch divine had called their "latter end." The transfer of their undertaking to the State involved questions of the highest importance and the utmost delicacy of treatment, and just as in the past the company had been able to count upon the loyalty and devotion of a united staff, he ventured to hope this co-operation would continue until the transfer was an accomplished fact. Those who had shown such loyalty to the company might be relied upon to show equal loyalty to the State, their new masters. When the Post Office took over the 18,200 servants of the National Company, they would find this a most important asset. During the past year the company had added 32,153 stations, bringing the number up to 516,888. The company had now 1,569 exchanges, an addition of 14 for the year, and the total messages transmitted over their lines had been 1,362,000,000, an increase of 39,000,000 on the year, the cost per message being 0·51d. It was to the credit of the company that within a year's expiry of its licence it had still put on 30,000 subscribers in a year and was spending money in catering for the needs of this large addition to its customers. He

Digitized by Google

could imagine companies with less public support and a less high ideal might be content with letting matters go. The board of the National Telephone Co. would cordially join hands with the Post Office in order to arrive at a satisfactory solution of the problems before them, which he hoped would result in justice being done alike to the staff and to the shareholders of the company (cheers).

Col. C. B. CLAY proposed "Our Guests," and expressed the happiness of the staff in having among them a number of their directors, a number of representatives of the Post Office, and an old colleague, Mr. Preston, engineer of the State Post Office telephone service. There were also present many representatives of the engineering and legal professions, whom they cordially welcomed. He would specially mention Sir Alex. Kennedy, Mr. Edward Morten, K.C., and Mr. Leonard Stokes, who had been chosen as president of the Royal Institution of British Architects. He coupled with the toast the names of Sir Albert Rollit and Sir Robert Hunter.

Sir ALBERT ROLLIT said he appreciated the conjunction of his name with that of Sir Robert Hunter. He appreciated also the kind remarks which had fallen from Col. Clay, and in reply might say that the directors had always tried to be on good terms with those with whom they had been associated in the great enterprise of the National Telephone Co. It was pleasant for the directors to know that this position had been recognised by the staff. They might all be proud of having belonged to the National Company, which might pass away, but that pride would still remain. They had been pioneers of speedy communication. As a guest he greatly valued the splendid hospitality which the staff extended to them, and especially on behalf of the directors he returned hearty and grateful thanks (cheers).

Sir ROBERT HUNTER joined in the regret expressed by the chairman at the absence of other representatives of the Post Office. He had been present at many of these dinners, and looked back upon them with great pleasure. Amongst his memories were those of Mr. James Staats Forbes. He had negotiated with him, had dined with him, and had heard him tender evidence before a Select Committee, and he was not sure in which capacity he most admired him. He also had agreeable memories of their late manager, Mr. Gaine, who had on numerous occasions conducted important and delicate business with him. Amongst recent recollections, he remembered that Mr. Anns, in presiding last year, expressed a presentiment that that dinner might be their last, and it would be remembered by those who were then present that the president, Mr. Franklin, premised that on the next occasion Sir H. Babington Smith (the then Secretary to the Post Office) might be in the chair. Neither prognostication had eventuated. On the contrary, the only difference between their present gathering and that of last year was that Sir Babington Smith had left them. He believed there was a reason for this, and it was that Sir Babington had come to the conclusion that he could make nothing out of Mr. Franklin, and was destined to undergo a crushing diplomatic defeat if he remained at the Post Office. He was now living on the shores of the Bosphorus in comparative poverty (laughter). Coming to the transfer, one thing seemed certain, that before long the gentlemen representing the staff of the National Telephone Co. would become, directly, servants of the State, and when that event happened he was sure they would receive a most cordial welcome at the hands of their colleagues already in that service. In fact, he regarded that fellow-service as already existing. For nearly 30 years the company had conducted a great and most important branch of the telegraph service. He thanked them for the cordiality with which the toast had been received.

Mr. A. E. RUDDOCK proposed the toast of the chairman. Mr. Anns' abilities were obvious to every member of the staff, just as his caligraphy was often—at least once a month—very welcome; but it was not so much his ability that appealed to them as his character, his personality, and the absolute assurance that every member of the staff felt in his fairness. There had never been the least suspicion of favouritism of any kind, and it was that feeling which made Mr. Anns what he was to them. When the time came for the transfer, there would be many who would miss the old company, and their old leaders, but whether Mr. Anns remained to take an active part in telephonic matters or transferred his activities to other spheres the staff would always remember him with esteem and affection (cheers).

The toast was drunk with musical honours.

The CHAIRMAN having briefly replied, a very enjoyable function terminated.

During the evening an excellent musical programme was provided.

L.C.C. TRAMWAY ACCOUNTS.

On Tuesday the Finance committee of London County Council reported on the accounts of the tramways department for the year ended March 31.

The total capital expenditure to March 31, 1910, amounted to £10,709,504, of which £1,225,942 was incurred during 1909-10. The outstanding debt was £9,017,507, the difference (£1,691,997) having been paid off, including £1,372,337 (12·8 per cent.) out of revenue. Deducting the value of surplus lands held as an asset against debt (£118,408), the net debt was £8,899,099. There is a reduction of £9,010 in the amount (£1,032,446) of debt outstanding on account of obsolete capital expenditure.

The available surplus, after meeting charges for interest, repayment of debt and other items, was £192,109, an increase of £3,783 over the original estimated surplus (£188,326). £7,273 of the surplus is due to an unusua credit in respect of income tax overcharged in previous years. The committee think that, considering the magnitude of the estimates and the difficulty of forecasting the dates when various sections of the lines will be reconstructed for electric traction, the close approximation of the actual to the estimated results is very satisfactory.

Taking the result of the electric system by itself, the surplus on working is equal to 44·11 per cent. of the gross receipts, against 42·99 per cent. in the previous year. The traffic receipts obtained from the working of the electric lines averaged 11·21d. per car-mile, and, including advertisements and other sundry receipts, the total receipts were 11·48d. a car-mile, against 11·81d. The decrease was due to the abnormally wet summer. The average fare was 1·06d., compared with 1·07d.; the expenses worked out to 6·42d. a car-mile, including 0·85d. for power. Adding 0·73d. for debt charges in respect of power, the total expenses for power were 1·58d. a car-mile, against 1·71d. in 1908-9. The decrease in cost of power, due to the development and fuller use of Greenwich generating station, was to be noted with satisfaction. In 1906-7, the first year of working the station, the total cost of power was 2·07d. a car-mile. Including debt charges for power, the total expenses worked out at 7·15d. a car-mile, compared with 7·37d. There was also a slight decrease per car-mile on the other heads of expenditure in respect of electric traction. The surplus on working was 5·06d. a car-mile, against 5·07d., 5·16d. and 5·17d. in the three preceding years. Although the receipts per car-mile were decreasing, the expenses were also decreasing, with the result that the surplus of 5d. a car-mile, on which financial estimates for some years have been based, has been maintained, but with an increasingly small margin. Only about 20 miles of horse lines remained open at the end of the year, and the estimates of 1910-11 provide for the electrification of about 14½ miles of horse lines, which will leave 5½ miles still to be dealt with.

Provision for renewals at ¾d. per car-mile run on lines worked by the Council required £110,060 out of the net surplus of £192,109. Adding to this £21,571 for shortage of previous years and £600 in respect of the Harrow-road lines, which are not worked by the Council, the total provision made in the year for renewals was £132,231, leaving £59,878 to be transferred to general reserve. The total in the renewals fund was £395,022, of which £336,266 had been invested. The general reserve fund had been increased during the year by interest on the corpus of the fund and by £59,878, the balance remaining of the surplus on the year's working after providing for renewals. After deducting expenditure of £25,265 in connection with the reconstruction of the Aldgate to Bow lines, the balance of the fund was £70,752. Out of a total of £723,386 chargeable to the tramways account in respect of street improvements, £305,090 has been brought into charge up to March 31, 1910.

Discussion.

Mr. E. WHITE, in moving the adoption of the estimates, said the committee were dealing with the question of the electrification of the horse lines, and 14 miles of such tramways were practically in hand. They still had some 9 miles of single track to deal with, but there they had to contend with difficulties. The Council were very generous in the matter of workmen's fares, and the total number of people who availed themselves of such facilities last year were 29,969,000. There had been a great increase in ½d. fares, of which there were some 236 stages. The number of passengers carried on the ½d. stages had increased from 20·12 per cent. in 1906-7 to 25 per cent. If the Council insisted upon reducing fares and extending the length of the stages the Highways committee must not be blamed if the financial results were unsatisfactory. The rate per car-mile had already fallen 11·48d., and if the amount fell by another ½d. the balance now shown would disappear. The Board of Trade had granted permission for the use of trailer cars in order to obviate the difficulty of overcrowding, and experiments would shortly be tried on the Euston-road to Hampstead Heath line.—The estimates were passed.

TECHNICAL EDUCATION CONFERENCE.

The fourth annual conference of the members of the Association of Teachers in Technical Institutions was held at Birmingham last week.

The president (Mr. J. WILSON, of the Battersea Polytechnic), in the course of his presidential address, said that their membership was steadily increasing, and with it their prestige, influence and usefulness. The future position of England as a front-rank commercial nation depended mainly upon the increased application of scientific knowledge and methods to industry and commerce, and the thorough technical training of all ranks of the industrial army. Public opinion was gradually awakening to the claims of technical education, but the progress was slow. In its utilisation of science and its attitude to higher education the English manufacturing world, despite recent advances, was some decades behind its chief competitors, the German and American manufacturers. Let them consider, for instance, the new industries which had come into existence during the last 15 or 20 years, as, for example, the manufacture of motor cars, aeroplanes, metal filament lamps, incandescent gas mantles, machine tools, high-speed steels, synthetic indigo, calcium carbide, artificial silk, and many other examples which might be selected from the engineering, electrical, chemical or metallurgical industries. All of these were either German, French, or American in their origin or commercial development; none English. It was true that certain of the above industries were now in more or less profitable operation in England, but the English manufacturer, coming later in the field, was handicapped by the fact that he had to

Digitized by Google

fight against the acquired knowledge and the business connections already obtained by the Continental manufacturer in the early years of the industry. In their work as technical educators there were two distinct problems to be considered: (1) The training of the manager, the scientific director or the "captain of industry." (2) The training of the foreman, the artisan and the craftsman. At present, owing to the lack of a sufficiently wide and far-reaching scheme of national education as a whole, the country was making but little use of what might be one of its greatest assets, the practical and mental genius of its people. The greatest weakness of our present system of technical education lay in the higher branches, especially in the matter of day technical work. Thus, whereas in Germany there were in attendance during the session 1907-8 at the 10 technical universities no fewer than 11,692 fully-qualified and 2,299 partially-qualified day students; in England during the same period there were only 4,068 more or less qualified day technical students attending the various university colleges of university rank, and the London and provincial technical schools. Compared with the German students, the English students were much younger, their preliminary training was less thorough, and their period of study shorter. The equipment and courses of study of the English institutions were undoubtedly inferior to those provided by the German technical high schools. The reason was the relatively small demand in England for the highest form of technological training. Given a greater demand, the equipment and courses of study at English technical institutions would speedily equal, if not surpass, those of any of the Continental technical institutions.

One of the problems now demanding consideration was the question of the relationship of the higher work of technical institutions to that of the technical departments of local provincial universities. At present the question was in a very unsatisfactory state, resulting at times in preventing much needed developments of their work, in the dissipation of educational energy, and the waste of money through unnecessary duplication of buildings and equipment. The two essential points in any schemes for the co-ordination of university and technical institution work were: (*a*) There must be no curtailment of already existing facilities offered to students, especially to evening students who could not afford the time or the money to make long journeys to distant centres, and (*b*) the position of teachers must be adequately safeguarded. One of the most pressing requirements of English higher technical education at present was the need for an adequate system of scholarships with maintenance allowances whereby evening students who had reached the necessary standard could be enabled to devote two or three years to further specialised study in the daytime at a fully equipped technical college. The present systems of scholarships rarely reached this class of student. A beginning had been made in this direction, notably in London and Leeds, but the system was only in its infancy. Much of the money now spent in the provision of scholarships and bursaries for the training of elementary school teachers, some of whom could not secure appointments at the close of their college career, might well be diverted for that purpose. Under present conditions only a relatively small proportion of those to whom technical education would be beneficial attended any day or evening technical courses. The technical institutions of this country reached at the present time only a very small percentage of those who yearly entered our great industries. They believed that the following reforms would materially lessen the evils indicated: (1) No child should be allowed to leave school before the age of 15, and the half-time system for children under 15 should be abolished; (2) improvements in the curricula and methods of the elementary school; (3) the institution of a system of "technical" secondary schools (including trade schools) in addition to, or in partial replacement of, the existing type of "literary" secondary school; (4) compulsory attendance at day or evening (preferably day) continuation schools, coupled with a limitation of the hours of labour of adolescents; and the affiliation of the continuation schools to the technical school.

A number of resolutions dealing with technical education were approved and passed.

The congress of the Irish Technical Instruction Association was also held last week, the meeting taking place at Sligo under the presidency of Mr. F. C. Forth, of Belfast. A number of interesting Papers relating to technical education were read and discussed.

PARLIAMENTARY INTELLIGENCE.

P.O. TELEGRAPHS AND TELEPHONES.

In the House of Commons on the 23rd inst., the POSTMASTER-GENERAL (Mr. Herbert Samuel), in dealing with the Post Office Estimates, said that the total sum for which he had to ask the sanction of the House was nearly £20,000,000. Fifteen years ago the Post Office Estimates amounted to about £10,000,000. Fortunately, the receipts had nearly doubled also, and the profits remained about the same as they were 15 or 16 years ago. The Post Office dealt with 15,000,000 letters and ½d. packets every day. They handled about 250,000 telegrams daily. During the past year the telephone business had shown considerable expansion. 123 new exchanges had been opened, the number of subscribers to the Post Office system had increased by 12 per cent., the number of conversations on the trunk lines had increased by 15 per cent., and they were looking forward at a very early date to taking over the whole of the vast enterprise of the National Telephone Co. Arrangements were now being rapidly pushed forward to take up the transfer at the end of next year. Two Departmental Committees were at work within the Post Office, one dealing with the question of telephone plant and the other dealing (among other details) with the important question arising out of the transfer of the telephone staff and the arrangements for taking a general inventory. A Bill would be required for the purpose of the transfer. It was not intended, as at present advised, to introduce it this year, but probably at the beginning of next session, and that would be the moment to consider the question of finance; but it was anticipated that the terms of the transfer would be in accordance with the agreement entered into by the late Government, and he had very small hope that those terms could be settled otherwise than by arbitration as provided for in the agreement.

Wireless Telegraphy.—The system of wireless telegraphy also showed very rapid expansion. One of the many items of enterprise which made the administration of his predecessor noteworthy was the purchase last autmun of the wireless telegraph stations round the coast belonging to Marconi's Wireless Telegraph Co. and to Lloyd's. That purchase had been amply justified by results. The wireless stations were working with complete success, and within the last three months the number of messages received and sent had doubled, showing that the services of those stations were appreciated by shipowners. He was now holding an inquiry as to the distribution of those stations round the coast, and as to the desirability of opening up new ones in places such as in Newcastle and district where no stations were at present in existence; and hoped to have before long a complete ring of stations all round the coast and parts of Ireland which would be of great service to shipowners, who would therefore be well advised to proceed as rapidly as might be with the equipment of their vessels.

Telegraphs.—The telegraphs also, after several years of decline, had begun to show some expansion. The figures, which had suffered in recent years from the competition of the telephone, now began to show some revival. The Post Office had spent £2,000,000 in laying down underground cables in various parts of the country to protect the telegraphic system from interruption by storms, and that work was being continued, a considerable sum being taken in this year's estimates for the further extension and completion of the underground telegraph service.

On the subject of international penny post he wished it were possible to be able to confer what was undoubtedly a great boon, the extension of their system of penny postage. But he did not think it possible for that question to be considered as though it related only to an arrangement with themselves and a country. The present Imperial loss on Imperial penny postage was £155,000, and it increased as their correspondence increased.

Contractors and Fair Wages.—With respect to the workpeople employed by contractors, the new fair wages clause sanctioned by the House of Commons was, of course, being inserted in all new contracts with the Post Office. They had an inspector continually at work, devoting his whole time to inspecting the conditions of employment of workpeople under contractors working for the Post Office, and seeing that the terms and conditions of the contract were properly observed.

Telegraphists' Cramp.—A committee had been appointed in the last few weeks to investigate the question of telegraphists' cramp. He had long felt that it was a reproach to any industry that the workers should be exposed by its processes to the contraction of disease peculiar to that trade. As chairman of the Departmental Committee on Industrial Diseases, he was instrumental in having telegraphists' cramp scheduled in the bill dealing with compensation for injuries, and now that he was at the Post Office he was eager to adopt any means that science could devise in order to secure what was far better than either compensation or cure for industrial disease—and that was prevention. With respect to operators in the telephone exchanges there had lately been sensational statements in the Press as to the effect upon their physique of the employment on which they were engaged. Grossly exaggerated figures had been published, which on inquiry proved to require to be divided by two or three, or sometimes by ten, in order to give a fair picture of the facts. But the truth remained that the work of the telephone operator was of a character that imposed a certain strain on the nervous organisation, and a medical inquiry into the conditions of employment in the telephonic exchanges, which was conducted by the second medical officer of the Post Office and the principal female medical officer, had reported on the subject. The report reached him two days ago. A number of suggestions for improvement in the allocation of hours, intervals for meals and rest, some small improvements in the instruments, &c., had been made. He had given instructions that the recommendations of the report should be regarded as matter of urgency, and he hoped in the near future to be able to effect any improvement that might be found by the medical officers and technical advisers to be practicable in that branch of the work of the Post Office.

Several members criticised the Estimates, and, in replying,

The ASSISTANT POSTMASTER-GENERAL (Capt. C. Norton) said that in regard to submarine cables, the whole system of telegraphy was in a state of change. With a State system of cables there would be competition with companies and difficulties as affecting departmental relations with those companies, most of them British, and difficulties with self-governing Colonies. A committee had been considering the subject, and the recommendations of that committee were under the consideration of the Department. On the question of municipal powers in relation to the telephone service, he could give no pledge. Every effort would be made to acquire the National Telephone Co.'s undertaking on the best conditions for the public interest, with no payment for goodwill.

Ultimately, the Post Office Vote was agreed to.

Digitized by Google

LC.C. (TRAMWAYS & IMPROVEMENTS) BILL.

Last week a House of Commons Committee, presided over by Mr. Soames, passed the preamble so far as related to the proposed new tramway from New North-road to Southgate-road, on the north side of the Regent's Canal, and the reconstruction of the existing horse tramways from Highbury Corner to City-road and from Finsbury Park to Old-street (via Green-lanes, Southgate-road). The Committee refused the request of the Regent's Canal Co. for a clause obliging the County Council to build a bridge over the canal at New North-road.

The proposal for a tramway from Brixton to Norwood-road, via Effra-road and Dulwich-road, was next considered, and the Improvements committee were unable to agree to a clause binding them to widen the road by taking off a strip of Brockwell Park. Mr. E. White, the chairman of the Highways committee, suggested that the difficulty might be overcome by making a single line for 50 yards, that being the longest distance it was found convenient to work with a single line.

Ultimately the Committee approved a clause providing that unless the Council widened Dulwich-road, Herne Hill, to the full extent the tramway there should be a single line for about 100 yards from the main entrance to Brockwell Park between points marked on the deposited plan.

The Committee also approved the proposal to construct a new tramway, about 1½ miles long, from the southern approach to Putney Bridge, joining the existing line there and passing along High-street, Putney, Putney Bridge-road and High-street, Wandsworth, joining the existing tramway in York-road. The estimated cost of construction was £43,700, but widenings and acquisition of property would cost £167,200. A small supplementary line will connect the new line with the existing line in Lower Richmond-road. The Board of Trade are to decide the question whether the cross-over where the line would join the Tooting and Balham line should be worked as a single line.

L.C.C. (GENERAL POWERS) BILL.

The clauses of this Bill which deal with the smoke nuisance have been further considered by the Local Legislation Committee of the House of Commons, presided over by Sir F. Layland-Barratt.

Mr. H. F. DONALDSON, chief superintendent of ordnance factories, stated that since 1906 the War Office had received no complaints at all from outside as to smoke nuisance at Woolwich. During the past 10 years they had tried at least a dozen appliances for smoke consumption, and investigated something like 40 different systems. They had the strongest possible reason, that of economy, for not emitting smoke if it could be avoided.

Mr. R. R. BANNATYNE, of the Home Office, objected to the proposal in the Bill to extend sec. 24 of the Public Health (London) Act, 1891, so as to include "the chimneys of any factory or workshop, as defined by the Factory and Workshop Act, 1901, belonging to or used by the Crown."

The Committee decided that they could not grant the powers over Government departments asked for in the clause.

Mr. OLIVER L. PEAR, testing superintendent of the City of London Electric Lighting Co., stated that 95 per cent. of the smoke nuisance in London was caused by domestic chimneys. He had made calculations which showed that, while 11,250 tons of smoke were sent annually into the atmosphere from factory chimneys, the amount issuing from domestic chimneys was 250,000 tons a year, while the proportion of tarry matter in the smoke were 4 per cent. and 15 per cent. respectively. The smoke nuisance problem in London would never be solved until domestic chimneys were dealt with.

On Tuesday the CHAIRMAN announced that the Committee had come to the unanimous conclusion that no evidence had been put before them which would justify them in assenting to the omission of the word "black" from the Act of 1891.

WIMBLEDON & SUTTON RAILWAY BILL.

This bill, which has already passed the House of Lords, came before a House of Commons Committee on Tuesday, Mr. Ashton, M.P., presiding.

Mr. H. LLOYD, K.C., for the promoters, said the proposal was to extend the District Railway from Wimbledon to Sutton. The scheme was promoted by local landowners to the value of about £750,000 in the neighbourhood, many of whom would be prepared to take payment in shares for land required for the line, while some would give land. It was proposed to raise £350,000 capital with the usual borrowing powers. The estimated cost of construction was £311,554. The only opposition was from the L.B. & S.C. Co. The L. & S.W.R. Co. had agreed to the junction at Wimbledon and the District Company were willing to work the traffic electrically, their trains running through Wimbledon.

Evidence in support of the bill was given by Mr. H. R. Searles-Wood, chairman of the promoting syndicate, and by Mr. W. E. R. Innes, chairman of the Merton Park Estate Co.

Mr. R. H. SELBIE, general manager of the Metropolitan District Railway, said the proposed line (5½ miles in length) would serve a present population of 100,000, would be a cheap railway to work, and he thought (allowing £23,100 working expenses on gross receipts £42,000) a net revenue of £18,900 might be expected, increasing with the growth of population.

Mr. W. V. GRAHAM, C.E., engineer for the scheme, said that the proposed stations would be in most instances a mile from the existing stations on the L.B. & S.C. Railway from Sutton to Wimbledon via Mitcham. The estimated cost of the works and land was £311,554. In the estimate of £181,140 for works, the electrification of the line (costing probably £40,000) and the provision of rolling stock had not been included. It was usual to make provision for equipment and rolling stock by the exercise of borrowing powers, and these matters would be subject to arrangement with the Metropolitan District and L. & S.W. Companies in regard to goods traffic.

Sir G. GIBB thought the proposed line would be a useful addition to the railway accommodation for the outer zone of London. It would not injure the Brighton Company's traffic and their service to Victoria and London Bridge. It would be an advantage to have the through connection at Wimbledon for Earl's Court. The District Company intended to enter into an arrangement for working the proposed line.

Sir J. WOLFE BARRY, K.C.B., said the line was well conceived for the purpose of opening up that new residential district. The estimates had been examined by his staff and found sufficient. Existing requirements perhaps would not support the line, but the district would rapidly develop.

At the suggestion of the Chairman the promoters, having formally proved a resolution from Carshalton in favour of the Bill, did not put forward further evidence, and the case for the Bill closed.

Mr. W. FORBES, general manager for the L.B. & S.C. Railway Co., explained the arrangements of his company for the London and Sutton traffic. There were quicker trains in the morning and evening. The journey to Victoria by the proposed line would occupy 44 minutes. His company contemplated further electrification of their lines in which Sutton would be included, but he did not find that there was a demand for a more rapid service between Sutton and Wimbledon. He had tried it a few years ago, and in the present month had been running motor trains in addition to the regular service, but had only carried an average of four passengers per train. There was not the traffic to cater for between Wimbledon and Sutton. His company having incurred large expenditure and being prepared to meet all public requirements, should, he urged, be left alone.

SMETHWICK PROVISIONAL ELECTRIC LIGHTING ORDER.

On Wednesday a Select Committee of the House of Commons, presided over by Sir Henry Kimber, considered the Electric Lighting Orders (No. 1) Bill, which confirms various provisional orders made by the Board of Trade, including the Smethwick order.

Mr. FREEMAN, K.C., for the promoters, said the bill was to confirm a provisional order authorising the transfer of an order from the Birmingham & Midland Tramways (Ltd.) to the Shropshire, Worcestershire & Staffordshire Electric Power Co. In 1898 an agreement was entered into between Smethwick Council and the Birmingham Co. by which the company was to work the order, and in 1906 the Board of Trade drew the attention of Smethwick to the fact that the action practically amounted to the divestment of the order, and they suggested that it should be transferred to the Tramway Co. In 1907 that transfer was carried out. It was, however, agreed that it should not be done without the sanction of Smethwick Corporation, and such consent was not to be "unreasonably" withheld so long as the company who took the order were reliable and responsible. The Shropshire Co. now sought to take over the order. At an inquiry held by the Board of Trade in 1908 all the details were considered, and every question raised was satisfied, except a personal one as to whether the Town Clerk of Smethwick should be allowed his expenses. The Corporation stated that they had reason to doubt whether the pecuniary position of the Shropshire Co. was of such a satisfactory nature as to warrant their undertaking the powers, duties and obligations of the order. He would point out that the company, before taking over an order, had to raise a definite sum, and the Shropshire Co. had the certificate of the Board of Trade to that effect.

Mr. SIDNEY MORSE gave evidence in support of the Order.

Mr. ERSKINE POLLOCK, K.C., addressed the Committee on behalf of petitioners, and said he did not object to the transfer under certain conditions, but they wanted to be safeguarded with regard to the price to be charged for street lighting, and that words should be put in the order so as to make it clear that the transfer should not absolve the Shropshire Co. from various obligations entered into with Smethwick Corporation.

The Committee passed the preamble, and asked Mr. Pollock to bring up a clause which would satisfy both parties. The Committee would consult the Board of Trade and the speaker's counsel before giving their decision.

Ardrossan and Cambuslang Provisional Orders.—The Court of Referees of the House of Commons have disallowed the locus standi of the Caledonian & Glasgow and S.W. Railway Companies in regard to the Bill confirming the provisional electric lighting orders for Ardrossan and Cambuslang, except in relation to the provisions as to carrying electric cables over railway bridges.

North & South Shields Electric Railway Bill.—This bill has been withdrawn.

LEGAL INTELLIGENCE.

Wireless Telegraph Patents.

Last week the case of Taylor *v.* W. Bingham was mentioned to Mr. Justice Parker by Mr. Walter, K.C., who stated that the action related to certain wireless telegraph patents, and he had a motion for an interlocutory injunction. He had, however, arranged with Mr. Mark Romer, K.C. (who appeared on the other side) for the motion to stand over until trial.

His lordship assented to this.

MUNICIPAL, FOREIGN & GENERAL NOTES.

APPOINTMENTS VACANT AND FILLED.

The Governors of Robert Gordon's Technical College (Aberdeen) are about to appoint an engineer graduate of distinction as head of the engineering department of the college. Salary £500 per annum. Applications to the principal (Mr. Chas. Stewart, M.A.), by July 16. See also an advertisement.

A competent selling electrical engineer is wanted at once for India. See an advertisement.

A foreman is required with experience in pivoting, balancing, and calibrating delicate moving coil instruments. Applications to Mr. R. W. Paul, Newton-avenue Works, New Southgate, London, N. See advertisement.

A first-class tracer is wanted at electrical engineering works at Chiswick. See an advertisement.

Applications will be received until Sept. 10 for appointment to the Henry Overton Wills Chair of Physics at Bristol University. Salary £600 per annum. Particulars from the Registrar.

A senior demonstrator is required in the technical optics department of the Northampton Institute, London. Salary £175. Forms, &c., from the Principal, to whom applications by July 5.

A radiographer is required at the Hospital for Consumption and Diseases of the Chest, Brompton, London, in succession to Dr. Greg. Honorarium 50 guineas per annum. Applications by July 7.

Owing to Mr. C. W. Salt having recently resigned his position as chief assistant electrical engineer at Bradford to take up the position of chief electrical engineer of Torquay municipal electricity undertaking, Bradford City Council, acting on the recommendations of the Electricity committee, have appointed Mr. Harry S. Ellis, assistant electrical engineer, to be deputy electrical engineer and manager, and Mr. J. H. Schnauber, chief draughtsman, has been appointed assistant electrical engineer.

Mr. J. C. Johnson has been appointed senior charge engineer at Willesden, and Mr. J. D. Ravenscroft is to take Mr. Johnson's place and a third assistant is to be appointed.

Mr. James Robinson, M.Sc., Ph.D., has been appointed junior lecturer and demonstrator in physics at the University of Sheffield.

Mr. Thomas Thompson, B.Sc. (Eng.), B.A., has been appointed assistant engineering lecturer at the Municipal Technical Institute, Coventry.

EDUCATIONAL NOTICES.

City and Guilds of London Institute.—The entrance examinations of the City and Guilds Central Technical College, Exhibition-road, S.W., and the City and Guilds Technical College, Finsbury, E.C., are held in September, and the sessions commence in October.

Both institutions provide courses of instruction in engineering, chemistry, mechanics and mathematics, &c. Particulars of entrance examinations, scholarships and courses of study may be obtained from the respective colleges or at the head offices of the Institute, Gresham College, Basinghall-street, London, E.C. The Central Technical College is intended for higher technical instruction for day students not under 16 years of age, preparing to become civil, mechanical or electrical engineers, chemical or other manufacturers and teachers. The college is a school of the University of London, and forms the engineering section of the Imperial College of Science. The courses of the study for the associateship of the Institute cover a period of three years.

The City and Guilds Technical College at Finsbury (London, E.C.) is designed for day students preparing to enter engineering and chemical industries and for those who have already served an apprenticeship and also for evening students. The day courses in mechanical or electrical engineering cover two years and those in chemistry three years.

Northampton Polytechnic Institute.—The silver medal offered by the Women's Aerial League to the best student in the pioneer courses in aeronautics held during the session 1909-10, has been awarded to Mr. Duncan George, Mr. E. R. Moffat being proxime accessit.

Extended courses of a more complete and practical nature are being arranged for next session, and Mr. F. Handley Page (Handley Page, Ltd.) has been appointed to take charge of these courses. In addition, there is under consideration the establishment of full-time day courses in aeronautical engineering, extending over four years, and similar to the well-known day courses in electrical and mechanical engineering established some years ago. Fuller particulars will be ready shortly.

Heriot-Watt College (Edinburgh).—This college provides theoretical and practical training for mechanical, electrical and mining engineers, technical chemists, brewers, &c., and printers and publishers. The training for engineers consists of three years in the college and a three years' apprenticeship on the "Sandwich" system in a local engineering works. The course in mining extends over two years, and the training is also recognised by the University of London for the B.Sc. degree in mining. Complete courses of instruction, extending over four years, are provided for students studying for the fellowship of the Institute of Chemistry, &c. An entrance bursary of £25 will be offered for competition on Sept. 27 and 28 next. Particulars of fees, &c., may be obtained from the principal, Mr. A. P. Laurie, M.A., D.Sc.

BRITISH AND COLONIAL.

Aberdare.—The Council have decided to promote a Bill to authorise the construction and working of an electric tramway from the cemetery to Cwmaman and to confer powers to carry out other improvements.

Acton.—On Wednesday the Council decided by 11 votes to four that the necessary notice be given to terminate at December, 1913, the agreement with the Metropolitan Electric Supply Co. for the supply of electricity in bulk to the Council. The proposal to hand over the Council's electricity undertaking to the company was rejected by 14 votes to six.

Amalgamated Society of Railway Servants.—Mr. J. E. Williams has been elected secretary of this society in succession to Mr. R. Bell.

Australasia.—The "Australian Mining Standard" states that a meeting of Kapunda (S. Australia) ratepayers is to be called to discuss the question of lighting the town electrically.

Customs.—Under an order dated June 7 the list of goods which may be imported into Canada duty-free includes fuse heads of metal foil and cardboard imported by manufacturers of electric fuses for use only in their own factories in the manufacture of such fuses.

Dewsbury.—The new Council schools at Batley Carr are to be wired.

Earnings of Workmen in Electricity Supply, Tramway and other Public Services.—A report of an inquiry by the Board of Trade into the earnings and hours of labour of workpeople in public utility services in 1906 states that no statistics are available showing the total number of persons engaged in such services, but returns have been received from nearly all local authorities directly employing labour and from most of the private companies of importance, and the number of persons with regard to whom returns have been obtained is 268,000.

The average earnings of workpeople in the electricity supply service was 29s. 6d. and of men only 31s. 7d. per week; in the tramway and omnibus services (combined) 29s. 3d. and 30s. 6d. respectively. Wages in the gas service were 31s. 7d. for all persons and 32s. 6d. for men only, an increase of 18 per cent. compared with the year 1886, but no comparison is given with 1886 in regard to the electricity and tramway and omnibus services. The average hours in a full week's work in the electricity supply service were 51·9 (compared with 52·6 in the gas service) and in the tramway and omnibus service 58·7. The average number of holidays allowed (to persons allowed recognised holidays) was 10·4 in the electricity, 7·4 in the gas and 6 in the tramway and omnibus services. A footnote states that in the gas and the tramway and omnibus services there were no recognised holidays allowed in a number of cases, and if all the workpeople were included the average would be 6·6 days in the gas and 3·8 days in the tramway and omnibus services. The average earnings in the electricity supply service in the whole of the U.K. were: For foreman 48s. 4d., meter inspectors 30s. 11d., switchmen 31s. 11d., jointers 38s. 11d. and wiremen 35s. 11d. per full week. In London the comparative figures were: Foremen 52s. 3d., meter inspectors 32s. 6d., switchmen 35s. 9d., jointers 41s. 7d. and wiremen 36s. 7d. The average earnings of certain classes of tramway and omnibus workers was as follows, for the whole of the U.K.: Motor tram drivers 30s. 8d., horse and cable tram drivers 33s. 9d., omnibus drivers 35s. 9d., conductors 26s. 11d., regulators 33s. 1d. For London the wages for the same classes were 32s. 4d., 34s. 9d., 38s., 30s. 9d and 38s. respectively.

Electricity in Mining.—The report of the directors of the Maltby Main Colliery Co. states that a portion of the electric power installation is at work, and the remainder of the plant required in the near future is in process of erection. The permanent electric pumping plant has been erected and is at work. The fan and engines are ready for starting immediately the shafts are down to the coal.

The new electric power and lighting plant at the Deep Navigation Ocean Collieries, Treharris, was formally started by Mrs. Davies, wife of Mr. D. Davies, M.P., on the 23rd ult. Electric current will be used for surface and underground lighting, pumping, &c.

Gloucester.—On Wednesday the City Council increased the salary of the general manager of the tramways (Mr. L. Johnston) to £350.

Digitized by Google

Hackney (London).—The borough electrical engineer (Mr. L. L. Robinson) has denied a statement in the Press to the effect that the Council had decided to replace their electric arc lamps with gas lamps.

For a number of years (states Mr. Robinson) the more important main streets in Hackney, extending some 20 miles, have been lighted by electric arc lamps, which have given thoroughly satisfactory results. There is not the slightest inclination on the part of the Council to have this electric lighting replaced by gas lighting. In the less important streets gas has not yet been displaced. A few months ago, in consequence of the enormous economy in electric lighting effected by the introduction of the metal filament lamp, the Electricity committee were in a position to offer a lower price for this "side street" lighting than was charged by the gas company, but unfortunately they could only make their offer in respect of some 600 lamps, because supply mains are not yet laid throughout every street in the borough. Nevertheless, the threatened competition of the electric light has had a beneficial result, in so far as that it has drawn from the gas company an offer to replace all the existing upright mantles in the public street lamps with inverted mantles, and to reduce the bill by some £2,000 per annum, provided they got the contract for the whole of the existing lamps for five years.

Howth and Sutton (co. Dublin).—At a recent meeting of ratepayers the electric lighting scheme of the Improvements committee was approved.

The scheme has been prepared by Messrs. W. Coates & Co., and it is proposed to request the County and District Councils to grant wayleaves for laying cables along the roads, and the firm undertake to finance the scheme and to supply electricity at a charge not exceeding 6d. per unit to consumers.

Islington (London).—Sir Alex. Kennedy, who has reported upon the desirability of increasing the capacity of certain electricity supply mains, is of opinion that the present high-tension feeders to four areas are seriously overloaded and that the extensions proposed by the borough electrical engineer (Mr. A. Gay) are necessary.

Sir Alex. Kennedy also considers the adoption of sub-stations for present and future extensions is very advisable to enable the Council to obtain satisfactory regulation of their supply pressure, and to take advantage of the economical working of transformers so placed. At the same time the low-tension distributors from these sub-stations should be laid so as to make use of the three-wire system and higher voltage which is already successfully in use in other parts of the district.

The Electricity committee report that they are satisfied from the report of Mr. Gay that it is necessary to carry out the works indicated, at an estimated amount of £19,872, without delay.

Mr. Gay has reported that it is necessary, in order to comply with the regulations issued by the Home Office under sec. 72 of the Factory Act, to provide a new main switchboard, at a cost of £3,000, and the Lighting committee has decided to invite tenders for the work.

Kingsbury.—The Council have approved the action of the chairman (Mr. J. Diaz) in communicating with the North Metropolitan Electric Power Supply Co. offering to continue negotiations for the supply of electrical energy for public and private lighting.

Leicester.—It was reported to the Corporation on Tuesday that the Gas and Electric Lighting committee had considered the effect of the recent judgment of Mr. Justice Neville in regard to the municipal electrical fittings department.

After carefully considering the matter the committee came to the conclusion that, as there were other Corporations likely to be affected by the decision, before taking any further steps they should be communicated with. The committee will meet again shortly to consider the course to be adopted.

The chairman of the committee (Ald. Smith) said that they thought the present was an opportune moment for suggesting a change in the administration of the management of the gas works. The committee were of opinion that there was no insurmountable difficulty in separating the gas from the electricity department. The committee had also considered the matter from the point of view as to whether the present electricity works at Aylestone and Belgrave-road should be run as separate concerns, or whether, in the public interest, there should be an amalgamation of the two under one committee. The capacity of the plant at Aylestone was equal to 4,400 kw. The maximum load on the station in 1909 was 1,962 kw., so that if a 1,000 kw. set were allowed as reserve, there would remain one 1,000 kw. set available for power or other purposes. The sales for lighting last year reached 1,546,635 units, and for power 405,305 units, and the cost per unit worked out at 3½d. per unit in 1907, against 3¼d. in 1909. There had been a considerable decrease in revenue since the introduction of metal filament lamps. Since 1907 the total revenue had fallen from £33,882 to £28,832, a difference of £5,000, while the net profit had only dropped £2,600. The total generating capacity of the plant at Belgrave was 2,500 kw., and the total output last year was 6,616,650 units. The total works cost was ½d. per unit. The output for the current year would be at least 8,000,000 units. They were supplying 1,500,000 units per annum for power alone, and this figure would increase considerably before the end of the year. The total horse-power of motors coupled up this year amounted to 759 H.P., and the total up to the end of December last year was 669 H.P., making a grand total of 1,428 H.P. The advantages of unification might be briefly summarised as follows:—

(1) The whole electricity production and supply for lighting and power would be under the control of one special committee, whose duty it would be to supply electricity at the cheapest possible rate; (2) it would stop friction between committees, and abolish insane and unnecessary competition; (3) consumers and users of light and power would have free choice in taking alternating or direct current—whichever suited them best—at equal rates; (4) the present ducts, cables and machinery could be more economically used for the present purposes and future extensions of supply; (5) one central office—part of the present gas offices being available—could be extended, where all requiring electricity for light or power could apply; (6) amalgamation would mean the retention of the present engineering and clerical staffs, with less friction and better control and economy of management.

The committee's recommendations were adopted.

Liverpool Tramways.—To meet the heavy call on the tramway service in Liverpool for the conveyance of passengers to and from the Royal Agricultural Society's Show held at Wavertree last week, we learn that 200 additional cars were provided. During the greater part of the five days of the show 150 of these extra cars were in use, 50 being held in reserve to meet any exceptionally heavy demand. The consequence was that the very heavy traffic was handled in a most admirable manner, and there was no waiting or crushing at any point of the different routes or at any of the entrances to or exits from the show. Much credit is due to Mr. C. W. Mallins, the tramways manager at Liverpool, for the effective arrangements made to meet this particularly exacting demand. We know that the excellent service was highly appreciated by the visitors to the show, whose time was greatly economised thereby.

Llandudno.—The salary of the electrical engineer (Mr. Harold Morton) has been increased.

London County Council.—On Tuesday it was agreed to allow Poplar to alter the terms of their electricity loans and make the repayments quarterly.

New Tramways.—The Highways committee's recommendation to expend £35,250 on capital account for the construction of authorised tramways from Battersea Park-road to King's-road, Chelsea, was agreed to.

Marylebone (London).—The Electricity committee report that the general manager (Mr. A. Hugh Seabrook) has advised that in future the annual charge in respect of the use of electricity for all domestic residential purposes (other than lighting) should be discontinued, and the annual charge for lighting considered to cover all uses of electricity.

The proposed reduction will only apply to private consumers who adopt the "telephone" system of charging in their residences. The committee are satisfied that, though there will be a trifling decrease in revenue, the increased business will recoup the concession.

42 public lamps have been converted from gas to electricity, making a total of 2,262 electric lamps.

Monaghan (Ireland).—The Council have passed a resolution in favour of an electricity supply scheme.

Nuneaton.—The Highways committee are not prepared to supply the c.-i. columns and brackets for future street lighting extensions, as recently suggested by the L.G. Board inspector, and the Board have been asked to sanction the raising of £240 for street lighting extensions.

Ald. BATES, in moving the adoption of the report, said that when the big flywheel broke at Messrs. Fielding & Johnson's cotton factory the electricity department were asked to supply about 300 H.P. of electrical energy, and that had been promptly supplied, thus enabling the factory to continue working without much delay. Otherwise the factory would probably have been idle for several weeks and 400 workpeople thrown out of employment. He thought the department was to be congratulated on the expeditious way it had coped with that work.

Personal.—Mr. G. H. J. Hooghwinkel, M.I.M.M., M.I.E.E. (Messrs. Hooghwinkel, Anthony Brown & Partners), is leaving for the West Indies and Mexico on July 6 on professional business.

Poplar (London).—The Finance committee has been asked to report upon certain proposals of the electrical engineer (Mr. J. H. Bowden) for a revised system of charging, with a view of securing greater diversity of load.

In March, 1909, the Council approved the wiring of 25 houses at a tariff of 12½ per cent. on the Council's cost of installation to cover interest, depreciation and repairs, with a further charge of £4 per annum per kilowatt in respect of the capacity of the lamps connected, and £1 per kilowatt for heating, &c., plus ½d. a unit in each case for all current consumed, lighting in cellars, lavatories, &c., not extensively used at time of maximum load, being charged at the same rate as for heating. The Electricity committee report that the results appear to have been satisfactory, and they are of opinion that this class of installation may be usefully extended. It is also suggested that a similar system of charging should be adopted in respect of lighting business premises, but in these cases, while the charge for consumed current will remain the same, it is proposed to fix the rate per kilowatt installed at £13 for inside lighting and £6. 10s. for outside arc lighting, the latter demand coming only partially on the peak of the load.

With regard to power consumers, it is proposed to establish a general rate of £4 per kilowatt demanded, plus ½d. per unit for all current consumed, discarding the rate of £3 per kilowatt and 8d. per unit, and to

Digitized by Google

offer rebates to large consumers. The committee recommends that Mr. Bowden be authorised to wire a number of premises, not exceeding 50, for domestic and business supplies on the terms and conditions stated, at a cost not exceeding £20 for any one installation; also that the proposed rate for direct-current power be £4 per kilowatt demanded, with ½d. per unit for current supplied, subject to rebates.

Preesall (Lancs.).—The Council are considering electric lighting schemes submitted by the Trafford Electric Works Co. and Mr. Swarbrick, Leigh.

Presentations.—The shareholders of the Lymington Electric Light & Power Co. have presented a silver cigarette case to Mr. Glynn Slater, Engineer and Secretary, who has been appointed engineer and manager of the Hamilton Electricity Works.

The staff and employés at Swadlincote of the Burton-on-Trent & Ashby Light Railway Co. have presented a pair of bronzes to Mr. R. O. Baldwin, traffic manager, who has accepted a similar post at Bournemouth.

Last winter Hanley Education committee initiated a course of electrical engineering lectures at the municipal secondary school. Practical demonstrations and testing work were also carried out at the power station (by permission of Hanley Electricity committee). The whole course, lasting from September to April, was under the auspices of the City and Guilds of London Institute.

Mr. C. H. Yeaman, borough electrical engineer, was the lecturer and demonstrator, and on Friday evening last the students presented Mr. Yeaman with a silver fountain pen as a slight appreciation of the indefatigable and thorough manner in which he had conducted the lectures.

Mr. Yeaman, who was taken by surprise, thanked the members for their useful present, and said that it gave him great pleasure to take up work of that kind and help anyone who took a real interest in the subject, and strove to become efficient, remarking that it was a kind of recreation to himself after the usual business of the day.

Rail-less Trolley Traction.—The manager of the Plymouth tramways (Mr. C. R. Everson) has reported to the Tramways committee on the exhibition of the rail-less trolley system of traction recently given at Hendon.

Mr. Everson states that the experimental running of the car was pronounced to be very satisfactory. He was favourably impressed, and convinced that whenever the Council considered the question of meeting the public requirements of places like Laira and Crownhill, that mode of traction would be very suitable for connecting up such places, to act as feeders to their present tramway service.

Consideration of the report has been deferred.

St. Pancras (London).—Tenders are to be invited for the temporary boiler plant required at the King's-road electricity works to provide for next winter's demand.

Southend.—The Council have applied for a loan of £2,552 for additional feeders.

The salary of the borough electrical engineer and tramways manager (Mr. R. Birkett) has been increased from £500 to £700, rising to £1,000 by £30 a year.

Tottenham.—In regard to the public lighting, the North Metropolitan Electric Power Supply Co. have asked the Council to allow them to tender for a minimum of five years for the whole district, but they may tender only for three years for those portions where their mains are laid.

The Tottenham Gas Co. has been asked to reduce the charge for public lamps, and in reply the secretary has stated that the price is at present so low compared with the charge to the general public that there is little margin for reduction. Anticipating, however, that during the next 10 years economies would be made in gas manufacture, the company offer a reduction equal to 2s. per lamp, with 1·61d. per lamp per night for supplying gas mantles, &c., for cleaning each lamp weekly, for lighting and extinguishing it and for supervision, &c.

Both communications have been referred to a committee.

Victoria-Crystal Palace Tube Railway.—Particulars have been published of an amended scheme for the construction of a tube railway from Victoria to the Crystal Palace.

It is proposed that the terminus should be at the Penge entrance to the Palace instead of at Upper Norwood. The line will be 6¾ miles in length, with a branch line of 1½ miles running to the Elephant and Castle from a point near Walworth-road. The stations on the amended scheme will be Penge, Upper Sydenham, Lordship-lane, Dulwich, East Dulwich, Denmark Hill and Camberwell, where it branches off to Walworth, and the main line goes on to the Oval, the Albert Embankment and Victoria. There is a further suggested line which would carry the railway on to Cricklewood, going through Marble Arch and Hyde Park Corner. The cost of the new tube will be £340,800 per mile.

It is also stated that the directors of the London, Brighton & South Coast Railway Co. will next month recommend the extension of electric traction to that portion of the line between Peckham Rye and the Crystal Palace.

Wireless Telegraph Notes.—Capt. Howland, of the Norwegian Navy, is about to visit London and other cities, in order to demonstrate an improved wireless telegraph apparatus, designed to more effectually systematise wireless messages.

It is announced that the War Office are in negotiation with the Marconi Wireless Telegraph Co. for the purchase of about 300 sets of a simple portable wireless telegraph apparatus, the invention of Major Beddington, of the Yeomanry. This apparatus can be erected and completed for transmitting messages in about 15 minutes. It is light and easily transportable.

The Postmaster-General has under consideration the complete linking-up of the islands on the West Coast of Scotland by means of wireless telegraphy, there being little or no traffic to justify laying a submarine telegraph cable on a coast where the submerged lines would be liable to frequent interruption.

The Under Secretary of State for India in the House of Commons on Wednesday stated that the scheme for the establishment of certain inland wireless telegraph stations in India had been approved.

Workhouse Lighting.—The House committee of Hungerford Guardians are preparing a report on the electric lighting of the workhouse.

Annual Outing.—On Saturday last the employees of Messrs. Siemens Bros. Lamp Works (Dalston, N.E.) visited Brighton for their second annual outing. The weather was showery in the morning but cleared later and became splendidly fine. The party numbered over 500, and left London Bridge at 7 a.m.

An excellent luncheon was provided by the company at the Aquarium.

A vote of thanks to the committee and Mr. Hicks (the secretary) for the success of the outing was proposed by Mr. Holmes and carried with acclamation. A musical programme was provided at the Aquarium. The party then dispersed and many of the surrounding places of interest were visited. The outing proved thoroughly enjoyable and successful.

FOREIGN.

Brazil.—Vice-Consul Simpson states that the company owning the electricity supply works at *Maceio* is in a healthy condition and has largely increased its plant recently.

Vice-Consul Garcia says the town of *Natal* is lighted by acetylene gas, but the introduction of electric light is under consideration.

Consul W. H. M. Sinclair states that electric lighting is making considerable headway in *Bahia*. Fittings are, as a rule, very plain and all installations are in the hands of the lighting companies. Fans are at present little used.

France.—The report of Consul A. McMillan on the *Nice* district for 1909 states that it is probable electric traction will be used on the Nice to Antibes and the Vesubie to St. Martin Vesubie tramways before the end of the current year.

The development of the network of telephones in the Alpes Maritimes continues to make progress, a number of communes having been connected with Nice.

Consul R. Macdonald states, in his report on the *Bordeaux* district, that the imports of machinery and parts of machinery (exclusive of agricultural and sewing machines) from the U.K., amounted to 1,407 tons, a slight decrease compared with 1908. There was a decrease in dynamos and an increase in machine tools.

Franco-German Telegraphs.—It is announced from Paris that an agreement has been concluded between the French and German Governments with regard to the common use of their respective submarine telegraph cables at any time that accidents of a technical or other nature interfere with the normal working of the service.

Holland.—The "Vaderland" states that Dordrecht municipality have decided to construct an electrically-operated swivel bridge at a cost of about 98,000 florins (£8,166).

International Competition of Practical Telegraphists.—The Italian Minister of Posts and Telegraphs has issued invitations to the Government Telegraph Administrations and the telegraph companies adhering to the International Telegraph Convention, the Imperial Chinese Telegraph Department, and the other principal private telegraph companies to participate in a competition in the transmission and reception of messages with Morse, Hughes and Baudot apparatus at the Turin International Exhibition. A list of the money and other prizes and medals which will be awarded is to be published later. Signor Ciuffelli, Minister of Posts and Telegraphs, Rome, will be pleased to receive notices of intention to compete.

Japan.—The report of Consul A. M. Chalmers for 1909 states that the imports at *Nagasaki* included steam engines and boilers £8,769 (compared with £728 in 1908 and £40,367 in 1907), steam turbines £1,169 (against £43,623 and £52,861), dynamos £1,561 (£8,542 and £20,132).

Acting-Consul W. M. Royds states that electric light was first seen in *South Formosa* in December last, when a power station was established at Chikushimon to supply electric light and power to the towns of Tainan Anping, Hozan and Takow.

Digitized by Google

H.M. Commercial Attaché at Yokohama (Mr. E. F. Crowe) states, in his report for 1909 that there has been a boom in electric tramway undertakings, particularly in the district round *Osaka*, and *Kobe*, and in the south of Japan. Mr. Crowe advises that great caution should be exercised before attempting to take part in any proposed new ventures of this kind, and there are several engineers on the spot whose business it is to watch these enterprises, and who know long before the general public if anything at all good is forthcoming. Orders for machinery, rolling stock, &c., are in most cases accompanied by requests for very easy payments.

Imports of machinery to Japan were valued at £2,072,400 (compared with £3,498,600 in 1908). The imports of machinery from the U.K. were £1,409,000 (against £2,070,400, and £158,200 in 1908 and 1907 respectively), from the U.S.A. £382,500 (against £916,200 and £851,100), from Germany £252,800 (£453,400 and £328,000), France £12,000 (£18,300 and £41,900); other countries £16,100 (£40,300 and £24,600). The total imports of dynamos and motors were valued at £184,400 (against £209,200 in 1908) and of other electrical machinery £121,800 (£170,600); telephones £12,200 (£11,500); steam-engines £72,000 (£180,300); gas, oil and hot air engines £39,100 (£98,700); steam turbines £23,700 (£76,500), and lifting machines £189,900 (£116,200).

Madeira.—H.M. Consul (Capt. J. Boyle) states that the concession recently held by the Madeira Electric Lighting Co. has been transferred by the Camara to the *Madeira* Electric Lighting Co. (1909) Ltd., which has been registered in London and Portugal. The present generating plant is to be scrapped and the latest type of machinery put in. Afterwards the mains will be extended to the whole of the Concelho of Funchal. There is a local advisory board of directors, with Mr. A. Barron, M.I.C.E., as engineer-in-chief. It is believed that the telephone concession is to be taken over and worked by the Government, and that the cost per telephone will be about 22 dol. 500 reis (£4. 12s.) per annum, with an additional charge of 6 dol. (£1. 4s.) at the time of installation.

Mexico.—Consul L. J. Nunn states that large sums will be spent in the near future by the *Vera Cruz* Terminal Co. in the equipment of hydraulic cranes for the water front work, and electric cranes for warehouses, &c.

Consul H. W. Wilson (*Tampico*) says an electric 30 ton crane has recently been erected on the Fiscal Wharf and can travel the whole length of the wharf (about half a mile).

Vice-Consul J. B. Sanford states that the Monterrey Railway Light & Power Co., by arrangement with the City Council, are about to lay 3 kw. (1¼ miles) of underground cable to supply light and power in the main business portion of *Monterrey*. The Company is remodelling its plant and installing five steam turbo-generators of 500 kw., which will supply current for lighting, tramways and motive power.

Roumania.—Vice-Consul Pyke states that the Dock Administration at *Galatz* are removing the steam cranes at present in use to up-river ports, and will replace them by eight electric cranes.

Vice-Consul Watson says an electric light installation has been introduced at the Port of *Sulina*.

Russia.—The report of Consul P. Stevens on the *Batoum* district for 1909 states that it is intended to construct an electric railway from Vladikavkaz over the main Caucasas Pass to Tiflis. It is also reported that it is proposed to lay an electric line between Sochi and Tuapse and the Black Sea coast. Batoum municipality are considering a scheme for electric tramways. Mr. Stevens points out that any decisive and final action with regard to these schemes must emanate from St. Petersburg, and therefore engineers and capitalists who may wish to engage in such enterprises should communicate with the Government there.

Vice-Consul McDonell (*Baku*) says the Baku municipality have raised a loan of about £2,842,000, of which certain sums have been set apart for the electric lighting of the town and the electrification of tramways. Foreign tenders will be invited. For the public lighting 960 arc lamps will be required, but it has not yet been decided whether the municipality will erect their own station or come to an arrangement with the existing power company.

ELECTRICITY SUPPLY AND TRAMWAY ACCOUNTS.

Belfast.—The annual report of the manager of the tramways department (Mr. A. Nance) for the year ended March has been issued.

The revenue was £203,874. 16s. 10d., and the working expenses £107,335. 1s. 5d., or 52·62 per cent. of gross revenue, compared with 55·87 for 1909. The receipts show an increase of £8,831. 15s. 6d., and represent 9·64d. per car-mile run. The passengers carried included 4,230,814 ½d. fares (persons under 14 who are not allowed to carry luggage or parcels), 38,340,186 1d. fares (87·73 per cent.) and 3,776,591 2d., total 46,347,591. The revenue charges were £50,500, leaving a balance of £50,000, which is to be devoted as follows: Depreciation £13,000, sinking fund £23,000, statutory reserve £14,000.

ELECTRICITY SUPPLY TABLES AND DATA.

This Valuable Set of Tables and Engineering Data relating to Electricity Supply and to Electric Traction on Railways and Tramways in the United Kingdom, the Colonies, and some important places abroad, is now ready, and can be obtained complete in handy book form, price 6s. 6d. post free, or on very hard paper for rough or constant use, price 8s. 6d. post free. A complete Index is included.

Blackburn.—The total revenue of the electricity department for the year ended March 25 was £36,716, and included £33,526 net from the sale of current for private public and lighting, traction and other public services.

Working expenses came to £16,142. Gross profit was £19,574, and after paying interest on loans, income tax, sinking fund, &c., transferring £2,000 to reserve for depreciation, there was a net profit of £1,387. 11s. 5d. (against £976), which has been carried to reserve. Battery and booster extensions were carried out at a cost of £2,388. 19s. 3d. out of reserve, and the balance of this fund is now £3,364. Gross capital expenditure is £275,594, an increase of £6,189. 4,308,005 units of current were sold (against 4,212,300), and of these 346,865 (344,132) were supplied to the public lamps (208 arcs and 478 incandescents), the balance being sold by meter. The maximum supply demanded was 3,000 kw. (against 2,600 kw.)

In the report of the borough electrical engineer (Mr. P. P. Wheelwright) it is stated that depression in local trade has adversely affected the development of the light and power departments; and the improved financial result is due to the reduced cost of production (0·05d. per unit sold), brought about by the more economical and efficient working of the generating station. There was an increase of 194 in the number of consumers connected. The motor hiring department installed during the year 14 motors (of 49 B.H.P.), in addition to motors totalling 340 B.H.P. owned by consumers. The total connections for motors, heating and lighting in equivalent 30-watt lamps amount to 195,973, an increase of 11 per cent.

Gloucester.—The accounts of the electricity department for the year ended March last show capital expenditure £91,039 (increase £704). £89,158 has been borrowed and £17,591 repaid and placed to sinking fund.

Revenue was £12,806 (against £12,354 in previous year), total expenses £6,300 (£6,738) and gross profit £6,506 (£5,616). Interest required £2,808 (£2,775) and instalment of loans and sinking fund contribution £2,855 (£2,830). £56 has been transferred to capital account, and the balance carried forward is £584 (against £202 from previous year). Units sold were 851,450 for lighting and 600,380 for traction. The total maximum demands were 700 kw. for lighting and 390 kw. for traction.

Hull.—The accounts of the electricity supply department were approved by the Electric Lighting committee at their meeting last week.

The total revenue for the year ended March 31 was £53,839, including £29,915 from the sale of current by meter for lighting and £20,489 for power, and £701 for public lighting. Total expenditure (£27,030) included £14,762 for cost of generation, £5,028 for distribution, £2,874 for management, £1,551 for rents and rates, £1,105 for purchase of meters, £750 for switchboard renewal, £619 for show room and £274 for public lamp maintenance. The gross profit was £26,809; interest on stock, short loans, &c., absorbed £11,795 and loan instalments £11,983. The net profit, after allowing for income tax, was £3,289, but £855 was devoted to meeting portion of the capital outlay on show room and stores equipment, &c., leaving £2,438 to be carried to reserve. The capital expenditure is £398,363, an increase of £8,886. 13s. 11d. during the year. The works cost was 0·75d. per unit (against 0·83d.); the total working cost was 0·94d. (against 1·03d.); and the total cost (including interest and sinking fund) 1·83d. (against 1·92d.). 9,431,836 units were generated (against 8,431,114); 6,262,307 were sold for private lighting and power, and 83,700 supplied to the public lamps. There are 3,289 consumers, and the total maximum supply demanded was 4,790 kw.

In presenting the accounts, the chairman of the committee (Mr. E. HANGER) said that the figures had justified the statement in his report of 12 months ago that the electricity undertaking was becoming an increasingly valuable asset of the Corporation. An examination of the details of working expenses showed that for the last few years considerable sums had been allocated to the purchase of new plant and materials, a policy which must necessarily have the effect of strengthening the financial position of the undertaking; in addition, the gradual process of entire renewal of the old type mains in the centre of the town had been steadily proceeding, and in the year under review the whole of George-street, as well as a large number of small isolated portions of the mains, had been so renewed. In spite of the general reduction in sales, which had been going on all over the country, due to the advent of metal filament lamps, the income of the department had increased by over £500. The increased revenue from power supply was over £2,500, and experience in other towns had shown that it would be largely due to increased sales in that direction that they must look for developments of the undertaking in the future. Commendable improvements in working costs have been made by the engineer (Mr. H. Bell) and his staff, and they were for the first time able to record the figure of ¾d. as the works cost, and under 1d. per unit sold for the total cost. During the year they had put down no additional generating plant, as that already installed

Digitized by Google

had proved adequate for present requirements, largely due to the increased use of more economical lamps, but there was abundant evidence to show that at no distant date they should have to be prepared to instal extensive additions.

Islington (London).—The total income of the Electricity department for the year ended March was £55,135 (against £55,615), including £37,658 from the sale of current for private lighting (£36,391) and £12,100 for public lighting (£15,734).

Total expenses were £27,598 (against £29,862), and included £14,944 for cost of generation (£16,694), leaving a gross profit of £25,537 (£25,753). Interest on loans and income tax absorbed £13,791, repayment of loans £8,647, and after allowing for bad debts, &c., the balance (£3,027) was carried to reserve. The works costs per unit sold were 0·77d. (0·9d.), and the total costs (including interest and sinking fund) 2·12d. (2·31d.) 5,301,899 units were sold (4,974,901); there are 2,130 consumers (1895), and the total connections in 30 watt lamps are equal to 213,688 (200,430). There are 615 street arc lamps (610), and the load factor was 15·67 (15·80) per cent. The net capital expended during the year was £11,782, making a total of £488,069. 12s. 2d.

The report of the engineer and manager (Mr. A. Gay) states that every item of the costs per unit sold has been reduced, with the exception of repairs and maintenance, and that the works costs (0·77d. per unit) are below the average for the whole of the Municipal undertakings in London. The reduction in the price of coal was responsible for a saving of £1,291, while other economies represented £1,431. About 2,500 tons less of coal were consumed, although 327,000 more units were generated. The increase in the number of units sold was due to the demand for power. During the year 53 motors and 25 radiators were connected, which, together with the additional lamps connected, represented an increase of 13,258 30 watt lamps.

Leigh (Lancs.)—At their last meeting the Town Council adopted the report and accounts of the electricity department for the year ended March, which state that the capital expenditure is £46,421 (increase £673).

Revenue was £7,890 (against £7,767 in previous year), total working costs £4,629 (against £4,294) and gross profit £3,261 (£3,473). After providing for interest £1,237 (£1,273), sinking fund contribution £1,367 (£1,326) and £545 for depreciation of motors and purchase of plant out of revenue (against £514), there was a net profit of £112 (£360). The maximum load was 471 kw. (440 kw.) and the load factor 19·5 (20) per cent. Average price obtained for current was 2·10d. (2·14d.) Units sold for lighting were 239,782 and for power 569,493, total 809,275 (increase 40,163). The revenue included £388 (against £387) rentals of motors, &c., on consumers' premises and £426 (£493) from sales of lamps, fittings, &c. The decrease in net profit is attributed to abnormal charges for repairs and maintenance. There are 432 (399) consumers connected, with 20,919 (20,363) equivalent 8 c.p. lamps, and the number of motors connected is 174 (= 1,085 H.P.), the same as at March, 1909.

Rotherham.—The total revenue of the Electricity department for the year ended March 31 was £14,824, including £14,530 from sale of current (303,362 units for lighting, 465,553 for power and 1,209,097 for traction.)

Working expenses were £7,906 and gross profit £6,918. After paying interest, sinking fund, &c., there was a net profit of £2,922, of which £2,000 was voted to relief of rates, and the balance placed to renewal fund. Capital expended is £57,663, an increase of £2,869.

Traffic receipts of the tramways department were £31,059, and total receipts £31,278. Expenses came to £22,363, and gross profit was £8,915. After allowing for the contributions from electric lighting department for loan charges and renewals fund, &c., and paying sinking fund, interest on mortgage debt, &c., there was a balance of £3,807. 19s. 9d. 6,341,671 passengers were carried and 666,800 car-miles run. The capital expended is £151,919. 11s., an increase of £15,971. 10s. 9d.

Stalybridge, Hyde, &c., Tramways and Electricity Board.—The accounts for the year ended March 31 have been issued.

Traffic revenue of the tramways department was £37,922 (including £280 from parcels). Total income was £38,055. Working expenses were £28,962, leaving a gross profit of £9,093. Interest came to £8,513, bank charges to £467, and sinking fund to £6,562, making the net deficit £6,449. 10,190,944 passengers were carried and 1,295,018 car-miles run.

The income of the electricity supply department was £30,103, including £29,842 from sale of electric current for lighting and traction. After paying expenses the balance was £13,348. Interest came to £7,457, bank charges to £409 and sinking fund to £5,951, leaving a deficit of £469. 10,023,140 units were sold to private consumers, 2,055,012 were supplied to the tramways department and 4,000 for public lighting. The total capital expended on the electricity department is £258,287 and on the tramways £279,475.

Wolverhampton.—The total income of the municipal tramways worked on the Lorain surface contact system) for the year ended March 31 was £45,499. 17s. 9d., and included £44,757 for traffic receipts.

Working expenses were £27,584 and the gross profit £17,915. After paying interest and sinking fund there was a net profit of £5,667. Gross capital expenditure is £277,195. Passengers carried were 9,670,657 and car-miles run 1,030,720. The number of units of current used per car-mile was 1·408, and the percentage of working expenses to total revenue was 60·6. Of the net profit £4,891 was placed to reserve and renewals fund, which now amounts to £32,395.

TRADE NOTES AND NOTICES.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.—The 1910 Edition of the Big Blue Book is NOW READY, price 15s., post free in the United Kingdom, 15s. 9d. The volume brings a great mass of very valuable statistical and technical data quite up to date, and the Directorial Division has been thoroughly revised and amplified up to February 16th.

All branches of Electrical Engineering and Industry are fully treated, and Electro-Financial matters receive every attention in the new volume, which aggregates more than 2,000 pages. The Directory Division is complete and thoroughly accurate, and has been completely revised. The Big Blue Book contains more names of live electrical firms and persons than any other Directory published, and this notwithstanding that all mere lists of members of Societies and Institutions (so easily and cheaply available) are excluded, as unreliable and of little value for Manufacturers' and Dealers' purposes. The full set of valuable Statistical and Engineering Tables, &c., have been very carefully revised and extended, and are now issued in a handy form. These are included in the 1910 Big Blue Book, making it the most complete work of the kind ever published.

TENDERS INVITED.

St. Pancras (London) Borough Council invite tenders for supplying a marine type water-tube boiler, fitted with induced draught. Copies of specification, &c., from the electricity department offices, 57, Pratt-street, Camden Town, N.W. Tenders to the town clerk (Mr. C. H. F. Barrett), Town Hall, Pancras-road, N.W., by 10 a.m. of Monday July 11. See also an advertisement.

London County Council invite tenders for wiring and fitting for electric light of the second portion of the central car repair depot Woolwich-road, and the supply and delivery of l.t. cables, cable boxes, &c., at the central depot. Specifications, forms, &c., from the Clerk of the Council, Mr. G. L. Gomme, County Hall, Spring Gardens, S.W. No tender received after 11 a.m. of July 12, will be considered. See also an advertisement.

London County Council also require tenders by 11 a.m. July 6 for electric wiring at St. Mark's-road and Haverstock Hill schools. Specifications from the Chief Engineer, Spring-gardens, S.W.

London County Council also require tenders by 11 a.m. July 5 for supply of 250 electric tramcar bodies and 250 electrical equipments for conduit and overhead systems. Specifications from the Clerk.

Tenders are invited by July 6 for the supply of cordless switchboards to the Postmaster-General's Department in South Australia. Tender forms and specification may be obtained at the Commonwealth Offices, 72, Victoria-street, London, S.W. See also an advertisement.

Fleetwood Council require tenders by noon July 15 for supply of a 300 kw. steam dynamo, a.l.-t. main switchboard and a 10-ton overhead travelling crane. Specifications, &c., from the Electrical Engineer, Albert-square, Fleetwood.

Newport (Mon.) Corporation want tenders by first post July 8 for a wooden water-cooling tower (capacity 200,000 gallons per hour) for the electricity department. Particulars from the Borough Electrical Engineer.

West Ham Education committee want tenders by 6 p.m. July 18 for electric lighting installation work at West Silvertown school. Specifications, &c., from Mr. Wm. Jacques, 2, Fen-court, E.C.

Swansea Harbour Trustees require tenders by 10 a.m. July 15 for three 2-ton electric transporters and overhead travelling cranes. Forms of tender, &c., from the Clerk.

Salford Corporation require tenders by noon July 18 for a bore-hole pumping plant for their electricity works, Pendleton. Particulars from the Borough Electrical Engineer.

Hornsey Council want tenders by 10 a.m. July 9 for the electric wiring and fitting of Stroud Green school. Specification, &c., from the Borough Electrical Engineer.

Rotherham Corporation require tenders by July 9 for 12 months' supply of cable and electricity meters. Further particulars from Borough Electrical Engineer.

Tenders are wanted by July 11 for wiring and fitting of Bridlington Grammar School on the O.S. system. Specification from the Electricity Works.

Digitized by Google

BELFAST Guardians want tenders by noon July 5 for an electrical installation for the Abbey auxiliary workhouse. Specification, &c., from the Clerk.

WELLINGTON (N.Z.) Corporation want tenders by 4 p.m. June 30 for supply of three electrically driven multi-stage turbine pumps. Some particulars obtainable at 73, Basinghall-street, London, E.C.

The NEW SOUTH WALES State Railways Department require tenders by July 18 for supply and erection of three 5-ton overhead electric cranes and one 1½-ton and one 1-ton electric travelling crabs. Particulars from the Electrical Engineer, Sydney, N.S.W.

Tenders are invited for the supply to the Postmaster-General's Department, NEW SOUTH WALES, of one dust extractor, electrically driven, to work on a 24-volt d.c. circuit. Tender forms, &c., from the Commonwealth Offices, 72, Victoria-street, London, S.W.

Tenders are invited up to Aug. 2 for the supply and delivery of 1,820 private letter box fronts to the Postmaster-General's Department in the States of VICTORIA, QUEENSLAND, SOUTH AUSTRALIA and WESTERN AUSTRALIA. Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W.

Tenders are invited up to July 27 for supply of a pneumatic tube service to the Postmaster-General's Department at ADELAIDE (S. Australia). Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W.

Tenders are invited up to July 19 for supply and delivery of 4,200 telephone sets (as per schedule No. 231) to the Postmaster-General's Department in VICTORIA. Tender forms and specifications from the Commonwealth Office, 72, Victoria-street, London, S.W.

The Turkish Ministry of Commerce and Public Works want tenders by Oct. 28 (Nov. 10) for a concession for the construction and working of electric tramways in CONSTANTINOPLE and suburbs. A deposit of £13,500 (sterling) is required with each tender. Local representation is essential. Copy of specification (in French) may be seen at 73, Basinghall-street, London, E.C.

The Société Nationale des Chemins de fer Vicinaux, BRUSSELS, want tenders by July 20 for underground cables, and by July 27 for the equipment of a transformer station.

The Ministerio de Fomento, MADRID, will receive tenders until July 30 for the construction of an electric (or steam) strategic railway from Requena to Alcaráz, via Casas Ibáñez and Albacete. The contract is open to Spanish firms only.

The Ministerio de Obras Publicas, SANTIAGO (Chili), will receive tenders until July 15 for the substitution of electric for steam traction on the first section of the Chilian State Railways—from Valparaiso to Santiago and Los Andes.

SHANGHAI Municipal Council invite tenders for supply and delivery (c.i.f. Shanghai) of two 940 k.v.a. two to three-phase step-up transformers, e.h.t. switchgear, e.h.t. underground mains and feeder pillars. Specifications from Messrs. Preece & Cardew, 8, Queen Anne's-gate, Westminster, S.W., to whom tenders before noon July 5.

Tenders will be received at the State Railway Offices, VILLACH, Austria, until July 15 for the construction of two electrically driven locomotive turntables.

TENDERS RECEIVED AND ACCEPTED.

Erith Council received seven tenders for a 750 kw. three-phase turbo-alternator, surface condenser, air and circulating pumps and pipework (from the General Electric Co., the British Westinghouse Co., Willans & Robinson, the British Thomson-Houston Co., C. A. Parsons & Co., Jas. Howden & Co. and Fraser & Chalmers); and 12 tenders for a Lancashire boiler, mechanical stokers, superheater and pipework (Babcock & Wilcox, W. Arnott & Co., A. Brown & Co., E. Danks & Co., Yates & Thom, Hawksley, Wild & Co., Ruston, Proctor & Co., Spurr, Inman & Co., Fraser & Chalmers, Clarke, Chapman & Co., John Thompson & Galloways (Ltd.). Consideration of the tenders has been reserved.

London County Council have accepted the following tenders:—

Pinching & Walton (lowest tender) for wiring and fitting Hammersmith Bridge for electric lighting at £230. 19s. 6d. (Three tenders received; highest £328. Chief engineer's estimate £200.)

G. A. Gorden & Sons for enamelled iron advertisement plates for use in connection with the tramways, at 8¾d., 9d., 9¼d. and 10d. a foot super for two, three, four and five colours respectively, and the Patent Enamel Co. (Ltd.) for finger plates at 6d. each for either two, three, four or five colours.

For the electric lighting of the Stewart Institution, Chapelizod, Dublin, the following tenders were received:—

T. E. Brunker (*accepted*)	£1,537	J. C. Meldon	£1,569
Wm. Coates & Son	1,742	Estate Engineering Co	1,530
C. J. Cummins	1,702	Fletcher & Phillipson	1,520
Macredy, Eaton & Davidson	1,670	Maguire & Satchell	1,510
Egan & Co.	1,579		

Bolton Electricity committee have accepted the following tenders for annual stores:—

T. Moscrop & Co., crank chamber oil, &c.; Wareing & Co., light machine oil, paraffin oil, soda, white lead and soad ash; Joshua Orrell & Co., paint, boiled oil and solidified oil; Geo. Reason, cotton waste; and Messrs. Townson & Sons, timber.

The L.&.N.-W. Rly. Co. have accepted the tender of Wm. Geipel & Co. for the supply of Henrion arc lamp carbons during the year ending June 30, 1911, for the whole of the company's requirements, the total annual consumption amounting to 1,373,000 carbons. This is a renewal of last year's contract.

Belfast Harbour Board have accepted the tender of Hind Bros. & Co. for 22 tubular arc light masts at £7. 15s. 6d. each, less 2½ per cent., in place of the tender of Jas. Allan (Sen.) & Sons, which was withdrawn.

Southend Council have accepted the tender of Smith & Sons for an electric crane at £487; and that of the Brush Co. for lengthening a single-truck car at £200.

We are informed that Londonderry Corporation and the N.S.W. Govt. Railways Dept. have placed orders with Willans & Robinson for turbo-alternators,

Luton Council have accepted the tender of Hughes & Lancaster for a motor-driven air compressor at £375. 10s.

Salford Guardians have accepted the tender of Lightfoot Bros. for wiring the operating theatre at the Infirmary for £52. 10s.

The tender of Walter Scott (Ltd.) has been accepted by Huddersfield Corporation for supply of tram rails for the Linthwaite track.

Commonwealth Tenders.—The Works and Buildings Department (Adelaide) have accepted the tender of Unbehaun & Johnstone for supply and erection of an electric goods elevator at the Government Printing Office at £238. 10s.

The tender of Siemens Bros. Dynamo Works for 1,640 iron telegraph poles at £5,119, has been recommended for acceptance by the Postmaster-General's Department, Melbourne.

The Victorian Railway Department has placed a two years' contract with the Welsbach Light Co. of Australasia for supply of metal filament lamps.

BUSINESS NOTICES.

The telegraphic address of W. T. Henley's Telegraph Works Co. (Ltd.) is now "Henletel London." The word "Henletel" is also registered for use in connection with the company's branches at Glasgow, Newcastle, Manchester and Birmingham.

Hy. Taffs and Chas. F. Toft (trading as H. Taffs & Co.), electrical engineers, 40, Brazenose-street, Manchester, have dissolved partnership. Debts by Mr. Taffs.

American Electricity Supply, Tramway and Railway Undertakings.—From the McGraw Publishing Co., 239, West 39th-street, New York we have received copies of the Lighting and Power edition, and of the Electric Railway edition of the McGraw Electrical Directory for 1910.

The Lighting and Power edition is divided into three sections, (1) a central station list; (2) dealers and contractors' section, and (3) buyers' manual section, which includes a classified list of manufacturers, a dictionary for buyers, and a literary section. In the central station list are included particulars of the various electric lighting and power plants in the whole of the United States, Mexico and Canada. The information given includes the names of the chief officials (president, manager and engineer), voltage of supply, frequency, charges for supply, street lighting statistics, &c., there are over 5,550 central stations in the U.S.A., of which particulars are given, 425 in Canada, 71 in Mexico and 9 in the West Indies and the Republic of Panama, a total of 6,055 stations. The number of plants giving d.c. supply is 1,650, while there are 4,414 a.c. plants. The present edition (April, 1910) contains 210 new entries.

The contractors' section is also a very complete one, and the whole of the information seems to have been carefully compiled and edited. The subscription price is $10 per year.

The Electric Railway edition gives a good list of manufacturers of electric railway plant and apparatus, and this is followed by statistics and data relating to the electric railways in the United States, Canada and Mexico. The information includes the names of the chief officials, power station equipments, length and gauge of line, number of cars, &c. There is also an alphabetical list of street railway officials, together with particulars of the National and State Railroad Commissioners, street and interurban railway associations, &c. The subscription price is $5 per year.

Each edition is published semi-annually, and each book has a good index making it easy of reference.

CATALOGUES, &c.

TANTALUM LAMPS.—Messrs. Siemens Bros. Dynamo Works send us a leaflet giving full particulars of the reduced prices of tantalum lamps. All voltages, candle-powers and sizes of bulb sare dealt with.

ELLISON STARTERS.—We have received from Mr. Geo. Ellison, of Birmingham, a pamphlet giving details of no-voltage and overload release starters for slip-ring or squirrel cage a.c. motors made by him. These starters can either be totally enclosed, for use in mills and other similar places, or can be made in the usual open fashion. Particulars, prices and capacities are given.

D.P. BATTERY INSTALLATION.—The D.P. Battery Co. have ready a pamphlet describing an installation consisting of a battery and booster recently erected by them at Messrs. Rowntree's works at York. The installation possesses some interesting features and we hope to return to it again.

B.T.-H. CONTINUOUS-CURRENT MOTORS AND GENERATORS.—We have received from the B.T.-H. Co. a list illustrating and describing a new design of B.T.-H. continuous-current motor and generator. These machines can be fitted with various styles of covers and be thus rendered flame, dust or moisture-proof, whilst they can also be protected so as to work satisfactorily in all kinds of inconvenient positions.

ELLIOTT INSTRUMENTS.—Messrs. Elliott Bros. have issued a number of pamphlets illustrating and describing some of the instruments made by them. These include switchboard instruments, current and potential transformers, portable transformers, photometers, as well as galvanometers and keys and switches of various kinds.

O.S. ELECTRIC WIRING SYSTEM.—A pamphlet sent out by Messrs. Siemens Bros. & Co. deals with this system, and consists of a more or less popular description of this method of wiring, which includes illustrations of actual surface Stannos runs, as well as a series of pictures of all sorts of buildings which have been wired with Stannos. Another pamphlet shows Stannos wiring applied to Cambridge Colleges and describes some of the recent installations that have been made in these places.

THERMO-ELECTRICAL PYROMETERS.—A catalogue just issued by Messrs. Siemens Bros. & Co. contains various new features in connection with their thermo-electrical pyrometers. This supersedes the catalogue issued in October, 1907.

"CASTLE" MOTORS AND DYNAMOS.—Messrs. J. H. Holmes & Co.'s new catalogue gives particulars of their continuous-current motors and dynamos.

OIL GOODS.—Messrs. Ragosine & Co. are issuing a catalogue which gives details of various oil goods and varnishes made by them.

EDISWAN BELLS AND TELEPHONES.—The Edison & Swan Company have ready catalogues dealing with their makes of bells and telephones.

BANKRUPTCIES, LIQUIDATIONS, &c.

A first and final dividend of 20s. in the £ will be payable on July 4 at 8, Frederick's-place, Old Jewry, London, E.C., in the liquidation of the Phosphor Bronze Co. (Ltd.)

In the voluntary liquidation of Prockter & Kenyon (Ltd.) a meeting of creditors takes place on July 5 at Mr. T. Walton's, 36, Spring Gardens, Manchester.

A meeting to receive an account of the winding-up of Mackey's Electric Lamp Co. (Ltd.) (in liq.) will be held at 174-5, Aldersgate-street, London, E.C., on Aug. 3.

A meeting to receive an account of the winding-up of the Bradford Electrical Engineering Co. (Ltd.) will be held at Mr. J. H. Haley's, Tyrrel-street, Bradford, on July 25.

A meeting to receive an account of the winding-up of the Electric Sterilizing, Carbonizing and Stripping Co. (Ltd.), will be held at Prudential-buildings, Market-place, Dewsbury, on July 27.

BOOKS RECEIVED.

(Copies of the undermentioned works can be had from *The Electrician* office, post free, on receipt of published price, adding 3d. for books published under 2s., and 5 per cent. for books published nett. Add 10 per cent. for abroad or for foreign books.)

"Einführung in die Technische Elektrochemie." Vol. I. "Elektrothermie." Edited by Dr. Paul Askenasy. (Brunswick: F. Vieweg und Sohn.) M.10.

"Die Europäischen Fernsprechgebührentarife." By Dr. Erwin Günther. (Jena: Gustav Fischer.) M.6.

"Messungen an Maschinen und Motorem fur Ein-und Mehrphasen-Wechselströme." By Fritz Hoppe. Part IX. of "Sammlung elektrotechnischer Lehrhefte." (Leipzig: J. A. Barth.) M.5.80.

"Prinnip und Wirkungsweise der technischen Messinstrumente für Wechselstrom." By Fritz Hoppe. Part IV. of "Sammlung elektrotechnischer Lehrhefte." (Leipzig: J. A. Barth.) M.4.

COMPANIES' MEETINGS AND REPORTS.

Aron Electricity Meter (Ltd.)

The thirteenth ordinary general meeting of the company was held on Friday last, under the presidency of Mr. H. HIRST, M.I.E.E., chairman of the company.

The SECRETARY (Mr. M. Aron, F.C.I.S.) read the notice convening the meeting and the report of the auditors.

The CHAIRMAN then said: Gentlemen, it is again our pleasure to submit for your approval the report of a year's trading. The similarity of the figures in the balance-sheets of 1909 and 1910 shows that our business has attained a pleasant stability. Our profits have risen in this year's accounts to the satisfactory total of £35,630, or £1,330 more than last year, which was, up to that time, our record year. The other items on the profit and loss account are within a per cent. or two the same as last year. We have written off £400 more depreciation, not because our plant is in any worse condition, but in an industrial business like ours, which is constantly in process of evolution, one likes to use some of the profit of good years for writing down certain capital items. Maintenance of patents is a few hundred pounds less, and so, naturally, is debenture interest, for our debenture debt decreases every year by the repayment of about £5,000. As regards the balance-sheet, only two figures call for comment. We have added to our leasehold land, buildings, machinery and tools £9,279. This figure is largely composed of additional land and buildings rendered necessary by the increase of our business. We have less cash to the extent of £15,000, if I include in this item loans at short notice. This is accounted for by the greater trading outstandings, which are £58,000 this year, against £40,000 last year, and also to some extent by the extensions of the taximeter business. The taximeter business particularly is at present absorbing money. These instruments, as I have previously stated, are not sold outright, but are hired out, mostly for periods of about five years. We have received very satisfactory contracts in London, Brussels and Vienna for hiring out taximeters, and while we have to manufacture and instal every instrument, the cost of both manufacture and installation has to be defrayed at present from our liquid assets. Payment, however, is received only in monthly or quarterly instalments, and it follows that the outgoings, so far as capital expenditure is concerned, are still greater than the incomings, and this state of affairs is likely to continue for some time if we are successful in obtaining more orders. The profits we have shown in this year's accounts have been made entirely by our old-established meter and clock business. For the safety of the company, the directors have so far used all the income received from taximeters against manufacturing and installation expenses.

It is a matter of great satisfaction to the board, and particularly to Prof. Aron as managing director and to myself as chairman, that we are able this year to recommend the distribution of a dividend which will clear off the last of the arrears due to preference shareholders (cheers.) Our conservative policy, which necessitated in years gone by the accumulation of these arrears, has been vindicated, not only by our ability to pay them back now, but also by having established a business which shows a greater turnover and profit than at any time during its existence. We are firmly planted in nearly every European country, and we have found a particularly useful outlet for our manufactures in the constantly growing and prosperous power companies on the Continent. The average yield per meter is less than in former years, but we have made up for this by selling a very much larger number of meters, and, I may add, by manufacturing more cheaply. I can only add that I sincerely hope—and there is great reason for that hope—that the ordinary shareholders will in the near future be rewarded for their great patience (cheers). Before putting the motion for the adoption of the report and accounts to the vote, I wish to express my pleasure that Prof. Aron is able to be present at this year's meeting, and I am anxious to take this opportunity of thanking him for the hard and great work which he has given unstintingly to our company, and which has been the mainspring of our success (hear, hear). He has been loyally backed up by our excellent staff, whom he has placed in charge of our various undertakings in the different countries, and their efficiency and loyal and strenuous work are greatly due to his master mind which has controlled them. I now move the adoption of the report and accounts.

Sir JAMES PENDER, Bart., seconded the motion, which was carried unanimously.

A resolution approving the payment of the dividend of 9 per cent. on the preference shares was then approved.

Mr. ROGER W. WALLACE, K.C., moved the re-election of the retiring directors, Mr. H. Hirst and Sir James Pender, Bart., and expressed his pleasure in moving the resolution. He said their chairman was a gentleman who was eminently suitable for the position. It was extremely desirable that the head of such a company should be someone in a position such as Mr. Hirst so successfully occupied. With respect to Sir James Pender, he was well known in connection with electrical matters, as he was a director of many other electrical concerns. The qualifications of both gentlemen were, therefore, exceptional.

Mr. HARRY KAHN seconded the motion, and said they could not but realise the tremendous amount of work their chairman had done for the company.

The motion was carried unanimously.

The retiring auditors, Messrs. Price, Waterhouse & Co., were then reappointed, and a cordial vote of thanks to the chairman and to Prof. Aron terminated the proceedings.

Digitized by Google

BOMBAY ELECTRIC SUPPLY & TRAMWAYS CO. (LTD.)—The report for 1909 states that the total revenue for the year (including amount represented by sale of current to the tramways) was £197,827, an increase of £19,972. Expenditure was £115,132, an increase of £4,343. The net receipts were £82,695, compared with £67,066. With amount brought forward (£9,385), the available total is £61,550. Deducting preference dividend and transferring £6,000 to sinking fund for capital redemption the directors propose to place £15,000 to depreciation, leaving to be carried forward £4,567. The directors have been in negotiation with the Municipal Corporation with a view to an increase in the rates charged on the tramways for long distance fares, and the Corporation have sanctioned for two years the alterations applied for, as from April 1, 1910. The directors have decided to substitute for the maximum demand system of charging for electricity flat rate charges. The work of erecting the new Kasara generating station, which is to replace the existing generating station at Wari Bunder, is being actively prosecuted. Capital expenditure during the year was £41,136.

BRITISH ALUMINIUM CO. (LTD.)—At the statutory meeting on Wednesday, Mr. A. W. Tait said that the new company was incorporated on April 15, and the whole of the shares to be issued under the scheme of reconstruction had been allotted. The issue of £800,000 5 per cent. prior lien debenture stock, which was also a part of the scheme, was successfully accomplished. The new company would therefore be in possession of funds to the extent of £974,433 when the calls upon the prior lien debentures and the shares which had been allotted were fully received. The scheme of reconstruction had been successfully carried through. The liabilities of the old company had all been discharged, and the repayment of loans in connection with the Martigny-Osnieres Railway had also been effected. The new company was in possession of funds to complete the Loch Leven works, to provide for further capital expenditure, and to have a sufficient sum for additional working capital.

CHILI TELEPHONE CO. (LTD.)—The report of the directors for the year ended March 31 last states that the aggregate number of subscribers at all centres at that date was 8,818, compared with 8,011 at the beginning, a gain of 807. Gross revenue in Chili from all sources was $1,851,689, against $1,720,716 in 1908-9, an increase of $130,973. Expenditure in Chili was $926,387, against $824,082, an increase of $102,305. Net income in Chili was $925,301, against $896,633, an increase of $28,668. The average rate of exchange for the year was 10·49d., compared with 10·09d., an increase on the year of 0·40d. Converted into sterling the figures are: £40,411 for 1909-10, against £37,698, increase £2,713. The liquid assets and liabilities in Chili on March 31, 1910, were valued at 10½d., the current rate of exchange on that day, compared with 11⅛d. on the corresponding date of the previous year. The balance to credit of revenue, including £2,820 brought forward, is £41,091, of which £20,504 has been carried to reserve. An interim dividend of 3s. per share (tax free) was paid on Jan. 15, and a final dividend of 5s. per share (tax free) is now recommended, leaving £2,987 to be carried forward. The total mileage on March 31 was 15,316 miles 812 yds., an increase of 1,195 miles 228 yds. in the year.

ELECTRIC & GENERAL INVESTMENT CO. (LTD.)—The directors' report for the year ended May 31 states that the gross profit was £13,086. 19s. 6d. After deducting all general charges and interim dividend already paid on the preference shares, and providing for proportion of final dividend accrued on the preference shares to May 31, there remained £5,496. 7s. 1d. As a further reserve to meet depreciation in investment and loan securities, the directors have carried £4,296. 7s. 1d. of this amount to contingencies fund, thereby raising this fund to £75,948. 4s. 9d., leaving £1,200, which the directors recommend shall be distributed by the payment of a dividend at the rate of 6 per cent. on the capital paid up on the ordinary shares for the year. The trustee for the ordinary shares reserve fund proposes to distribute 6d. per share out of the dividends received on the trust investments, and the trustee for the founders' shares reserve fund proposes to distribute £7 per share out of the dividends received on the trust investments.

ELECTRIC TRACTION CO. OF HONGKONG (LTD.)—The report for 1909 states that the gross traffic receipts show an increase over 1908 of more than £2,500, in spite of the further decrease in the rate of exchange; and the working expenses show an increase of some £1,200. The result for the year, after providing for working expenses and payment of debenture interest, is a profit of £5,282, which, added to amount brought forward, makes £5,568. The directors consider it desirable to continue the policy of previous years by allocating £5,000 to reserve for depreciation and renewals, the balance (£568) being carried forward. The manager reports that he anticipates being able to recommend in the near future the purchase of 10 further cars to meet the growing traffic, and this will probably necessitate the purchase of additional land for a new car shed. The special valuation of the company's undertaking by Mr. J. H. Garratt has been received and amounts to £240,000. Having regard to that valuation, the board recommend that the share capital of the company be written down from 325,000 £1 shares to the same number of 5s. shares, and a resolution will be submitted to the shareholders for that purpose at an extraordinary general meeting. It is also proposed to change the company's name to the "Hongkong Tramway Co. (Ltd.)."

KALGOORLIE (W. AUSTRALIA) ELECTRIC TRAMWAYS (LTD.)—Gross receipts during 1909 amounted to £45,266, compared with £47,368 for 1908, and the net profits to £16,573, against £15,400. The cars travelled 631,242 miles, against 647,297, and carried 2,936,411 passengers, against 3,028,419 in 1908. The earnings per car-mile were 17·16d., compared with 17·53d., while expenses per car-mile were 10·29d. against 11·25d. The expenses per cent. of earnings in 1909 were 59·99, against 64·17 per cent.

MARCONI INTERNATIONAL MARINE COMMUNICATION CO (LTD.)—The report for 1909 states that the business has now reached the stage when the revenue exceeds the somewhat heavy standing expenditure necessary in such a business. The directors are confident that the business will continue to show considerable extension. The greater facilities to communicate with the shore, the continuously growing number of ships installed, together with the more general custom of communicating with and from ships at sea, should ensure rapidly increasing profits.

At the meeting on Wednesday the directors' report and accounts were adopted.

MARCONI'S WIRELESS TELEGRAPH CO. ((LTD.)—At the meeting on Tuesday the chairman (Mr. G. MARCONI) said it must be satisfactory to all interested in the company that a profit had been made during the past year, notwithstanding the absence of any practical assistance to their revenue through the misfortunes at the Glace Bay Station, which stopped their trans-Atlantic service. The profit earned, it was true, was not large, but the extension of the business was such that the directors felt warranted and had considerable satisfaction in recommending the payment of the 7 per cent. dividend on the cumulative preference shares to June 30, 1909, and they were hoping that it would not be long ere they would be able to make a further payment, paying up the cumulative dividend to the end of 1909. The work which they had in hand and in prospect, the general development of their business, together with the opening of the trans-Atlantic service, gave them good reason to expect that not only should the preference shareholders be able to look in future to the regular payment of their dividend, but that the ordinary shareholders might also look to an early reward for their patience. The future policy of the company was to open a large number of telegraph services throughout the world. In the past they had had to be satisfied with what might almost be termed the profits of a manufacturer's business; but they had always had present in their minds the immense scope of this and their associated companies in turning to account the principal value and utility of wireless telegraphy applied to long distances. They had already submitted a general scheme to the Government, and had every hope that at a not too distant date they should obtain the licences which they required. Speaking for himself it would be impossible for him to give his best attention to the technical and scientific supervision of the company's affairs so long as he was also responsible for its business management. He, therefore, endeavoured to find a person who could take hold of the business management of the company, and last winter he was fortunate enough to find a gentleman possessing the necessary ability and experience to enable him to successfully fill the position of managing director. Mr. Godfrey Isaacs was elected joint managing director last January. Both himself and his colleagues on the board had been agreeably surprised at the thorough grasp Mr. Isaacs had obtained of their business in so short a time. Speaking for himself personally, as well as for the board, he might say that they all felt that Mr. Isaacs was just the man they wanted, and was a gentleman in whose ability and integrity every member of the company could place the fullest confidence. He must say that from shortly after the time Mr. Isaacs became associated with them he had been able to attend in a much greater measure to the technical side of their work, and it was his (Mr. Marconi's) intention to shortly resign from the position of joint managing director in order that he might be able to give his best attention to the work for which he felt most adapted and in which capacity he could be of most value to the company. The directors wished to again put on record their appreciation of the work carried out by the company's staff both at home and abroad, and he himself should also like to acknowledge the assistance he had received from his co-directors.

Mr. GODFREY C. ISAACS said they were practically ready almost at a moment's notice to proceed to any part of the world and erect wireless telegraph stations in the space of a very short time. He could not give them a better instance of that than by quoting an actual fact. H.M. Government placed an order with the company on Feb. 12 last to enable them to communicate across the Gulf of Aden. Within six days the engineers were on their way; the necessary material and drawings followed almost immediately, and by May 12 communication was established by wireless telegraphy and the work completed.

In reply to questions by Mr. Fisher, the chairman said that the greater portion of the £15,000 paid by the Post Office for the purchase of ship-shore stations went to the International Co., which was one of their subsidiary companies, and to whom these stations belonged. The transfer of these stations to the Post Office was very good business for them. Certainly the amount of money paid might have been greater, but still the chief source of revenue from the ship-shore point of view should be the ships. The land stations were necessary in order that the ships should have points with which they could communicate, but he thought it very desirable that those land stations should be worked by the Government. He must say that they were worked very well by the Government, and that their revenue had in no way suffered in consequence.

The resolution was carried unanimously.

Mr. Godfrey C. Isaacs and Mr. Alfonso Marconi were elected directors, and the re-election of Major S. Flood Page, Mr. Henry S. Saunders and Mr. Samuel Geoghegan was also agreed to.

Mr. J. HENNIKER-HEATON proposed a hearty vote of thanks to Mr. Marconi, which was seconded by the Hon. GEORGE MANNERS, and carried unanimously.

PERTH (W. AUSTRALIA) ELECTRIC TRAMWAYS (LTD.)—The gross receipts during 1909 amounted to £74,649. 0s. 5d., compared with £73,338. 12s. for 1909; and the profit was £30,161. 5s. 2d. against

Digitized by Google

£28,720. 12s. 2d. Traffic receipts show an increase over 1907 and 1908, and, with the exception of 1906, are the highest since the inception of the company. The sum at credit of profit and loss account is £12,456. 5s. 2d. Adding £1,099. 15s. 11d. brought forward the total is £13,556. 1s. 1d., from which £6,000, preference dividend has been paid. The balance (£7,556. 1s. 1d.) is sufficient for a distribution of 5 per cent. to the ordinary shareholders, but the directors are unable to recommend so large a dividend in view of the repayment of the loan of £4,000 for further rolling stock and construction work on extensions. They therefore recommend that £4,000 be placed to reserve for extensions, and that a dividend on the ordinary shares of 2½ per cent. be paid, leaving £1,056. 1s. 1d. to be carried forward.

RIO DE JANEIRO TRAMWAY, LIGHT & POWER CO. (LTD.)—At the meeting last week it was reported that during 1909 the work of construction was largely confined to the extension in the Federal District of the light and power distribution systems to meet the growing demands and with a view to developing the system, and to the reconstruction of the tramways for electric operation. Additional duct lines, aggregating 225,950 lineal feet and five large transformer vaults were installed, giving a total of 1,598,945 lineal feet of ducts, 79 transformer vaults and 309 manholes completed up to Dec. 31. A large amount of underground and overhead high-tension feeders have been installed including an independent line of cable for supplying power to the Federal Government for lighting and operating the docks, for which at the present time there have been installed transformers of 810 kw. capacity. In the reconstruction of the mule tramway lines there have been laid during the year 73·34 miles, including 3·68 miles of the Villa Isabel system. During the year 132 passenger cars were put into service. The Corcovado rack railway has been electrically equipped with three-phase alternating current locomotives of the Maschinenfabrik Oerlikon. This line has now been put into electrical operation.

With a view to improving the telephone service and to meet future development 52,292 ft. of overhead and underground cables have been installed. A new sub-station has been commenced on Rua General Canabaar to serve the Sao Christovao and Villa Isabel districts. When these additions are completed the Company will possess three stations with a total capacity of 8,700 lines.

The business of the light and power department has grown in a satisfactory manner, with the result that on Dec. 31, the company had contracts for supply of 25,719 H.P. against 15,619 H.P. in 1908. The lighting business has also increased at a rapid rate, there being connected 90,204 incandescent lamps (against 40,179), 2,177 arc lamps (1,882) and 1,094 electric fans (691).

The business of the telephone department has been increased during the year by 572 subscribers, there being now connected 3,991 subscribers, against 3,419 in 1908. The net revenue from operation, after deduction of operating expenses, maintenance, taxes and other expenses in Rio de Janeiro, was $3,438,494·78, from which must be deducted the fixed and other charges of the subsidiary companies and the fixed charges and interest of the company ($2,288,887·29), leaving a net surplus of $1,149,607·49. A first dividend of 1 per cent. ($311,908·54) was paid on Nov. 1 last, leaving $837,698·95, which being added to the surplus in 1908 of $870,236·66, leaves $1,707,935·61.

TUBES (LTD.)—At the meeting on Friday the Chairman (Mr. A Chamberlain) said the net profit after providing for debenture interest, depreciation and all expenses, was £5,168, to which was added £6,123 brought forward. A dividend of 9d. per share (less tax) was declared, and £7,760 carried forward. The Chairman referred to the hot rolling invention and said it had proved a continued success. When the third plant was completed they would have everything there was room for at the Climax factory. In addition to its value for making steel tubes they found it would be equally valuable for copper and brass solid drawn tubes, and they proposed to make the alterations necessary in the machinery to adopt it to the solid drawn brass trade. They had provided a further safeguard for their business in a new and very successful adjunct, in the conduit department. The company had been in that trade two years, and it had proved a real live business. In addition, they had undertaken the business of advertising sign makers. They got hold of an invention which they satisfied themselves was of great value. It was of such a nature that they could replace existing signs, the cost of installing the new ones being paid for by the saving in electric current in the course of six or nine months. By that invention they were able to give a greater amount of light and greater prominence to a sign than before.

WESTERN UNION TELEGRAPH CO.—The report of this company for the quarter ended June 30 states that there was a surplus at Dec. 31, 1909, of $18,584,497.13, and net revenues in the quarter ended March 31, 1910, were $1,794,998.55. Dividend of ¾ per cent., paid April 15, 1910, required $747,711 and interest on bonded debt $433,062.50, leaving a surplus on March 31, 1910, of $19,198,722.18. The net revenues of the quarter ended June 30, based upon nearly completed returns for April, partial returns for May and estimating the business for June, are about $1,950,000, less interest on bonded debt $433,062.50, and after deducting for a dividend of ¾ per cent., about $747,750, there will be a surplus of $19,967,909.68. A dividend of ¾ per cent. is declared payable on July 15.

CUBAN TELEPHONE CO.—A statement is being issued by the London advisory board of the Havana Telephone Co. to the effect that the July interest on the bonds of the Cuban Telephone Co. will be paid by Messrs. Chaplin, Milne, Grenfell & Co. on July 1. The difficulties which have delayed the completion of the recent bond issue of the Cuban Co, have been adjusted, and the issue is now being proceeded with.

NEW COMPANIES, MORTGAGES AND CHARGES AND RECEIVERSHIP.

NEW COMPANIES.

CLOUGH, SMITH & CO. (LTD.) (110,192.)—Reg. June 15, capital £3,000 in 2,990 preference shares of £1 each and 200 ordinary shares of 1s. each, to carry on the business of builders, contractors for and constructors of public works, railways, tramways, &c. Private company. First directors, N. C. Clough and S. G. Smith.

HELSBY WIRELESS TELEGRAPH CO. (LTD.) (110,324.)—Reg. June 22, capital £50,000 in £1 shares, to carry on the business of manufacturers of telegraphic, telephone and electrical instruments and apparatus, &c., to acquire certain patents and inventions relating to wireless telegraphy and telephony, and to adopt an agreement with the Telegraph & Telephone Instruments (Ltd.). First directors, Lieut.-Col. J. Bernard and Capt. C. M. Gonne. Reg. offices, 25, Victoria-street, Westminster, S.W.

NEW ELECTRICITY CO. OF MACCLESFIELD (LTD) (110,388.)—Reg. June 25, capital £5,000 in £1 shares, to carry on the business of an electric light and power company in all its branches. The subscribers are Messrs. W. B. Esson, J. Macgregor, D. Willock, A. W. Money, J. G. Lorrain, W. T. Batho and G. J. Davis.

RIO DE JANEIRO SUBURBAN TRAMWAYS (LTD.) (110,272.)—Reg. June 18, capital £1,000 in £1 shares, to take over concessions granted or to be granted for the construction of tramways and light railways in or near Rio de Janeiro. First directors, S. Ablin, A. Ewens, H. H. Bartlett, G. M. Robertson, C. Piper, E. Sparie and Miss M. G. Smily (provisional directors). Reg. office, 7 and 8, Poultry, London, E.C.

WELDINGS (LTD.) (110,316.)—Reg. June 21, capital £1,500 in £1 shares, to carry on the business of electrical, mechanical and civil engineers and contractors, welders, manufacturers of electrical and other machinery and accessories, &c., and to adopt an agreement with W. NOTES.

L.B. & S.C. Electrification.

WE referred last week to the forthcoming notification by the directors of the L.B. & S.C. Railway of their decision to proceed with the electrification of their line to the Crystal Palace, and we indicated that this decision had been made to embrace the routes to the Palace both from Victoria and from London Bridge. A journey this week on the Brighton line shows that not only has this decision been come to by the directors, but that the work is in active progress. A large number of foundations have already been put down, and it is fairly obvious that the electrified line will be ready for running next summer. This is good news, not only for the Crystal Palace Co., but for the public. We may say that there are indications that the electrified line will be extended to Norwood Junction, and those who know the Brighton line will understand what connection at this point means.

FROM incidental inquiries we have made we consider ourselves in a position to state that the electrical working of the suburban service of the Brighton Railway has been more than a success—it has proved a revelation. We believe when the figures are published it will be found that the energy consumption is very much below the estimate; that there has been no hitch of any kind whatever to disturb the regular flow of traffic; that the effect upon the revenue of the Company has been extraordinary; that, in fact, everything claimed by electrification experts as likely to follow the experiment has occurred, and that every estimate of good results has been largely exceeded. We venture to prophesy that the time is not far distant when the directors of the Brighton line will take into serious consideration the question of extending the electrification over the whole of their system. If we are right, as we think we are, it is not out of place to congratulate heartily the Company's consulting engineer, Mr. PHILIP DAWSON, and all the contractors, on the excellence of their work. The simplicity and smoothness of working on the Brighton electrified line is a subject which is being considered, we understand, from every point of view by the boards of railway companies in all parts of the world.

Variable-Speed Polyphase Commutator Motors.

ELECTRICAL engineers have already become hardened to the illogical use of commutators with alternate-current machines, and the days have now passed when the absence of a commutator can be regarded as the chief asset of an alternating-current motor. So long as its continuous-current rival alone possessed the advantage of economical speed regulation, so long was the alternating current system at a discount. Gradually, however, the difficulties in the way have been overcome, one by one, and already various types of single-phase commutator motors, suitable for all kinds of traction and stationary work, are on the market. Nor were sparking troubles—so long the enemy of the continuous-current machine—to prove an effective hindrance to the new departure, for satisfactory means have now been discovered whereby these motors also have been made practicable.

IT was to be expected, therefore, that the three-phase motor, with its splendid starting torque and other qualities, would not long be allowed to remain behind in the matter of speed regulation. It is true that up to the present only machines of moderate output—equivalent to a few hundred K.V.A.—have been built, but it has already been conclusively proved that the three-phase commutator motor

Digitized by Google

is no less a success than the single-phase type. Were no other evidence at hand to support this, it would be quite sufficient to mention that almost, without exception, all the large Continental electrical firms have a special department set apart for the development of these machines. Whether this is actually a pleasant reflection for us here in England need not now be discussed, but certainly we cannot claim the lion's share in the development of alternating-current work, nor do we appear to be anxious to obtain it.

ALTHOUGH, as we have said, the three-phase commutator motor has not yet fulfilled all requirements, yet thereby it has been possible to impart to the induction motor the desired variable-speed characteristic. In our present issue we publish an article, by Mr. R. O. KAPP, showing how this is achieved by means of the cascade arrangement when the commutator motor alone cannot be satisfactorily built for the total output. In the main there are two systems whereby such cascade working can be arranged. In the one, due to KRÄMER, the commutator machine is mechanically coupled to the shaft of the main induction motor and receives from the slip-rings the energy which would otherwise be dissipated in resistance. In this way the slip-energy, less loss, is restored to the shaft and performs useful work. In the other system, due to SCHERBIUS, the slip energy is also taken from the induction motor and supplied to the commutator motor; but this latter machine now drives a generator, by means of which it pays back to the network an amount of energy proportional to the slip of the main motor, of course, minus the losses. A further advantage gained by the addition of a commutator motor is to make it possible to compensate for a lagging power factor. We need scarcely say that there are still several technical difficulties in the design of commutator motors of large output and high frequency, especially sparking difficulties, but the great strides already made cause us to be optimistic for the future.

British Engineering Exhibits at Brussels.

ON another page of this issue we publish some particulars of the visit of the British Press to the Brussels Exhibition, which took place last week, under the auspices of the Executive Committee of the Board of Trade Exhibitions Department, the Belgian State Railways, and the Commissioners of the Brussels International Exhibition. The technical Press was not particularly well represented, the majority of the delegates being drawn from the British daily papers. We have already dealt with the principal objects of electrical and engineering interest in the Exhibition in two previous issues, but the visit last week afforded us a special opportunity of gaining some impressions of the Exhibition itself. The members of the lay Press are not quite in the same position as the technical journals to appreciate the work which the British Government, through the Exhibitions Department of the Board of Trade, has carried out at Brussels and is carrying out in connection with other exhibitions. The delegates were brought into intimate touch with Lord LYTTON, the Chairman of the Executive Committee, and Mr. U. F. WINTOUR, the Commissioner-General, and gathered some idea of the difficulties experienced in making the British section of the Exhibition thoroughly representative of British art, science and industry. This matter is one upon which great emphasis should be laid, because it helps to explain in some measure the unrepresentative character of the British section of the Exhibition. Whether the British manufacturer is already convinced of the ineffectual nature, from a commercial point of view, of international exhibitions is, perhaps, a matter for some speculation.

IN an electrical and engineering sense, the British exhibits at Brussels are not anything like so impressive as the magnitude of British industrial achievements would lead one to expect. The number of electrical manufacturers exhibiting is small, and the machinery and apparatus shown gives a poor idea of the amount of capital invested in British electrical enterprises and the work which has already been carried out therewith. The difficulty of persuading English electrical manufacturers to exhibit at Brussels has probably arisen mainly on account of the comparatively small return which may be expected from the outlay involved. Belgian and French electrical industries are very much to the fore, but the exhibitors are naturally able to bring to the Exhibition men from whom they can directly expect to receive orders for plant and machinery. We understand that the duty on imported electrical machinery into Belgium is low, but it cannot be argued for a moment that the British electrical manufacturer would be able to compete in Belgium with the many firms there already well established and keenly intercompetitive. It is none the less a pity that this country cannot make a braver show at an exhibition of such industrial importance as that at Brussels. The executive staff of the Exhibitions Department have exhausted a voluminous and varied stock of argument in favour of an exhibit, but British manufacturers are slow to move in these matters and the result is disappointing. We do not think that it represents in any degree the amount of thought, energy and time which the Board of Trade Exhibitions Department have put into it. It does not appear to be in any sense indicative of lack of wisdom in the establishment of such a department by the Government; on the contrary it only serves to emphasise the necessity for further effort, the need for vigorous propagandist work amongst British manufacturers, and the desirability of driving home the international importance of fully representative British sections at all forthcoming international exhibitions.

Franco-German Cable Agreements.—Reuter's Agency states that, according to one of the leading German journals, as an outcome of the Franco-German cable agreement (referred to in our last issue) it is proposed to lay a submarine cable between Emden and Brest. It is also understood that the French Government will lay a cable from Brest connecting up with the now disused German cable from Emden to Valentia.

New Submarine Cable.—The Commercial Cable Co. has completed the laying and has opened for traffic a new submarine cable from Waterville, Ireland, to Weston-super-Mare, England, where it is connected with London by underground lines. The Company also announces that it has replaced long sections of submarine cable from Waterville, Ireland, westward, with a much heavier type of cable where the old cables had been disabled and in large part destroyed by fishing trawlers.

University of Leeds.—Arrangements have now been completed for the establishment of a professorship of Coal, Gas and Fuel Industries at the University of Leeds as a memorial to the late Sir George Livesey. Upwards of £10,500 has been subscribed to the fund initiated for this purpose by the Institution of Gas Engineers. In connection with the work to be carried out by the professor, an advisory committee has been formed, the members of which represent the University, the Institution of Gas Engineers and the Society of British Gas Industries.

Electrical Properties of Selenium.—In our issue of November 5th last, we described briefly some experiments by L. S. McDowell dealing with the rate of recovery of the normal resistance of a selenium cell after exposure to light. The recovery curves were found to resemble those for the decay of phosphorescence. In a recent issue of "The Physical Review" the author describes further researches on selenium, the recovery from excitation by X-rays being investigated. The results of the investigation are summarised as follows: The forms of the recovery curve for X-ray excitation and for light excitation are identical. The form of the recovery curve for excitation by light depends only upon the magnitude of the initial change in conductivity, and not at all upon the time required to produce that change. The rate of recovery from excitation by X-rays is slower than from excitation by light. Hence diffusion is probably not an important factor in producing the deviation from the straight line of the selenium recovery curves.

Carbon Brushes on Traction Motors.—A recent issue of the "Electric Railway Journal" states that the Virginia Railway & Power Co. have recently adopted the practice of slotting its commutators and using Le Carbone brushes in connection with them. This decision was the result of a series of careful tests carried out on a number of motors which had been giving considerable commutator trouble. After the commutators were slotted and used with the new brush, their wear was reduced to practically nothing. Not only was flashing largely eliminated, but it was also found feasible to adopt a lighter brush-holder spring tension. The old tension varied from 5 lb. to 15 lb. per holder according to the condition of the brush-holder springs. It is the practice of the Virginia Railway & Power Co. to reduce this pressure to 4½ lb. per square inch of brush contact area. The Le Carbone brush is also giving three to four times the life of the replaced brushes, a result which is due in part to the lowering of the brush-holder pressure.

Large Electro-Magnetic Clutch.—According to "The Times Engineering Supplement" a new method of driving a blast furnace blowing engine has lately been introduced by Messrs. Cochrane & Co., at their Ormesby Ironworks, Middlesbrough. Messrs. Cochrane, who utilise the waste gas from their blast furnaces to drive gas engines for dynamos and for blowing, found they had about 1,000 H.P. of electrical energy available, which they decided to utilise in driving a new blower. For this purpose a motor capable of giving 700 H.P. continuously, or 1,000 H.P. for one hour at 75 revs. per min., is direct connected to a vertical blowing engine, by Messrs. Richardson, Westgarth & Co., which has a flywheel weighing 23 tons and is 16 ft. 9 in. in diameter. For starting it was decided to adopt a method of gradual acceleration, and by arrangement with Messrs. C. E. Lugard & Co., of Chester, a Vulcan patent magnetic clutch has been utilised. The clutch fitted at the Ormesby Ironworks is stated to be the largest electro-magnetic clutch in the world, as it is 7 ft. 3 in. in diameter, weighs 6¼ tons, and is capable of transmitting 1,000 H.P. at 75 revs. per min. It was specified that the blower should be started up so gently and slowly that the demand from the gas engine generator would not exceed 1,000 H.P., and since its installation it has been possible to start up in one minute, the load on the gas-engine generator not exceeding 350 H.P. The electrical energy required to keep the clutch in operation is 2 kw.

Electrical Supply in the Potteries.—The first step in the unification of electrical supply in the Potteries having been taken by the appointment of Mr. C. H. Yeaman as electrical engineer of the new county borough of Stoke-upon-Trent, the future policy as regards the existing electricity undertakings is naturally arousing much local interest. The "Staffordshire Sentinel" last week published a prominent article questioning the advisability of the proposed expenditure of £15,000 for extensions to the Hanley electricity undertaking, and urged the necessity of a full and exhaustive enquiry as to the merits of the alternating and continuous current systems before any policy as to the future of electricity supply in the Potteries is adopted. The subject is treated on the assumption that continuous current alone is "fit to distribute" for immediate use. The single-phase 100 cycle system at Hanley—in contrast with the continuous-current system at Burslem, Stoke and Longton—although answering for ordinary lighting, is rightly stated not to be best adapted for power purposes and arc lamps. In proof of this, it is mentioned that the Hanley undertaking, which has been in existence for fifteen years, has but a relatively small power load, whilst the other more recent local systems are largely occupied in supplying current for power. In this connection it is interesting to notice that on February 28th last there were 1,077 H.P. of motors connected to the Hanley mains, whilst at April 30th the Burslem power connections totalled 1,033 H.P., and Stoke 1,057 H.P. It must be remembered, however, that power supply on an extensive scale is only a recent development, and the results at Hanley are certainly by no means unsatisfactory. The qualifications of the writer of the article for dealing with the subject are somewhat discounted by the fact that he calculates the value of the units unaccounted for at Hanley on the basis of the average cost *per unit sold* (2·40d.); and also by his explanation of the difference between continuous and alternating current, the latter, he explains, not being collected "continuously," but alternately, from different points, whilst in the direct current system the current is collected "continuously"!

Walbrook Telewriter Exchange.—This Exchange, of which a description was given in our last issue, was formally opened last Friday by the Lord Mayor of London, who transmitted by means of the telewriter the following message to the Postmaster-General: "The Lord Mayor congratulates the Postmaster-General on the opening of the Telewriter Exchange, which will enable the transmission of facsimile written messages within the City area. The enterprise of the National Telewriter Co. and the Post Office authorities in placing this facility at the disposal of the public should meet with cordial recognition, and I wish the undertaking every success." The Postmaster-General, in reply, expressed his interest in the telewriter and hoped the new Exchange would be successful. In addition to the arrangement with the Post Office whereby telewriter subscribers may transmit telegrams direct to the Central Telegraph Office, and also receive telegrams by the same means, it is interesting to learn that similar arrangements are being made with the principal cable companies. A telewriter exchange is also to be opened in the West-end of London for serving the theatres and large hotels, and a branch office will shortly be inaugurated in Manchester, so that it is hoped a complete system will in time be available throughout the country. The current which is employed for operating the instruments varies between 10 and 100 milliamperes, and is furnished from accumulators on each subscriber's premises. Eighteen cells are installed, and when the instruments are in use the cells at the receiving and transmitting ends of the line are in series, so that normally a pressure of about 72 volts is employed. For trunk line working, however, a pressure of 150 volts is necessary. The method of charging subscribers' accumulators is interesting. Charging is in progress whenever

Digitized by Google

the telewriter is not in use, current being sent over one of the line wires from a 60-volt battery at the Exchange. This current is only small, being limited by the resistance of the circuit, and an earth return is employed. In order to obtain accurate transmission of writing it is essential that the voltage employed should be constant. This result is obtained by a voltage regulator fixed at the side of each telewriter. The regulator consists of a moving coil in a permanent magnetic field, the position of the coil varying with the pressure of the accumulators. As soon as the telewriter is put in operation the moving coil is pressed on to the contacts of a rheostat, so inserting the necessary amount of resistance in the accumulator circuit. We notice that among the subscribers already connected to the Exchange are Messrs. Dick, Kerr & Co., and the British L. M. Ericsson Mfg. Co. It may also be mentioned that the latter firm manufacture the apparatus employed in the telewriter.

Current Topics.

Subjects of current interest dealt with in this issue include the following:—

Mr. R. O. Kapp contributes an article on "The Scherbius Motor and Some Methods of Working it in Cascade with Induction Motors."

We give a further account of the International Exhibition at Brussels. A party of press representatives visited the Exhibition last week as guests of the Commissioners.

In our Correspondence columns Mr. Béla Gáti gives some interesting telephonic results, and Mr. F. Jacob deals with the effect of leakance in loaded telephone cables.

The Electric Construction Co. have placed upon the market a new type of three-phase motor, the particular feature of which is the use of starting resistances, which rotate with the rotor and are automatically cut out step by step (20 to 30 per phase) by a centrifugal short-circuiting device as the speed rises. Thus the usual motor starter is eliminated and the simplest manipulation is secured.

Hampstead (London) Council have decided that, as far as possible, electric lighting shall be used in preference to gas in the public thoroughfares. In pursuance of this policy, the work of converting 237 additional lamps from gas to electric lighting, at a cost of £1,580, is to be commenced at once, and further conversions will be subsequently undertaken.

An inquiry was held on Wednesday at Carlisle into the application of the Corporation for sanction to borrow money for extensions of the electricity undertaking.

Parliamentary.—A House of Lords Committee has refused to sanction a clause in the Glasgow Gas Consolidation Bill to enable the Corporation to devote surplus profits to relief of rates.

The preamble of the Wimbledon and Sutton Railway Bill, which has already been passed by the House of Lords, has been found proved by a Select Committee of the House of Commons.

The Baker Street & Waterloo Railway and the London Electric Railway Amalgamation Bills have also passed the Committee stage, and have been ordered for third reading in the House of Commons.

Legal.—On Friday last Mr. Justice Parker dismissed a motion on behalf of defendants to discharge an order for trying issues as to two patents in Osram Lamp Works (Ltd.) *v.* G. M. Boddy & Co. The patents dealt with the manufacture of tungsten metal filaments, and the attachment of the filaments to the leads, and it was contended that it was undesirable to try the two together. For plaintiffs it was stated that the history of the two patents was practically identical, and that time and cost would be saved by trying them together.

INSTITUTIONS AND SOCIETIES.

Institution of Mechanical Engineers.—As already announced a joint meeting of the American Society of Mechanical Engineers with the Institution of Mechanical Engineers will be held in Birmingham and London, from July 26th to 30th. The proceedings will commence at Birmingham on Tuesday 26th inst., when the Lord Mayor of Birmingham and the members of the local committee will welcome the president (Mr. George Westinghouse) and members of the American Society of Mechanical Engineers and the president (Mr. John A. F. Aspinall) and members of the Institution of Mechanical Engineers. The reception will take place in the Lecture Hall of the Birmingham and Midland Institute and will be followed by the reading and discussion of Papers, whilst the afternoon will be devoted to excursions in the neighbourhood. The day's proceedings will conclude with a garden fête in the Botanical Gardens. Wednesday morning will be given over to the reading and discussion of Papers, and in the afternoon visits will be paid to local works. In the evening the Lord Mayor of Birmingham will hold a reception at the Council House. On Thursday, excursions to Coventry, Rugby, Warwick, Leamington, Kenilworth and Lichfield have been arranged. The centre of interest will then move to London, the Conversazione of the Institution of Mechanical Engineers being held on Thursday evening, 28th inst., at Storey's-gate, Westminster. On Friday morning, Papers will be read and discussed in the Lecture Hall of the Institution of Civil Engineers, whilst a dinner will be held in the evening at the Connaught Rooms, Freemasons' Hall, Great Queen-street, W.C. For Saturday, the 30th inst., excursions are being arranged. The Papers to be read at the meeting in London include the following:—"Electrification of Suburban Railways," by F. W. Carter; "Cost of Electrically Propelled Suburban Trains," by H. M. Hobart; "Economics of Railway Electrification," by W. B. Potter; "Electrification of Trunk Lines," by L. R. Pomeroy; and "Electrification of Railways," by G. Westinghouse.

Committee for the Protection of Electrical Interests.—The Hon. Arthur Stanley, M.P., has accepted the position of President of the Committee. Mr. Robert Hammond has agreed to act as Vice-President, Mr. Arthur H. Preece as Honorary Treasurer, and Mr. R. Borlase Matthews as Honorary Secretary. It has been arranged that for the present the Committee shall hold fortnightly meetings on alternate Wednesdays, and endeavours will be made as soon as possible to arrange for the formation of a Parliamentary Party in the House of Commons to represent electrical interests. We are informed that the Committee are making every effort to work in co-operation with other existing associations and societies, and all questions which can be dealt with by other associations are referred to them, the Committee endeavouring to secure for each society the general support of the collective electrical industries. The Committee have already had brought before them, and have under consideration, a large variety of matters, and it is felt that it will probably be necessary to make a selection of the more urgent or more important for their early attention. It would be a convenience to the Committee to receive notifications from time to time of matters which, in the opinion of any member of the industry, require to be dealt with, and it is suggested that any member of the industry, although not himself a member of the Committee, desiring any matter to be considered, shall communicate either with a member of the Committee or the Honorary Secretary, Mr. R. Borlase Matthews, Bank Buildings, Kingsway, W.C.

Royal Society of Arts.—The Society's Albert Medal, which is conferred annually for "Distinguished merit in promoting arts, manufactures or commerce," has this year been awarded by the Council to Madame Curie for the discovery of radium, which was due to the work of Madame Curie and her husband, Prof. Curie, jointly. Madame Curie is the second woman to receive the Society's Albert Medal, it having been conferred, in 1887, on H.M. Queen Victoria "In commemoration of the progress of arts, manufactures and commerce throughout the Empire during the 50 years of her reign."

Junior Institution of Engineers.—Sir J. J. Thomson, F.R.S., has been elected president in succession to Sir Henry J. Oram, K.C.B.

Royal Institution.—At the general monthly meeting, held on Monday last, the chairman, Sir James Crichton Browne, announced that His Majesty the King had graciously consented to become Patron of the Institution.

ARRANGEMENTS FOR THE WEEK.

FRIDAY, July 8th (To day).

Physical Society.

5 p.m. Meeting at the Imperial College of Science, Imperial Institute-road, South Kensington. *Agenda:* "A Thermo-electric Balance for the Absolute Measurement of Radiation," by Prof. H. L. Callendar, F.R.S.; "The Convection of Heat from a Body Cooled by a Stream of Fluid," by Dr. Alex. Russell; "On Hysteresis Loops and Lissajous' Figures, and on the Energy Wasted in a Hysteresis Loop," by Prof. S. P. Thompson, F.R.S.; and on "The Energy Relations of Certain Detectors used in Wireless Telegraphy," by Dr. W. H. Eccles.

SATURDAY, July 16th

Junior Institution of Engineers.

Summer meeting in Ireland. Reception at Trinity College, Dublin. Inspection of the Engineering School and visit to the Ringsend power station of the Dublin United Tramways Co. Reception (in the evening) by the Institution of Civil Engineers of Ireland.

THE VIBRATION GALVANOMETER.*

BY F. WENNER.

Summary.—The importance of the E.M.F. developed by the relative motion of the magnet and the winding of a galvanometer is pointed out, and the general theory of the vibration galvanometer is developed. A method of tuning is described possessing several advantages, and the principles to be followed in the design of a high-sensibility instrument for bridge work are considered.

The vibration galvanometer is an instrument for the detection of alternating currents or E.M.F.s. It differs from other instruments for the same purpose mainly in having the moving system tuned to the frequency of the current or E.M.F. to be investigated. If the period or frequency of the current is changed while the free period of the instrument is kept constant, it is found that the instrument has a high sensibility at and near the resonating frequency, while at frequencies differing by more than a few per cent. from the resonating frequency the sensibility is very small. The instrument, therefore, responds only slightly to the harmonics in the current or E.M.F. wave, so that usually no error is introduced when measurements and calculations are made on the assumption of a pure sine wave. This property makes the instrument especially suitable for those measurements in which frequency enters and in which null methods are used.

Max Wien† pointed out some of the advantages of a tuned instrument when he described his optical telephone, a vibration galvanometer in which the essential part of the moving system consists of a piece of soft iron on a very flexible diaphragm. Rubens‡ next brought out an instrument in which the mirror and soft iron piece are mounted together on a metal suspension instead of a diaphragm.

Max Wien§ later developed an instrument having a very small permanent magnet mounted on a brass wire suspension, the lengths and tension of which may be changed so as to give a considerable range in the number of vibrations per second. In 1907 Campbell‖ described a very convenient instrument of the D'Arsonval type. This instrument is suitable for frequencies of from about 50 to about 750 vibrations per second and is easily adjustable over this range. In sensibility this instrument compares favourably with Wien's when both are adjusted to the same frequency. Concerning the theory of the instrument, Campbell points out that the sensibility is independent of the moment of inertia and inversely proportional to the frequency. He also states that the damping is "both mechanical and electrical" and should be kept small.

Theory of the Vibration Galvanometer.—In any galvanometer, a current through the winding produces a force tending to cause a relative displacement between the fixed and moving system. The resulting relative displacement causes a part of the flux from the magnet to cut through the winding, and thus develops a counter-E.M.F. The energy available for producing a deflection is the time integral of the product of the current and the counter-E.M.F. As galvanometers are ordinarily used, this energy is small, due to the fact that after the moving system has reached a displacement equal to the final deflection the time integral of the product of the counter-E.M.F. and current is either equal to or less than zero. If the motion is only slightly damped, a reversal of the current at the end of the first deflection will cause a second deflection in the opposite direction larger than the first. This is due to the fact that the motion of the system again causes a counter-E.M.F., and thus more electrical energy is converted into mechanical energy. However, not all this energy is added to the system, since some is lost by air friction, induced currents, &c. By reversing the current at the end of each deflection the successive deflections can be increased until the average rate at which energy is lost by damping becomes equal to the average rate at which electrical energy is converted.

The author considers first the case where the impressed E.M.F. and current waves are both of a sine form and later the effect of harmonics. With a sine wave current and E.M.F. we may assume a simple harmonic vibration and a sine wave back E.M.F.

In use the free period is adjusted to or near that of the current to be investigated. If this adjustment is good the displacement of the moving system leads the driving current by 90 deg., and since the back E.M.F. depends upon the rate of change of this displacement it is in phase with the current. If, however, the tuning is not good the moving system leads the current by an angle greater or less than 90 deg., and consequently the phase angle between the current and the back E.M.F. is not zero. As the power converted depends upon the cosine of this phase angle, the tuning may have a marked effect upon the deflection. As the amplitude of the vibration increases the back E.M.F. increases, and unless the resistance is very high it has a marked effect on the value of the current. If the three vectors—the current, impressed E.M.F. and back E.M.F.—are in the same line, the power converted and consequently the deflection is a maximum, if after a steady condition is reached the back E.M.F. is equal to one-half the impressed E.M.F.

The relations between the amplitude of the vibration, current, E.M.F., frequency, &c., may be expressed in terms of the working constants, the more important of which are: (*a*) The current sensibility, (*b*) the E.M.F. sensibility, (*c*) the power sensibility, (*d*) the ratio of the back to the impressed E.M.F., (*e*) the time constant for current indication, (*f*) the time constant for E.M.F. indication, (*g*) the resonance range for current indication, and (*h*) the resonance range for E.M.F. indication. By resonance range is meant the fractional part by which the period of the current or the impressed E.M.F. is changed to reduce the deflection by half. These working constants depend upon the intrinsic constants of the instrument, which are: (*a*) The moment of inertia, (*b*) the moment of damping (by which is meant the ratio of the retarding torque to the angular speed when the coil is on open circuit), (*c*) the moment of restoration (the ratio of the torque, tending to bring the moving system to the null position, to the angular displacement), (*d*) the moment of displacement (the ratio of the torque produced by the current to the current), and (*e*) the resistance.

The author next states the fundamental equation and obtains a solution under certain conditions. Taking θ = angular displacement, α = moment of inertia, β = moment of damping, γ = moment of restoration, ψ = moment of displacement ρ = resistance of galvanometer, r = resistance of complete galvanometer circuit, I = effective value of current, f = frequency of current, f_0 = natural free frequency of moving system, $p = 2\pi f$, $p_0 = 2\pi f_0$, ϕ = amplitude after a steady condition is reached, E = effective value of impressed E.M.F., ω = the angle by which the impressed E.M.F. leads the current, η = the angle by which the impedance E.M.F. leads the current, σ = the angle by which the back E.M.F. leads the current, A = current sensibility, V = E.M.F. sensibility, A′ = direct current sensibility, W = power sensibility, D = ratio of back to impressed E.M.F., and r_1 = resistance of primary circuit. Then he shows

$$\phi = \frac{\sqrt{2}\psi E \cos\omega}{r\sqrt{p^2\beta^2 + \alpha^2(p_0^2 - p^2)^2 + p\psi^2\cos\sigma}}. \quad . \quad . \quad . \quad . \quad (1)$$

Or if $p = p_0$ σ becomes zero,

$$\phi = \frac{\sqrt{2}\psi I}{p\beta} \text{ and } \phi = \frac{\sqrt{2}\psi E\cos\omega}{p(r\beta + \psi^2)}, \text{ so that } \phi^2 = \frac{2\psi^2 IE\cos\omega}{p^2\beta(r\beta + \psi^2)}. \quad . \quad (2)$$

Defining the current sensibility as the ratio of the amplitude of the vibration to the effective value of the current, the E.M.F. sensibility as the ratio of the amplitude to the effective value of the E.M.F. at the terminals of the instrument, and the power sensibility as the ratio of the square of the amplitude to the power supplied gives

$$A = \frac{\sqrt{2}\psi}{p\beta}, \qquad V = \frac{\sqrt{2}\psi}{p(r\beta + \psi^2)}, \quad \text{and} \quad W = \frac{2\psi^2}{p^2\beta(r\beta + \psi^2)}.$$

In this $\cos\omega$ is taken as unity; this may generally be done without introducing an appreciable error, since in most instruments the impedance E.M.F., between terminals, is small in comparison with and very nearly in phase with the impressed E.M.F. The time constant is given for current indications by $T = 2\alpha/\beta$.

In those measurements in which the frequency enters and null methods are used, an exact balance cannot be obtained except when the E.M.F. and current waves are of a pure sine form. In practice this condition is seldom if ever fulfilled, so the vibrations caused by the harmonics may limit the precision attainable. One of the chief characteristics of the vibration galvanometer is that the amplitude of the various harmonic vibrations is small. This is because there is no resonance, and the turning moment changes direction at intervals short in comparison with the half free period of the moving system. The amplitude of the vibration produced by any particular harmonic in the E.M.F. wave is given by equation (1) above when the corresponding value of p is substituted.

By reference to equation (1) it will be seen that the denominator can be decreased (if ψ is large in comparison with $r\beta$) by a decrease in $\cos\sigma$, even though in so doing the first term is increased, as it necessarily is when the instrument is thrown slightly out of resonance. If at the same time $\cos\omega$ can be kept near unity, the deflection will be increased. By referring to a vector diagram it will be seen that if a large inductance is placed in the galvanometer circuit, so as to make the angle η nearly 90 deg., and the frequency of the impressed E.M.F. is increased slightly, so that the angle σ assumes a negative value somewhat less than 90 deg., it is possible for the back E.M.F. to be much larger than the impressed E.M.F. and the latter still have the larger component in phase with the current. The combination of the inductance and the slightly high frequency of the

Digitized by Google

impressed E.M.F. results in bringing the back and impressed E.M.F. somewhere near quadrature, and the latter somewhere near the phase of the current. If the frequency of the impressed E.M.F. is not too much above the resonating frequency, the result may be an increase of the component of the current in phase with the impressed E.M.F. This means an increase in the power supplied to and consequently an increase in the amplitude of the vibration of the moving system. A condenser in series with the galvanometer and the lack of tuning in the opposite sense should give corresponding results.

In expressing the sensibility or deflection it will be convenient to use as the unit of current the microampere, of E.M.F. the microvolt, of power the micro-microwatt, of deflection a millimetre broadening of a line image 1 metre in front of a plane mirror ($=25\times10^{-6}$ radians), and C.G.S. units for the other quantities. The resistance must then be expressed either in ohms or electromagnetic units to correspond with the quantities with which it is associated. When the sensibility is expressed in the arbitrary units or the resistance in ohms, it will be here indicated by a line over the symbol representing the quantity.

The intrinsic constants can all be determined from five independent measurements. Measurements which are easily made and from which the constants can readily be calculated are: The resistance, the direct-current sensibility, the current sensibility, the E.M.F. sensibility and the resonating frequency. Then

$$\alpha=\frac{0{\cdot}91(\bar{A}-\bar{V}\rho)}{f_0^2\bar{A}A'\bar{V}},\qquad \beta=\frac{8{\cdot}1(\bar{A}-\bar{V}\rho)}{f_0^2A^2\bar{V}},$$

$$\gamma=\frac{36(\bar{A}-\bar{V}\rho)}{f_0\bar{A}A'\bar{V}},\qquad \psi=\frac{90000(\bar{A}-\bar{V}\rho)}{f_0A\bar{V}}.$$

Basis of the Equations.—In the derivation of the equations, it has been assumed that the moving system experiences an angular acceleration proportional to the resultant torque, a retarding torque

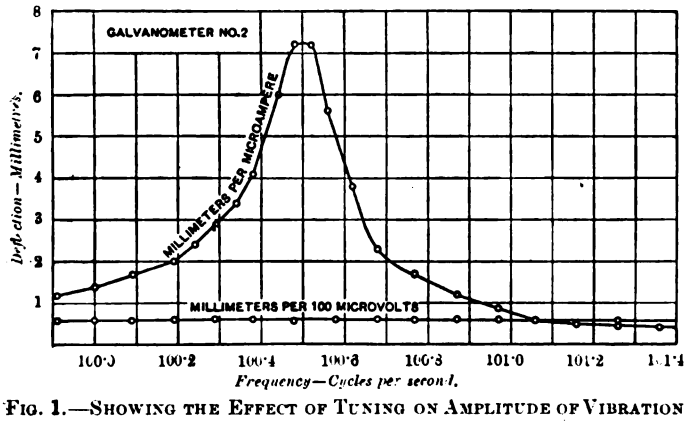

FIG. 1.—SHOWING THE EFFECT OF TUNING ON AMPLITUDE OF VIBRATION WITH CONSTANT CURRENT AND CONSTANT E.M.F.

proportional to the angular speed, a restoring torque proportional to the angular displacement, and a displacing torque proportional to the current and independent of the displacement and the rate of change of the current. That is, (*a*) the moment of inertia, (*b*) the moment of damping, (*c*) the moment of restoration, and (*d*) the moment of displacement are all constant. It is further assumed that harmonics in the E.M.F. or current wave produce no effect on the behaviour of the instrument toward the fundamental, but cause an additional vibration depending upon their magnitude and frequency. It should be mentioned that the effect of the time constant of the circuit, which is generally small in comparison with the time constant of the instrument, has been neglected. If the time constant of the circuit is large it may materially affect the rate of change of the amplitude of the vibration.

Method of Tuning.—The method first used consists of applying to the terminals of the galvanometer a small alternating E.M.F. and adjusting its frequency or the free period of the moving system until a maximum deflection is obtained. This is the method usually used and for some purposes it is very satisfactory. In general, however, the change in amplitude of the vibration with a change in tuning is small, especially near resonance. If the tuning is made in this way, and observations taken for the E.M.F. and current sensibility, a correct value is obtained for the former, but there may be an error of 50 per cent. or more in the latter. If, however, a high resistance (of the order of 100,000 ohms) is placed in series with the galvanometer, an E.M.F. of suitable value used, and the adjustment made for a maximum deflection, the tuning is very much better. This gives a sufficient accuracy in the tuning for most purposes, including the determination of the constants.

However, even with the high resistance a sufficient precision in the tuning could not be obtained for some of the work. It was therefore necessary to use some other method, and the one chosen makes use of the phase angle between the displacement of the moving system and the driving force. On the shaft of the generator is mounted a large disc, behind and slightly above which is placed the line source of light. The disc cuts off about half of that portion of the line which it is desired to use except when exposed by notches, one for each pair of poles, cut in the edge. These notches are so placed with respect to the windings that they expose the lower half of the line only at the instant when the E.M.F. is a maximum. Relatively large resistances are used, especially in the galvanometer circuit, so that the resonance curve is sharp and the current may be assumed to be in phase with the E.M.F. One observes then a band of light above and a line of light below the edge of the disc. When the tuning is good the line appears below the centre of the band. When it is disturbed the line moves toward one side or the other, depending upon the sign of the disturbance, and the displacement is considerable before the shortening of the band is appreciable. A glance at the image tells at once the sign and gives an indication of the magnitude of the lack of tuning so that the adjustment can easily and quickly be made. By using a large resistance in series with a galvanometer having a small moment of damping, this method indicates a lack of resonance when the difference in the frequencies is of the order of 0·01 per cent. of the resonating frequency.

Galvanometers Used.—The galvanometers used were one of the Rubens type made by W. Oemke, one of the Campbell type made by R. W. Paul, and one built in the Bureau of Standards' instrument shop. The galvanometers are referred to below as Nos. 1, 2 and 3 respectively. No. 3 was designed with the idea of getting an accurately balanced system of known moment of inertia and of investigating the effect of air pressure. The general construction is

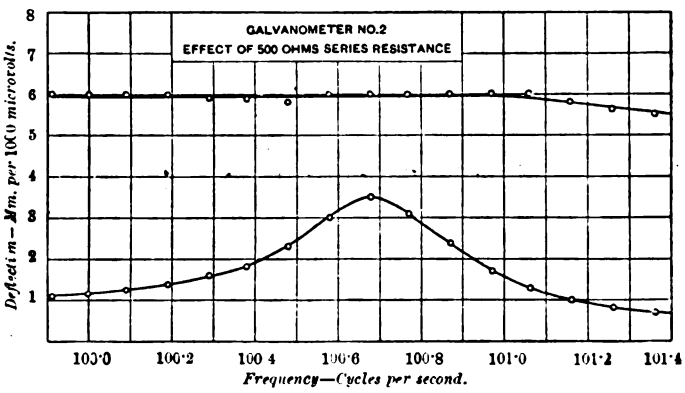

FIG. 2.—SHOWING EFFECT OF RESISTANCE IN DECREASING AMPLITUDE OF VIBRATION WITH CONSTANT E.M.F. IN THE CIRCUIT.

somewhat like the Rubens type, except that a single magnet is used. The constants of these galvanometers are tabulated in the Paper.

Some of these constants are given in the following table, whilst Figs. 2, 3 and 4 show further characteristics.

—	Galvanometer No. 1.	Galvanometer No. 2.	Galvanometer No. 3.
Alternating current sensibility	1·5	7·3	4·2
Direct current sensibility	0·018	0·10	$5{\cdot}5\times10^{-4}$
E.M.F. sensibility	0·0014	0·0061	0·0075
Resonating frequency	100	100	100
Resistance	231	30	71
Power sensibility	0·0021	0·045	0·032
Resonance effect	39	116	2,700
Ratio of back to impressed E.M.F.	78%	97·5%	87%

An inspection of the curves will show that resonance has a marked effect upon the amplitude of the vibration. It seems to have been the idea that the effect of resonance* was to increase the sensibility by about 100 times. Taking the ratio of the alternating to the direct current sensibility gives: for No. 1, 83; for No. 2, 730; and for No. 3, 7,600. If, however, by the effect of resonance we mean the ratio of the amplitude produced by a certain amount of power supplied at the resonating frequency to the deflection produced by the same amount of power supplied by direct current, these figures are too large, since no account has been taken of the back E.M.F. A matter closely associated with the resonance effect is the change

* Campbell, "Phil. Mag.," 14, p. 497, 1907.

Digitized by Google

in the ratio of the amplitude of the vibration to the current, with changes in the frequency of the latter. This ratio in the neighbourhood of the resonating frequency is shown by Fig. 1, for galvanometer No. 2, and it will be seen that the ratio has a sharp maximum at 100·5 cycles per second and falls to one-half for a change of 0·14 per cent. in the frequency. Fig. 2 shows the ratio of the deflection to the E.M.F. at the terminals of the instrument and when 500 ohms are placed in series. The 500 ohms in series makes the resistance of the circuit 18 times larger, yet at the resonating frequency the ratio of the deflection to the E.M.F. is reduced by only about 45 per cent. It is evident, from the behaviour of this instrument, that when it is used in bridge work with a constant impressed E.M.F. the resistance of the galvanometer circuit, if under 300 ohms, has but little effect upon the sensibility.

The effect of air damping on galvanometer No. 3 is shown by Fig. 3. It will be noticed that the air reduces the resonating frequency by about 0·75 per cent. This change in frequency is accounted for if we assume that the system drags with it a quantity of air whose moment of inertia is equal to that of a sphere of air having a radius slightly larger than the radius of the disc. It is also to be noticed that the removal of the air makes the resonance curve much sharper. The effect which is of real importance is the reduction of the sensibility by the air friction. Since the back E.M.F. is proportional to the amplitude, the power supplied per micro-ampere is, according to the curves, about 9 per cent. less when air damped. For the same deflection, then, the power supplied, when air damped, is about 11 per cent. greater.

Fig. 4 shows for galvanometer No. 2 the effect of a large inductance on the ratio of the amplitude of the vibration to the E.M.F. The inductance used was the 480-volt winding of a 600-watt transformer and the increase in the ratio was 125 per cent. While the resonating frequency was 100·52, as shown in Fig. 1, yet the maximum amplitude of vibration occurred with a frequency of 101·03

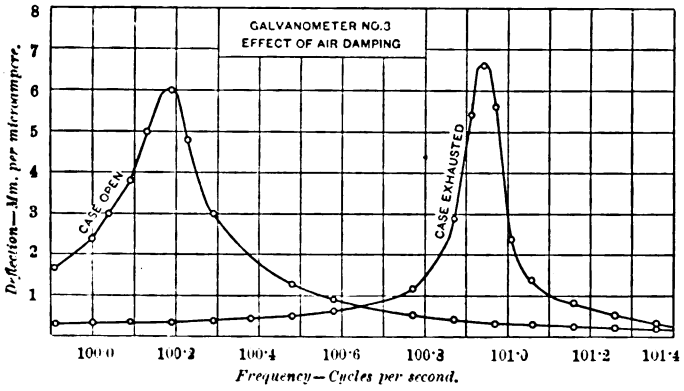

FIG. 3.—SHOWING CHANGES DUE TO AIR DAMPING, IN RESONATING FREQUENCY, SHARPNESS OF TUNING, AND CURRENT SENSIBILITY.

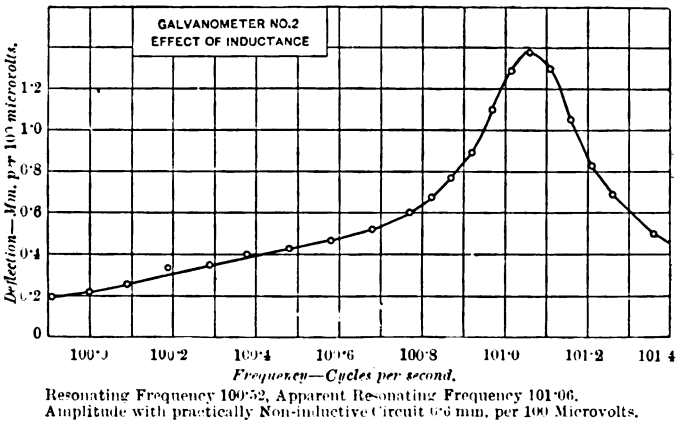
cycles per second. The effect observed was much more marked with an inductance about a quarter as large. No effort was made to get an inductance of the most suitable value.

The consideration of the precision which may be attained in the balance of any one of the alternating current bridges will show the bearing of some of the above work on problems of this kind. To illustrate this the author chooses the comparison of the product of a capacity and self-inductance with a frequency by the "series" method. The advantage of using a transformer with an instrument developing a relatively large back E.M.F. is also shown. Where a transformer is to be used, equation $\rho = r'(1-D)$ serves to determine the ratio which makes the sensibility of the whole combination a maximum. Since in well-designed and constructed instruments the power necessary to maintain a vibration of any specified amplitude depends only slightly upon the resistance or the ratio of the back to the impressed F.M.F. (provided this ratio is over 75 per cent.), the condition for maximum power converted is at least very nearly the condition for a maximum sensibility of the combination. This equation will therefore be of service in determining conditions which will give the best results with a particular instrument. The use of a transformer in connection with a galvanometer reduces the resistance of the galvanometer inversely as the square of the step-up ratio without changing its power sensibility or the ratio of the back to the impressed E.M.F.

Design.—A brief consideration of the theory and data given above will bring out a few of the principles involved in the design of vibration galvanometers. The consideration will be limited to instruments to be used in circuits of fairly low resistance, generally under 500 ohms and low E.M.F. This is the condition met with in alternating-current bridge work which at the present constitutes the main field in which the vibration galvanometer is used. The instrument may be connected directly in series with the circuit, or to the secondary winding of a transformer the primary of which is connected in series with the circuit. When the galvanometer is connected directly in series with the circuit, the relation between the amplitude of the vibration, the impressed E.M.F. and the various intrinsic constants of the instrument is given by equation (2). It should be noticed that the amplitude is a maximum for a particular value of the moment of displacement, that is, when $\psi^2 = r\beta$. This signifies that the mechanical power received by the moving system is a maximum when the back E.M.F. is equal to one-half the F.M.F. impressed on the circuit. With galvanometer No. 2 used on a bridge having a resistance of 100 ohms in each arm it will be seen that ψ^2 is about eight times as large as $r\beta$. As ψ is proportional to the field strength of the magnet, it follows that a reduction of 60 per cent. in the field strength results in an increase in the sensibility of the combination of about 70 per cent. This change results in a decrease of about 40 per cent. in the power sensibility. Where $\psi^2 = r\beta$, equation (2) takes the form $\phi = E/p\sqrt{2r\beta}$. As r is made up of the resistance of the galvanometer and the arms of the bridge in a series parallel combination but little is to be gained by making the resistance of the galvanometer excessively small. In inductance and capacity bridges p is generally fixed from other considerations, so we have β as the only factor under this condition which materially affects the sensibility of the combination. The power necessary to maintain a vibration of a given amplitude is proportional to the moment of damping. *The design then should be such that the back E.M.F. is approximately equal to one-half of the E.M.F. impressed on the total galvanometer circuit, and the mechanical power necessary to maintain at the chosen frequency a vibration of any particular amplitude should be as small as possible.* It is necessary also to take into



Resonating Frequency 100·52, Apparent Resonating Frequency 101·06.
Amplitude with practically Non-inductive Circuit 0·6 mm. per 100 Microvolts.

FIG. 4.—SHOWING SHIFT OF APPARENT RESONATING FREQUENCY AND INCREASE OF AMPLITUDE OF VIBRATION DUE TO INDUCTIVE CIRCUIT.

consideration the resolving power of the optical system to be used, as this often limits the amplitude of vibration which may be detected. Where the galvanometer is to be used regularly with a transformer the ratio of the back E.M.F. to that impressed at the terminals should be large, though there is little to be gained by making it over 90 per cent. Here, as before, the moment of damping, or the mechanical power necessary to maintain at the chosen frequency a vibration of any particular amplitude, when the circuit formed by the winding is open, should be as small as possible.

It will be seen that the moment of inertia of the moving system does not affect directly the sensibility. It does, however, affect very materially the resonance range and the sensibility to the various harmonics. Where the balance depends upon the frequency or the wave-form the moment of inertia should be relatively large. On the other hand, where the balance is independent of the frequency, and especially if no special device is available for controlling the frequency, the moment of inertia should be very small to make the resonance range large. We have seen that the power lost by air friction by galvanometer No. 3 for a vibration of unit amplitude is 3·5 micro-microwatts. If we assume that 75 per cent. of this is lost by friction and pressure against the mirror we see that the power sensibility of a galvanometer having a frequency of 100, a mirror 1 cm. in diameter and operating in air is limited to 0·4, or about 10 times the sensibility of galvanometer No. 2. The sensibility may be made higher than this by changing the shape and reducing the surface of the moving system, yet if a very marked improvement is to be made in the sensibility it may be necessary to do away with the air damping by placing the instrument, or at least its moving system, in a vacuum.

PUBLIC LIGHTING FROM A MUNICIPAL POINT OF VIEW.*

BY JACQUES ABADY.

Summary.—The author first considers the different forms of street lighting contracts which are in vogue and discusses the relative merits of each form, reaching the conclusion that to buy street lighting by light value is the most advantageous course. He then passes to the question of the position of the lamps and the distribution of the light, emphasising the fact that street lighting in many cases degenerates into a haphazard scheme of point lighting. He urges the desirability of decreasing the candle-power of light units and placing them closer together.

To the casual observer the question of public lighting appears to be, no doubt, a simple and straightforward matter, involving no more difficulty than placing lamps upon columns, lighting them when dusk approaches, and extinguishing them at the break of day. As a matter of fact, however, the problem is one of very considerable difficulty because it concerns so many diverging interests. The public, for instance, as it becomes more and more used to improved lighting in dwellings and shops, expects that the lighting of highways will keep pace with such improvements, but does not, of course, expect to pay more for it. The municipality has to consider the question of cost, and its relation to rateable value; while those supplying the light regard public lighting as something of an advertisement, and naturally enough desire to introduce whatever improvements may be forthcoming from time to time.

Although, from a municipal point of view, the form of illumination would appear to be of secondary importance compared with the volume and distribution of the light itself, yet there is no doubt that the severe competition between gas and electricity almost invariably comes into fierce play when lighting schemes are under consideration; and the relative positions of gas and electricity might, perhaps, form part of a discussion upon the subject of public lighting. I am, however, free to admit that, given a light of a certain value, distributed in a certain manner, it does not seem of importance to the public whether that light is produced by gas or by electricity; the sole consideration should be the question of relative cost. It will, therefore, be more profitable to examine the following different forms of street lighting contracts which are in vogue:—(A) The contract for supply of energy with maintenance, payment being made for so much energy and not for so much light. (B) The contract for supply of energy only, maintenance being undertaken by a contractor acting for the municipality or the municipal public lighting department itself. (C) The contract for supply of light, payment being made for so much light irrespective of the energy required to produce it.

What are the relative merits of these forms of contracts, always assuming them to be equally well drafted in the legal sense, and how do they assure what I venture to point out as desiderata (which will be termed points 1, 2 and 3), viz., (1) The due observance of the terms of the contract entered into: (2) the efficient maintenance of the standard of lighting contemplated by both parties when the contract was entered into; (3) the facility or encouragement for either party to take advantage, during the contract period, of the introduction of improved methods, either to reduce the cost of producing the light, or to obtain a greater light for the same cost?

Let me say at once that I look upon a contract as something very difficult to draw up, but comparatively easy to break, in spirit at least; and it should be borne in mind that it is of the utmost importance that the terms of any contract should establish a mutuality or community of interest—that is to say, it should be to the advantage of both parties to keep to the terms agreed upon.

Contract A.—Point 1.—The due observance of the terms of this contract naturally hinges upon the facility for measuring the energy supplied. This may be gas or it may be electric current. If the former, it may be agreed to supply through burners with nipples which, tested in the laboratory at a certain pressure, will pass so much gas. To make such a test involves the removal of the burner from the post; and the removal and test of one or a few burners is no guarantee that the bulk are under the same conditions, nor that the pressure under which the burners are tested in the laboratory will be maintained in every street and at every lamp. This can only be ensured by a liberal and constant use of pressure recorders; and the presence of these might easily stop progress in the direction of improved means of gas distribution. If, however, the contract stipulates a certain consumption by the nipple test, and the maintenance of a certain pressure all over the district, with damages for failure in pressure, it will be seen that by this method a general penalty would be inflicted in respect to many lamps when a failure in pressure is found. Alternatively the agreement may involve the use of a governor at each burner; and, assuming for a moment the invariability of governors, their introduction is also unsatisfactory, because efficiency of incandescent gas lighting is hampered by limitation of pressure, and therefore the use of increased pressure should be encouraged and not discouraged, as it is by the use of governors.

These two methods of fixing the basis of payment, therefore, seem to fall short of efficiency, and are not to be recommended on this account. The further method of fixing the basis of payment is either by an average-meter system or by tests of consumption *in situ*; and as to these I think the former is unsatisfactory because it naturally induces a tendency to excessive consumption of gas, and does not ensure a community of interest; while the latter, the *in situ* method, is one which presents very considerable difficulty in carrying it out.

Examine the method of measuring energy as applied to electric current, and we find the same unsatisfactory state of affairs. If a lamp is removed and tested in the laboratory, there is firstly no guarantee that the pressure or voltage in the district will be the same as in the laboratory, and there is further, in the case of arc lighting no guarantee that the pressure is being effectively applied at the arc itself, or whether, instead, it is being reduced by the lamp mechanism.

Point 2 (the efficient maintenance of the standard of lighting).—Assuming bona fides and willingness on the part of the gas company, there is nothing in this form of contract to prevent the standard of lighting being maintained. From the municipal side, however, there would be considerable difficulty, in the case of a careless or unwilling gas management, in ensuring that the condition of the public lights shall always be satisfactory. New mantles might be fitted when required; but the quality of the mantles might be poor, and a poor illumination obtained, notwithstanding that the maintenance terms may be adhered to literally. Similarly with an electricity contract.

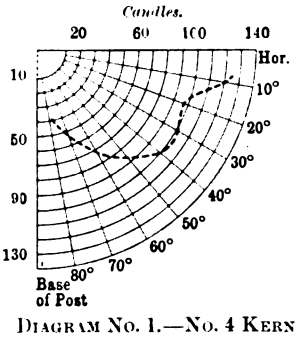

DIAGRAM NO. 1.—NO. 4 KERN BURNER, IN 16 IN. LANTERN.

Candle-power: 93 Candles.

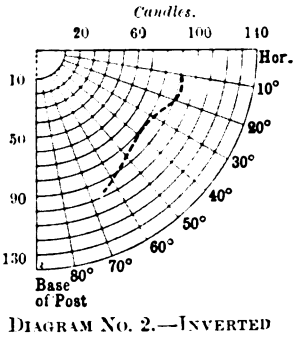

DIAGRAM NO. 2.—INVERTED BURNER IN LANTERN.

Candle-power: 86 Candles.

Point 3 (encouragement to introduce improvements).—In this important respect I think this form of contract is particularly weak. An example of the stop to progress and improved lighting which follows on this form of contract is to be found in an agreement entered into by the City of Westminster with the Westminster Electric Supply Corpn. It is for supply and maintenance of arc lamps and filament lamps, all to consume specified energy at a specified pressure at an inclusive charge per lamp per annum. This contract is, I admit, for a very long period; but this does not affect the point. Open arc lamps, with ordinary carbons and carbon filament lamps are used; and the consequence is that there is an enormous consumption of current for a poor lighting effect, whereas the substitution of more modern lamps would either enable the same light to be produced for very much less cost or a vastly improved light to be obtained for the same consumption of current. This example shows clearly how the public interests suffer from a contract of this nature.

Contract B.—Point 1.—This form of contract is to a great extent similar to the first form already discussed; and the preceding remarks with regard to the due observance of its terms apply.

Point 2.—With regard, however, to the efficient maintenance of the standard of lighting, it is on a different footing, for while it is obvious that the municipality has greater control over efficiency in this respect, yet it will be equally obvious that the interests of the contractor for the energy are very much at the mercy of the municipality. Thus, if the maintenance contractor neglects the maintenance, the energy contractor suffers; while if the municipal lighting department (taking, as it often does, the energy from another municipal department which is in competition with a com-

* Abstract of a Paper read before the Institution of Gas Engineers.

Digitized by Google

petitive form of lighting) is interested in doing what it can for its sister department, it is plain that the competitive form of lighting suffers, and real competition is at an end.

It would be affectation to deny that there are many corporations with a municipal gas (or electric) service, a lighting department, and an electricity (or gas) company in competition; and that the outside competitor is denied a fair chance, and on this account the public interest is sacrificed. From my municipal point of view, I hold this to be an unsound position, and I am trying to make clear how this sort of position can arise under the form of contract now being discussed. Where an outside contractor carries out the maintenance, the situation is almost as bad from the energy contractor's point of view, and certainly as bad from the public point of view. An instance of this is Marylebone. Here the gas company undertook to supply gas at so much per thousand. The borough employed a contractor to maintain. Tests which came under my immediate notice showed that the efficiency of the gas lighting was bad—due to insufficient attention to the burners and lamps. The Council, which owns an electricity service, was able to put forward a scheme of electric lighting which was obviously better than the results being obtained from the gas lighting; and so the gas company, whose position was prejudiced and whose hands were tied by the state of the gas lighting over which it had no control, lost the public lighting. This is put forward here as an example of the weakness to the contractor of this form of contract.

Point 3.—There is a position strikingly different from that under the first form of contract. Provided the contract does not limit the pressure of the gas supply, the municipality can obviously, if it chooses to pay for them, instal improved burners and give its public a better light, without affecting the contractor's position in the least. What it cannot do, however, is to give the same light by the introduction of improved burners, and so reduce the cost to the public of its lighting bill.

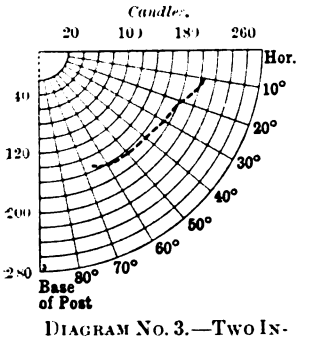

Diagram No. 3.—Two Inverted Burners in Lantern.
Candle-power: 174 Candles.

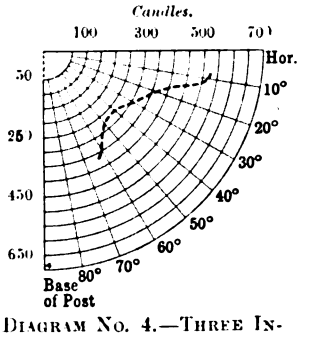

Diagram No. 4.—Three Inverted Burners in Lantern.
Candle-power: 319 Candles.

An interesting example of the contract in which the company supplies energy, and the municipality maintains, is to be found in the recently executed Calcutta Corporation contract, the salient clauses in which are set out in an appendix to the present Paper.

There appears to be one matter which both the "A" and "B" contracts seem not to provide for—that is, decreased quality of gas and increased pressure. Now it seems to me that a direction in which future improvements in the efficiency of gas lighting are to be found will be in a reduction of the quality of the gas, and an increase in the pressure at which it is supplied, so that by reducing on the one hand the amount of air theoretically required for perfect combustion, and increasing on the other hand the mechanical means by which that theoretical amount of air is obtained in practice, we shall be enabled to burn the right quality of gas under conditions of absolute maximum efficiency. Contracts "A" and "B" specifying as they do either (or both) consumption, pressure or quality, prevent improvements in the direction suggested.

In connection with contract "B," there is a point of very vital interest to the public which should not be overlooked—that of expense. It is obvious that there are limitations, both by statute and commercial expedieney, which govern the price at which it is possible or lawful for electric or gaseous energy to be supplied. There is, however, no limit to what a company (gas or electric) may do in the way of cheap maintenance; and so it will be found, I think, that "Energy + Cost of Maintenance by a Corporation Lighting Department" is, or may be, considerably more expensive than "Energy + Maintenance by the Energy Supplier." On the question of expense, again, where there is a contract "B," there is the possibility of a cheeseparing policy of maintenance being adopted by the municipality, so that for a more or less unimportant annual saving (too often a paper one), the efficiency of the lighting is sacrificed, and the odium falls upon the contractor for energy. The tendency to show savings on estimates is one which the average councillor finds almost irresistible.

Contract C.—Point 1.—The question as to control over the proper fulfilment of this class of contract is one about which there is undoubtedly considerable difference of opinion, and plenty of room for discussion; and, in order that there may be something concrete to discuss, in an appendix are set out the salient clauses of the contract for lighting entered into by the Westminster City Council. The testing clause is one to which attention is particularly directed, because this is the centre of gravity, as it were, of a contract which is for the supply of so much light. I am not personally responsible for the drafting of the clause, and frankly admit that there are many alternative methods of framing a clause to a similar effect. I append one hereto as follows:—

Each lamp is to be fitted with burners, mantles, globes, and fittings, as the case may be, giving a minimum of ——— standard candle power, respectively, as directly measured by the Council's portable photometric apparatus placed at an agreed distance above ground level, and is to burn ——— hours per annum in accordance with a daily schedule to be hereafter supplied by the Council. The fittings and lamp must be in every respect to the satisfaction of the city engineer; and in particular the reflectors above are not to be shaped so as to concentrate the illumination at the foot of the lamps, but horizontally flat or slightly convex or otherwise as may be approved by the city engineer, so as to disperse the rays. The tests will be taken in such a manner as to ensure that the glazing bars shall not interfere with the results obtained.

The candle power shall be arrived at by taking the average of two sets of readings in any position with regard to the light under test—one set at an angle of 20 deg. and a second set at an angle of 50 deg. to the horizontal. The photometer used shall be one working on the law of inverse squares, and so constructed as to read accurately whatever the respective colours of the light under test and standard light. Not less than three and not more than six readings, at regular intervals of not less than 30 or more than 60 seconds, shall be made at each angle; and the average of the readings shall be termed the reading or illuminating power at that angle. If, upon a test being made, the illuminating power of any lamp falls below the prescribed standard and is not more than 10 per cent. below it, a test may be made of each of the two nearest lights; and if the aggregate of the light from the three lamps equals the aggregate required by the contract, no damages shall be recoverable. The tests only to be made in reasonably clear weather—not during rain, mist or fog—and in the presence of a representative of the contractor should he so desire.

The intention of this contract is that the contractor shall assure himself, by continued test and inspection, that the lamps he provides are, during lighting hours, fulfilling in all respects the requirements of this contract; and he shall not claim relief from the conditions of this contract on the grounds of non-notification on the part of the Council of any failure to comply with the terms of this specification. The light given shall be of a steady, invariable character, of a white or yellowish white colour.

Now the questions that arise on this clause are two. Firstly, does the manner of applying the photometer test ensure an adequate fulfilment of the contract; and, secondly, is the method of making the test itself such as to remove all ambiguity and ground for dispute with respect to any test—in other words, is a photometer test sufficiently definite and certain? On the first of these points it should be observed that no question of gas or electricity consumption or pressure is involved, but merely a direct photometrical comparison at two definite angles; and the following is the reason why the two angles of 20 deg. and 50 deg. were selected. It must be recognised that to select any particular angles favouring one form of light would be most unfair. It will also be recognised that to take the mean hemispherical candle power is not practicable, as the comparison involves readings at each angle from 90 deg. to 0 deg., which is impossible with a test *in situ*, besides being a tedious matter. It will further be recognised by those who have studied street-lighting problems, that to include in such a photometrical test either of the angles of 80 deg., 70 deg., or 60 deg. would be highly undesirable, because it is at these angles (*i.e.*, in the vicinity of the lamp-post) that one usually gets an excess of light to the detriment of the rays thrown upon the area more distant from the lamp, and their inclusion would encourage, instead of discourage, the distribution of a large volume of light near the post. Now, it so happens that if the lighting curves of all types of lamps are examined—electric and gas, arcs, filament, upright and inverted mantles (high and low pressure)—it will be found that in the majority of cases the mean of the light given at 20 deg. and 50 deg. practically coincides with the mean hemispherical intensity, and therefore represents the value as candle power.

I emphasise the fact, before leaving this point, that there is no question of the light being defined by a foot-candle test; for one must admit that, had this been done, there would have been introduced all kinds of difficulties and problems (as to the behaviour of light rays with respect to surfaces and view point), about which photometrists themselves are not agreed. The test specified

Digitized by Google

involves simply the light of the lamp itself and the photometer. There is, moreover, no ground for ambiguity as to the meaning of the contract, because certain candle powers on columns of certain heights are specified throughout. Thus, in the competitive sense, it is a question of price against price for the supply of the same light without any quibble whatever.

The remaining question then is whether it is possible to test in such a manner as to remove all grounds for ambiguity and dispute. As a photometrist, I naturally see no difficulty at all in the matter. But it is possible that those who are not photometrists will look upon a photometer as a very indefinite and indifferent foot-rule indeed; and, of course, it must be admitted that it is necessary to define the kind of instrument and the way it shall be used, in the clearest possible manner. It appears to be quite satisfactory to take an instrument based upon the law of inverse squares, and in which such means of obviating reading errors—due either to colour difficulty or to stray light—are provided, as may be agreed upon between the parties entering into the contract. It is also quite simple to agree upon a definite primary standard of light; and it is equally simple to agree upon the secondary standard. This being the case, and it seems that these are all points which are demonstrable, What safeguards against error or chances of dispute should there be provided?

I think these are three—viz., (1) A definition of the weather in which official tests are permissible; (2) absence of infliction of damages if the two lamps nearest to a defective lamp are giving such light as will bring the average of the three up to standard; and (3) the presence of a contractor's representative should be permitted during any test. Upon the question of the practicability, in working, of such a test clause, it might be pointed out that in Westminster we have had five years' experience with a gas and electric light contract; and I am not aware of a single dispute, although defects have been found, charged and paid for. Further, as members will know, invitations were recently issued by the Westminster Council to the Gas Light and Coke Co. and to several electricity companies, to tender for lighting on this basis, and several offers were received. So certain, apparently, were the Gas Light & Coke Co. of the soundness of the basis of the contract and their ability to comply with its terms, that they quoted such prices as have not only ensured to them the continuance of the present gas lighting, but the transfer of several west-end thoroughfares which have been lighted by electricity for some years. And this is after they have had five years' experience of a contract on a photometer basis, made with a corporation which is most stringent in the carrying out of all its agreements.

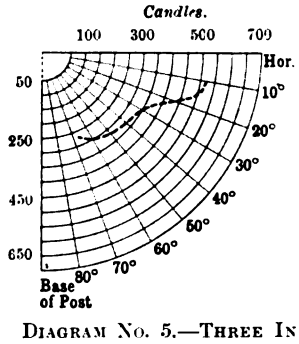

Diagram No. 5.—Three Inverted Burners in Lantern.
Candle-power: 368 Candles.

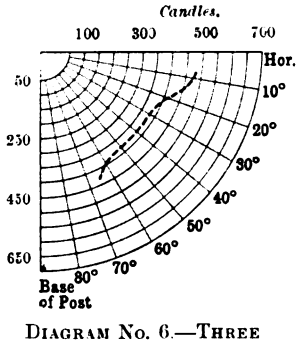

Diagram No. 6.—Three Metal Filaments in Lantern.
Candle-power: 387 Candles.

If, then, we assume the practicability of the photometrical valuation, how does this contract "C" affect the points 2 and 3?

Point 2.—It is unnecessary to labour the point that this contract ensures—so far as any contract can—"the efficient maintenance of the standard of lighting contemplated by both parties when the contract was entered into."

Point 3.—Does this contract facilitate or encourage the adoption by either party of improved methods? It seems to me that it does, because if the contractor finds he can produce the same light at a cheaper cost, or a better light for the same cost, he would surely approach the corporation and offer to share the benefit of such improvement. As an example of this, an incident occurred only last year when the St. James & Pall Mall Electric Lighting Co. approached the Westminster Corporation with an offer of this kind, which was accepted, and we have been obtaining two or three times the light originally contracted for, without any increase in annual cost. On the other hand, if the municipality wished to adopt, say, a new burner or lamp, consuming the same or less gas or electricity, and costing no more for maintenance, there would surely be no contractor so dead to his own interests as to refuse such a proposal. A clause to cover such contingencies should properly be inserted in the agreement; and under these circumstances it seems to me that contract "C" is best from a municipal point of view, and best for the contractor as well.

A great deal of the matter put forward does not apply with equal force to cases of a municipal light supply and municipal lighting department; but I suggest that if, as I think has been shown, it is practicable to buy and sell street lighting by light value, then that is the most direct, simple, and generally advantageous course.

Whatever arrangement, however, may exist in a town between suppliers of light and the local authority as to the contractual basis of the public lighting, it is plain that, from a municipal point of view, the selection of suitable units, the proper arrangement of them, and the general distribution of light are also questions of the utmost importance. And yet, if one may judge from specimens of street lighting, it is evident that these questions are very imperfectly understood; and in place of scientific arrangement of lamps of candle powers suited to the financial ability of a town, one often sees a motley and haphazard positioning of lamps, of all descriptions—exhibiting the crudest and most harmful contrasts of strong glaring light on one spot and next to none in another.

I am well aware that in many instances—too many instances—the suppliers of light have little or no voice in the selection of positions for lamps or the general drafting of lighting schemes; and it seems to me that this fact makes it all the more important that, by a clear grasp of the principles underlying the scientific arrangement of street lighting units, they should be in a position to offer criticism to lighting schemes which are open to criticism, and thereby gradually effect an improvement in public lighting on sound and rational lines. I therefore venture to draw attention to some statements of principles and facts, tabulated and collated, bearing upon the distribution of light, even though in so doing I may be travelling over well-worn ground and be laying myself open to the charge of being dogmatic.

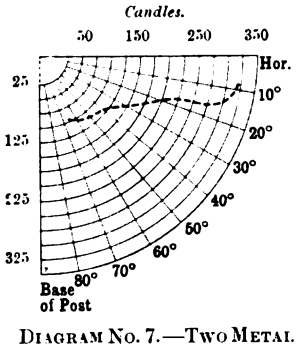

Diagram No. 7.—Two Metal Filaments in Lantern.
Candle-power: 161 Candles.

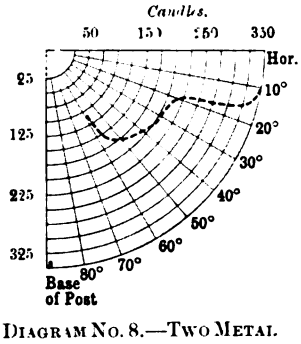

Diagram No. 8.—Two Metal Filaments in Lantern.
Candle-power: 201 Candles.

Now, the first point to be thoroughly grasped is that if one has a lamp of a certain candle power, the distribution of the light in the area affected by such a lamp will vary enormously—getting less and less as one gets more distant from the source of light. This variation in distribution depends upon the distance from ground level at which the light is placed; and, secondly, the proportion of light emitted at different angles. The author gives a table of measurements at various angles with different heights of the light source to render the point quite clear. It is seen that given a light of a certain candle power upon a certain height of column, if it is required to place it upon a higher column in order to illuminate a larger area, the light itself must be increased in candle power if the same illumination is required. In a second table are set out these two relative properties. Thus, suppose it is required to replace 11 ft. columns by 20 ft. columns, and get the same normal illumination, the candle power must be increased 3·3 times, but the area or length of street illuminated will be 1·78 times as large. That is to say, if there are 17·8 100 c.p. lamps 100 ft. apart in a road 1,780 ft. long, one would require 10 330 c.p. lamps 178 ft. apart to yield the same light. It will be gathered from this that, unless the relative cost of providing a 330 c.p. lamp is less than is the ratio of 3·3 to 1·78, then it would not be a paying proposition to make the substitution suggested in the example. The overlooking of this simple rule is the cause of much mystification of councillors, and much harm to public lighting. If it is overlooked, it might be said that 20 1,800 c.p. lights, which equal 36,000 candles (neglecting the rule referred to) will give twice as good a normal illumination as 200 90 c.p. lights, which equal 18,000 candles; and yet, of course, such a comparison

Digitized by Google

would be totally fallacious. But is not this sort of comparison made very often, and is it not only by a clear grasp of this question of relative distribution that one can deal with such fallacious comparisons? As a matter of fact, it is only when considering lights with reference to the same height from the ground that the candle power shows the true proportion of increase. Thus, 200 candles on a 15 ft. column is twice 100 candles on a 15 ft. column, but is not twice 100 candles on a 11 ft. column.

Before dealing with the part of the subject which I approach with some diffidence—viz., the proper spacing of lamps—I wish to make three points clear. Firstly, I reckon the distances in feet on a line parallel with the kerb to the nearest lamp, whether considering central lighting or whether the lamps are placed hit-and-miss fashion. Secondly, all such distances are approximate only, because naturally they will vary as the width of the carriage way varies. Thirdly, in considering the candle power on the ground surface, I simply divide the candle power at the angle by the square of the distance, and do not multiply by the sine of the angle of depression (equivalent to the cosine of the angle which the rays make with the normal to the illuminated surface). Had this course been followed, it would have been introducing something problematical, because the propriety of the application of the cosine law is affected not only by the angle of incidence, but also the angle at which the illuminated spot is viewed, by the nature or condition of the surface, and so on. I would point out, however, that had I multiplied by the sine of the angle of depression, I would be multiplying the disproportion of the lighting enormously, and making my point stronger; so that this multiplication is not omitted from any motive of "special pleading." Moreover, the object of street lighting is not only to illuminate the flat ground surface to which the sine multiplication only applies but also objects lying upon it and vertical moving figures as well. The figures given, therefore, are all comparative, and are literally true in terms of an imaginary surface receiving normal illumination.

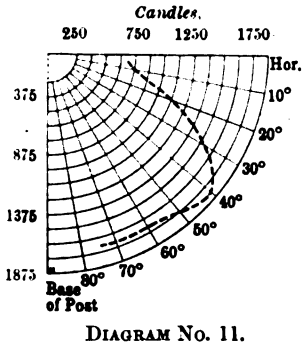

Diagram No. 11.
8-ampere Flame Arc
(Old Pattern).
Candle-power: 1435 Candles.

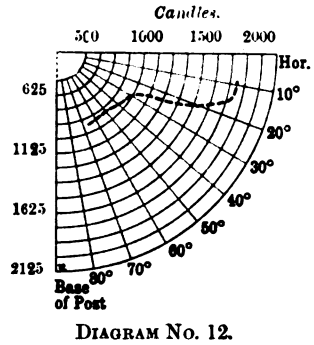

Diagram No. 12.
10-ampere Flame Arc.
Candle-power: 1926 Candles.

From the specific example in the first table mentioned above, it is seen that as between 80 deg. (near the column) and 10 deg. (away from the column) the illumination will decrease to $\frac{1}{32}$nd. If, therefore, one does not desire a greater unevenness of illumination than 1 to 32 (surely an enormous variation) one must place the lamps at a distance apart equal to twice the radius of the 10 deg. angle, so that the 10 deg. ray of one lamp meets the 10 deg. ray of the next. These approximate distances for various heights of light are as follows:—

11 ft.	125 ft.
12 ,,	136 ,,
13 ft. 6 in.	153 ,,
15 ft.	170 ,,
20 ,,	227 ,,
25 ,,	284 ,,

A variation of from 1 to 32 cannot be considered a satisfactory one; and it is a mistake to think that, in order to make the light stronger at the distant points, all that is needed is to increase the candle power of the source. Naturally, this does increase the light at the distant points; but it also increases the light round the column in the same proportion, and if carried to its extreme (as it often is), this course only results in a big glare of light round the column, which glare, by reason of the contrasts it introduces, makes the disproportion apparently worse. Reverting to the list set out above, if they are compared with the distances at which lamps are actually placed, it will be found that in many cases the distances are far greater, and that there are small areas of over-bright light and larger patches with practically none at all. Thus, through want of a little thought and the application of simple rules, street lighting in many cases degenerates into a haphazard scheme of point lighting, instead of being, as it should be, the even and uniform distribution of artificial light.

The more attention is drawn to it, the more will this disproportion of light diffusion and the unevenness of distribution probably be noticed, and it is hoped in course of time remedied. The question is, What can be done to improve this state of things, even though the standard set up for attainment is ideal? It appears to me that there are two ways. The first way is to select lamps with lighting curves which are greater at 10 deg. than at 15 deg., greater at 15 deg. than at 20 deg., and which get less and less as they approach the 80 deg. angle. To do this involves the use of dioptric arrangements or reflectors, and, of course, the disproportion can at best only be partially remedied. Attention may here be drawn to the polar curves in Diagrams 13, 15 and 16. These show what can be done by makers of electric and gas lamps if the necessity to do it is grasped

and insisted upon. A bad example is Diagram 11, a flame arc without dioptric globe. A bad example of a gas lamp is No. 2—an inverted burner in lantern.

The second way in which evenness of illumination can be procured, perhaps a costly method, but certainly an effective one, is to bring the lighting units closer together. It will also be possible to reduce the candle power of the sources of light, because there is always an excess of light near the column on account of the initial candle power necessary to give enough light at the distant points. I, therefore, urge attention to this view—viz., the desirability of decreasing the initial candle power of light units and placing them closer together. I am well aware that cost enters largely into the question of street lighting, and with this in mind suggest that it is better lighting to give a comparatively feeble but even illumination than it is to give a more powerful illumination full of contrasts

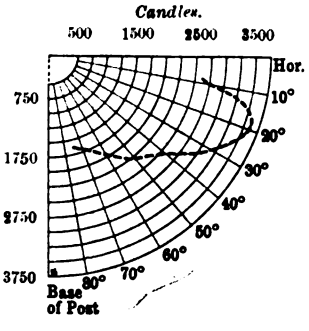

Diagram No. 16.—Three

between the light near the columns and that towards the midway position between them. I find that a suitable arrangement (though possibly an ideal one) of what might be termed "overlapped" lighting, is to plot the positions so that the 20 deg. angle of one lamp meets the 20 deg. angle of the next.

If this method sets up an unattainable ideal on account of cost, at any rate it sets up something to approach if not to attain, and indeed if the question of a suitable polar curve (greater light at 10 deg., 15 deg., and 20 deg. than at the nearer points) is also considered and properly made lamps insisted upon, then it is not necessary to do more than to arrange the distances so that the 15 deg. ray of one approximately overlaps the 20 deg. ray of the next, or

Digitized by Google

even overlaps the 15 deg. only. Applying these methods to the curves in Diagrams Nos. 13 and 16, we arrive at the following effects:—

	60°	50°	40°	30°	20°	15°	10°	10°	10°	
		10°	10°	10°	15°	20°	30°	40°	50°	60°
No. 13 ...	1·8	1·78	1·60	1·44	1·2	1·2	1·44	1·60	1·78	1·8
No. 16 ...	2·3	2·33	1·83	1·39	0·99	0·99	1·39	1·83	2·33	2·3

	60°	50°	40°	30°	20°	15°	10°	10°			
				10°	10°	15°	20°	30°	40°	50°	60°
No. 13 ...	1·8	1·55	1·37	1·44	0·97	0·92	0·97	1·44	1·37	1·55	1·8
No. 16 ...	2·3	2·2	1·7	1·39	0·78	0·68	0·78	1·39	1·7	2·2	2·3

Assuming, then, that either of these three arrangements is possible, or perhaps it would be better to say attainable, the distances are as follows, and in setting them out the distances for the first arrangement of lamps with practically no effective overlapping are repeated by way of contrast:—

Height of light.	10° meeting 10°.	15° meeting 15°.	15° meeting 20°.	20° meeting 20°.
11 ft.	125 ft.	82 ft.	72 ft.	60 ft.
12 „	136 „	90 „	78 „	66 „
13 ft. 6 in.	153 „	101 „	88 „	74 „
15 ft.	170 „	112 „	98 „	82 „
20 „	227 „	150 „	130 „	110 „
25 „	284 „	187 „	162 „	138 „

It is very difficult indeed to lay down any standard of lighting, and to say what lighting is suitable for a particular street. In all cases, naturally, positions have to be varied to coincide with street corners and to give greater light at crossings, &c., while the demands of a business street with heavy traffic will naturally not be the same as those of a residential street. Nor even if the demand were made or put forward in competition would the same type of light suit all streets. Thus, high unit lights on tall columns would be most unsuitable for a residential street, because the direct light produced at the level of bedroom windows is not to be desired. All one can do is to point out what effect, with respect to evenness of distribution, will be produced by various combinations of heights and distances. In case it will be of any guidance, I give some approximate particulars of some streets in Westminster; but in looking at these it should be borne in mind that when the new scheme of lighting is completed at the end of the year, the City of Westminster will be lighted by the following units spaced as regard heights and distances as nearly coincident with the figures given above, having regard to the character and needs of each individual street:—

Units now adopted by Westminster City.

12 ft. by 90 candles; 12 ft. by 180 candles; 13 ft. 6 ins. by 300 candles; 20 ft. by 1,800 candles; 25 ft. by 3,000 candles.

Extracts from the Calcutta Corporation street lighting contract and from the Westminster City street lighting contract are given in two appendices.

Constantinople Telephone Concession.—It is announced that the Council of Ministers have ratified the telephone concession for Constantinople granted some time ago to the British syndicate (represented by Mr. H. Laws Webb), and that the contract will be signed in Paris this week by the Minister of Finance. The concession runs for 40 years, but the Government can purchase the undertaking at the end of 10 years. A number of companies including the Thomson-Houston Co., the National Telephone Co., and the Western Electric Co. are interested in the concession. The installation must be finished within two years. It is thought that Salonica, Smyrna and Beyrout will shortly follow Constantinople's lead.

THE SCHERBIUS MOTOR* AND SOME METHODS OF WORKING IT IN CASCADE WITH INDUCTION MOTORS.†

BY REGINALD O. KAPP, B.SC.

Summary.—Although the three-phase induction motor has many advantages, it is at a disadvantage when a variable speed is required. This difficulty has been overcome to some extent by winding the motor so that the number of poles can be varied, and by cascade working, but such methods do not give the equivalent of the continuous-current motor. Another system is here described in which a three-phase Scherbius commutator motor is connected in cascade to the rotor of an induction motor, thus giving the necessary back E.M.F. to effect speed variation. The power given by the commutator motor may be used in various ways, such as on the main shaft or for driving a generator to return power to the mains.

Three-phase current has such very great advantages over direct current that it has been employed in almost all cases where power in large quantities is used. The ease and efficiency of transformation of alternating current from the high voltage of the transmission line to that required by the consumer, as well as the saving in copper in the line, has caused three-phase current to be used more extensively as the supply stations for electricity became larger and more centralised, and recently, with the advent of the steam turbine, the advantages of three-phase generators over direct-current machines have become even more apparent. In fact, it is not yet possible to build direct-current generators up to the size and speed most suitable for working with steam turbines, whereas alternating-current machines have been readily adaptable to the conditions of

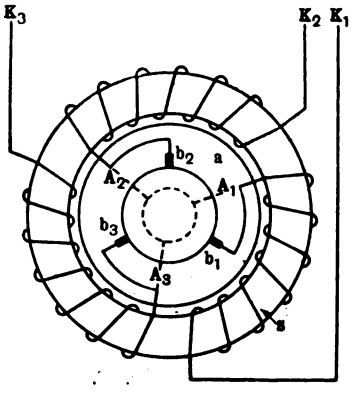

Fig. 1.

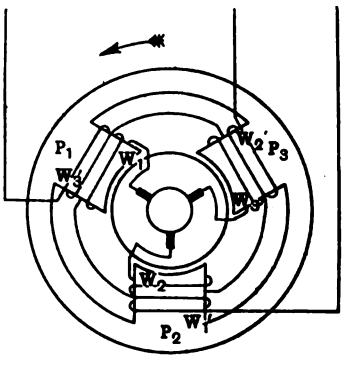

Fig. 2.

very high speed at which turbo-generators must run. From the consumer's point of view, the cheapness, simplicity and low cost of upkeep make three-phase induction motors the most suitable moving agent for machinery that does not require speed regulation.

Even when the speed has to be varied it is often found more desirable to couple an induction motor to the machinery to be driven rather than to transform the energy supplied from the network into direct current. The commonest method of regulating the speed of an induction motor, by inserting resistances into the rotor circuit, has the obvious disadvantage that a considerable amount of power is consumed as I^2R loss. Again, the speed may be altered by changing the number of poles. If the stator has two windings with different numbers of poles, it is possible to get four speeds. The principal disadvantages of such an arrangement for many kinds of working are that these speeds rigidly depend on the frequency of the supply current, intermediate steps are not possible, and the power factor becomes very bad, particularly for large motors running at a low speed.

Another method is the cascade working of induction motors. A second induction motor on the same shaft as the main motor is supplied from its rotor. If the cascade motor has one-half the number of poles of the main motor, the set will run at two-thirds the speed of the one motor alone, and the losses will be small. For more steps a third motor may be

* British patent No. 18,817/06. † British patent No. 16,087/06.

Digitized by Google

worked in cascade with the second, but the method cannot be extended indefinitely, as the power factor becomes very bad. In fact, for large machines running at a low speed the power factor is reduced so much that cascade working of even two induction motors becomes altogether impracticable. Intermediate speeds can only be obtained by the use of resistances.

Ideal electric driving for most cases would combine the use of three-phase current with a single motor capable of perfect speed regulation. These conditions have not as yet been fulfilled. They might be possible if a three-phase commutator

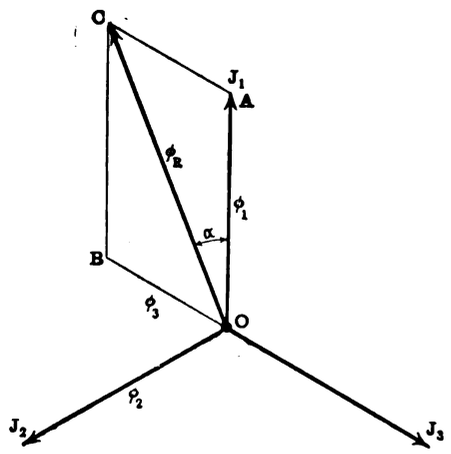

Fig. 3.

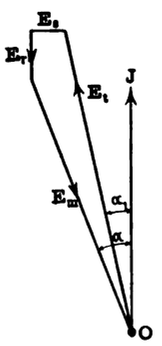

Fig. 4.

motor could be made to work directly on the mains. But technical difficulties in the design of commutator motors for large power and high frequency, particularly difficulties of commutation, have yet to be surmounted before such an ideal can be realised.

An alternative is the system of cascade working here described. An ordinary induction motor works directly on the mains, and has in its rotor circuit a three-phase commutator motor which supplies the necessary back E.M.F. to effect speed variation, and gives up the power it absorbs either to the main shaft or to some other shaft running at a constant speed, or drives a generator, which puts power back into the mains.

The advantages of this system are: (1) The speed can be regulated in as many steps as are required; (2) the loss of efficiency is very small; (3) the power factor can be improved, so that cos $\phi = 1$, thus making a smaller induction motor possible; (4) any required relation between speed and load is possible, as in the case of direct-current machines.

For satisfactory working on this system it is necessary that the behaviour of the commutator motor should be independent of the frequency of the current supplied to it. It is also important that it should commutate sparklessly when fed with current of various voltage and frequency and when run at varying speeds. These conditions are fulfilled by the Scherbius motor, and in consequence a system of cascade working has been perfected by Messrs. Brown, Boveri & Co., which employs a motor of this type.

The chief feature of the Scherbius motor is that it has the characteristics of a direct-current machine. The rotor is a drum-wound armature with commutator. The stator has two windings. One is for excitation, the other is a "compensating" winding. The latter is a drum winding arranged to be electrically an exact counterpart of the rotor. Its function is to counteract the transformer E.M.F. induced in the rotor by the rotating field. In a Latour or Heyland three-phase commutator motor the E.M.F. between the brushes is that induced in the rotor by the rotating field, and is proportional to the difference of speed between the field and the rotor. At synchronous speed this E.M.F. would be 0, at standstill a maximum. In the Scherbius motor the compensating winding is connected to the brushes in opposition to the armature, as shown in Fig. 1. The exciting winding is not shown. When the machine is at rest the transformer E.M.F.s generated in the compensating winding and the rotor are equal and vectorially opposed, so that the resultant E.M.F. between the brushes is 0. When the machine starts running the rotor E.M.F. becomes lower as the difference of speed of rotation between field and rotor decreases; but the E.M.F. induced in the compensating winding remains constant. These no longer balance and a voltage remains at the terminals equal to their difference. Eventually no E.M.F. is induced in the rotor, and the back E.M.F. is equal to that of the compensating winding only.

The motor runs equally well above synchronous speed if a higher E.M.F. is impressed, the back E.M.F. of the rotor and the compensating winding then acting in the same direction. It will be seen that the back E.M.F. is proportional to the speed, precisely as with a direct-current machine. A secondary advantage of the compensating winding is that it makes commutation easy for various reasons. Firstly, the effect of armature reaction is neutralised. Secondly, a field is produced in the neutral zone which cancels the reactance voltage in the short-circuited coils, so that the brushes stand exactly between the poles, and the machine commutates equally well when running at various speeds and in either direction.

In order to compensate for the lag of the current behind the voltage in the main motor, the commutator motor must have a leading current. To obtain this each field magnet is wound with separate windings from two phases, as in Fig. 2. The flux vector is then the resultant of the current vectors in the two phases, and its position depends on the proportion of the number of coils from each phase. In this way it becomes possible to produce any required angle between current and E.M.F. by choosing a suitable combination of the exciting coils. In Fig. 3 OJ_1 and OJ_3 represent the direction of the current vectors in phases one and three. The lengths OA and OB are

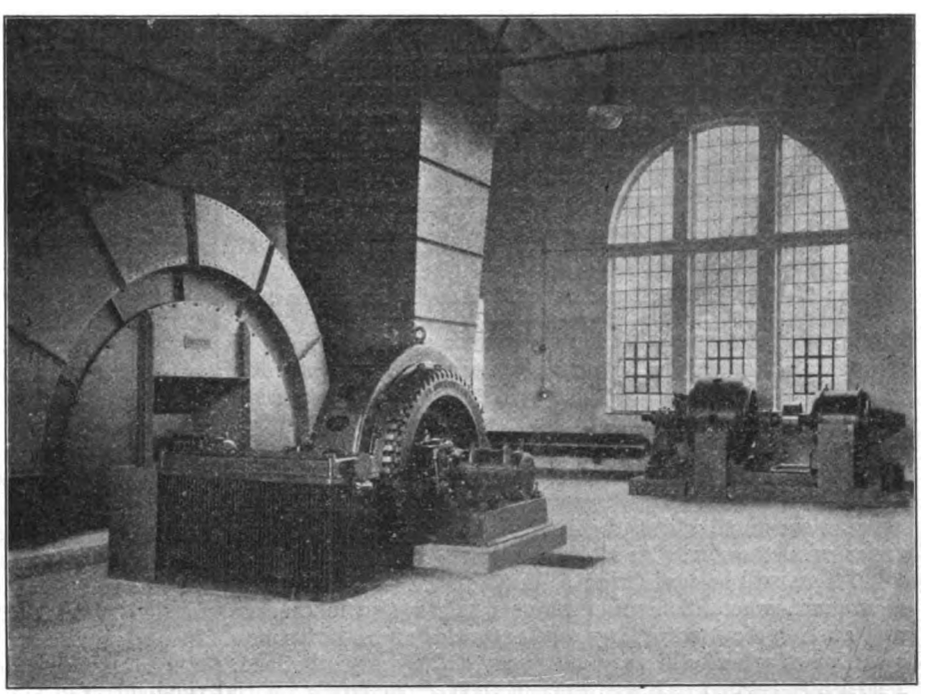

Fig. 5.—Fan with Electric Drive for Gelsenkirchen Bergwerks-Aktiengesellschaft, in Gelsenkirchen, Luftschacht Rheinelbe I./II., with Regulating Set in Background.

Digitized by Google

proportional to the number of field coils with which pole 1 is wound from each phase. Then these windings will produce fluxes ϕ_1 and ϕ_4, respectively, for which the ampere turn vectors can serve, and the resultant flux will be $\phi_R = OC$. As the E.M.F. of the machine is entirely due to rotation of the armature in the field, the E.M.F. is in phase with the flux. Therefore the vector of the back E.M.F. E_m in Fig. 4 has been drawn parallel to ϕ_R. If we make allowance for ohmic drop and self-induction, we obtain the vector of the terminal E.M.F. E_t, which is behind the current J by angle α_1. If the proportion of exciting coils are so arranged that α_1 shall equal the lag in the induction motor, the whole set will have a power factor equal to unity.

An advantage of this type of motor is that it may be shunt, series or compound wound, and in each case its behaviour is precisely the same as that of a direct-current machine, and these properties are imparted to the whole set when it is worked in cascade with an induction motor. If the motor is series wound, its back E.M.F. is, for low saturation, proportional to the current in the induction motor, that is to the load. The main motor will then run more slowly the greater the load, and we have the same effect as when a resistance is put into the rotor circuit, with the difference that the only loss is that in the machines themselves. If the motor is shunt wound, the back E.M.F. becomes nearly constant whatever the load is, as the flux is independent of the armature current. Further, the back

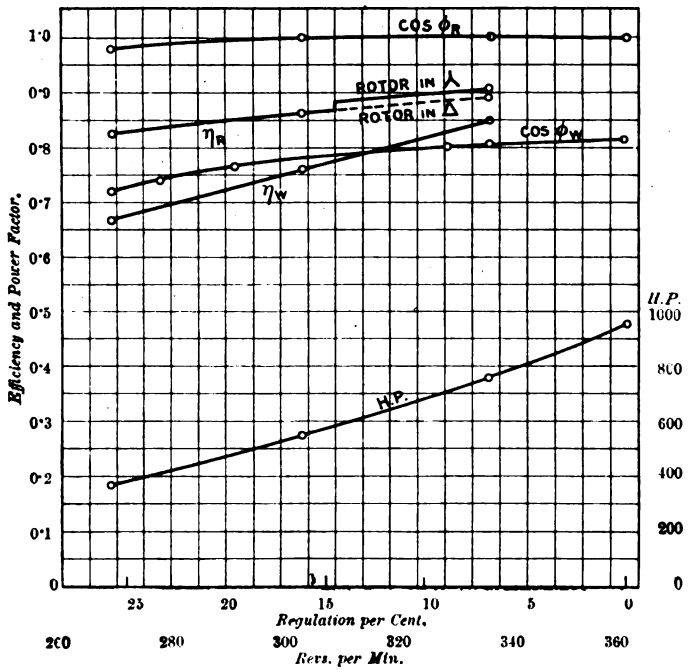

FIG. 6.—CURVES FROM TESTS ON THE SET AT GELSENKIRCHEN.

E.M.F. of the commutator motor depends on the strength of the field, that is on the amount of exciting current, and this equals the E.M.F. over the slip-rings divided by the resistance. As the resistance is mainly inductive, it rises with the frequency, that is with the slip. $E/\sim$ is constant if E is the E.M.F. of the rotor and $\sim$ the frequency of the slip. From this it follows that, if the cascade motor runs at constant speed, its E.M.F. remains constant, whilst the E.M.F. of the induction motor varies with the slip. At the point where both voltages are equal there will be equilibrium. Hence, by adjusting the field of a shunt-wound Scherbius motor which works in cascade with an induction motor, any constant speed of the latter may be obtained which will vary only very slightly with the load. This is not possible with any other method of regulating. With compound winding the speed may be arranged to drop by a required amount as the load increases, an effect often needed in rolling mills.

As any relation between load and speed is obtainable, this method of cascade working has become adaptable to the driving of machinery with very various conditions of working. The applications which have hitherto been developed are: (1) The driving of ventilating fans for mines; (2) the driving of rolling mills; (3) relief of the central station of sudden loads with the help of a flywheel; (4) the working of turbo air-compressors which require a motor that can run above synchronism.

As each of these is typical of different conditions of working, it is interesting to consider each one in detail.

It nearly always happens that for the first years a mine is worked the ventilating fans have to be run at a lower speed than they are built for, because the full draught is not required until the mine is completely extended. As the mine is built out, the power required for ventilation increases gradually, and to meet this increasing demand the fans are driven at a higher speed. If the fan is driven by a three-phase motor, and the speed regulated by resistances, energy is consumed day and night in these for several years, so that the efficiency of such a set is very low till it can be run at normal speed. With a commutator motor to regulate the speed the efficiency of the whole set is high and the power factor is unity. The curves in Fig. 6 compare the efficiency and cos ϕ for regulation with a commutator motor and with resistances. These curves are taken from an installation supplied by Messrs. Brown, Boveri & Co. to a mining firm near Gelsenkirchen in Westphalia. The fan has been supplied by Messrs. Schüchtermann & Krämer in Dortmund, and is capable of giving 230,000 cubic ft. of air per minute at a vacuum of 18·5 in. of mercury, when running at 363 revs. per min. When running at 268 revs. per min. it

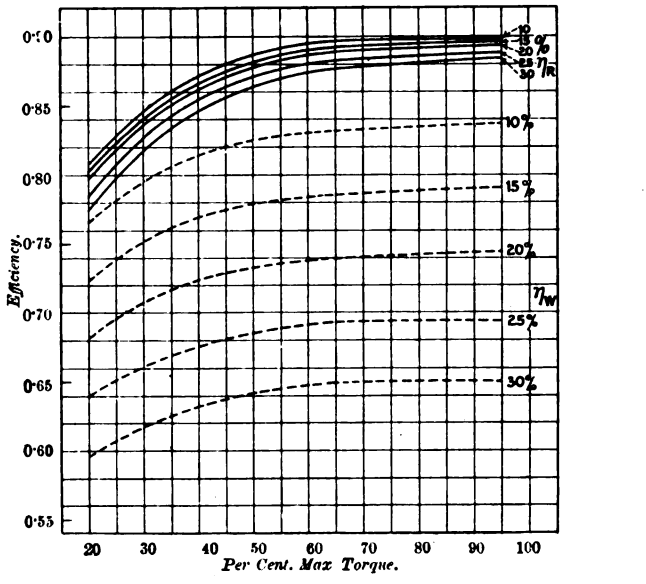

FIG. 7.—COMPARISON OF EFFICIENCY WHEN THE SPEED IS REGULATED BY RESISTANCES, AND BY A COMMUTATOR MOTOR ON THE SAME SHAFT AS THE INDUCTION MOTOR AND CONNECTED IN CASCADE WITH IT.

yields 150,000 cubic ft. of air per minute at a vacuum of 10 in. of mercury. This fan is driven by a three-phase induction motor for 5,000 volts and 50 $\sim$. It must give 1,000 H.P. at 363 revs. per min. and 370 H.P. at 268 revs. per min. At the present stage of the mine the lower speed is required, and this is achieved by a Scherbius motor connected in cascade across the slip-rings and driving an asynchronous generator, which works on the mains. Fig. 5 shows the whole set. The induction motor was designed for 850 H.P., but is enabled to give 1,000 H.P. on account of the phase compensation. The motor is able to work at 20 different speeds with a total range of 26 per cent.

The commutator motor is built for a power of 200 k.v.a., the generator coupled to it for 85 kw. The difference in size is accounted for partly by the losses in both machines; the power given back to the mains is, of course, that absorbed by the commutator motor less the losses. Besides this the current in the Scherbius motor has a considerable lead ($\cos\phi = 0{\cdot}7$) in order to cancel the lag of the main motor, but the chief reason for the difference in size between the two machines is that maximum E.M.F. and maximum current do not coincide. The torque of a fan is approximately proportional to the square

Digitized by Google

of the speed. Therefore at a low speed the rotor current in the induction motor is a minimum; the slip being greatest, the E.M.F. between slip-rings is a maximum. When the fan is running near synchronous speed the conditions are reversed. The load is high, so the commutator motor must take a high current at low pressure. It is necessary to build the motor for both conditions, so it becomes larger than the power it is required to take. The size can be reduced considerably by connecting the rotor of the main motor in mesh at low speeds and in star when the speed exceeds a certain amount. The current flowing into each brush is equal to $\sqrt{3}$ times the current per phase in the main motor when the connections are mesh and the voltage is equal to that induced in each phase. When the rotor

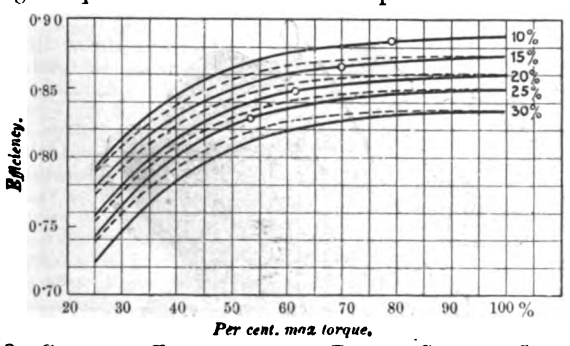

Fig. 8.—Curves of Efficiency for a Drop of Speed of 5 per cent. between No-load and Full Load.

is put in star, the brushes get a voltage equal to $\sqrt{3} \times$ phase voltage, and the current is the same as that flowing in the coils of the induction motor. By this means the cascade motor may be reduced to about 58 per cent. of the size it would have to be, without the change from mesh to star, if the range of speed variation is large.

The curves Fig. 6 were obtained from observed results after the plant was installed. Curves η_w and $\cos\phi_w$ were taken when the speed was regulated by resistances. η_R and $\cos\phi_R$ are for regulations with a Scherbius set. From 310 revs. per min. upwards tests were made with the rotor in star and in mesh connection. The curves show that there is some advantage as regards the efficiency in the change of connections. The curves in Fig. 7 have been calculated from measurements on the same set. They have, however, no bearing on the driving of ventilating fans, but they are interesting in connection with the application to rolling mills. The ordinates are efficiency, the abscissæ represent percentage of the maximum torque. Each curve is for a different constant slip. The curves were obtained from separate measurements on each machine, and assume that the regulating motor is on the same shaft as the induction motor,* so that the losses in the generator are done away with. In rolling mills it must be possible to apply any torque at any speed. Either a shunt or a compound wound machine is employed. With the former the speed remains practically constant with varying load. With the latter the series winding may be so arranged that the back E.M.F. rises by a fixed amount as the load comes on, producing a given drop of speed. This is often useful to enable the moving parts, which are usually designed to have a considerable moment of inertia, to supply a part of the maximum power.

Fig. 8 shows in the dotted curves the efficiency of a machine so compounded that a drop of speed of 5 per cent. takes place between running light and at full load.

In the driving of rolling mills, as of all machinery subject to large change of load, a flywheel combined with some means of automatically utilising the energy at moments of maximum demand, is indispensable. In this connection a system of relieving the supply station of sudden overloads with the help of a flywheel and a Scherbius set has been developed.* As in the well-known Ilgner system of working rolling mills, a flywheel is also employed to equalise the load, a comparison of the main principles of the two methods may be of interest. In the Ilgner system, where the supply current is three phase, the usual method is to have an induction motor, a direct-current generator and a flywheel on one shaft. The generator supplies current to a motor which drives the machinery. These two machines must be built large enough for the maximum power. The advantage of the flywheel is that the induction motor need only be large enough for a little more than the average power, and the load on the central station is kept almost steady. In order to cause the flywheel to give up its energy, resistances are put across the slip-rings of the motor, and thus a drop of speed obtained. It is also possible to lower the speed by strengthening the field of a commutator motor connected across the slip-rings. But the use of a commutator motor makes a different method of working with a flywheel possible, which has in some cases certain advantages over the system described above. Fig. 9 shows the connections of an equipment under construction for the Stordö Kisgruber in Norway. I is the main motor, and in this case a double commutator motor is used, of which the speed is regulated by means of the lever *h*. The flywheel is not on the same shaft as the motor, which takes the full power, but on the shaft of a separate set connected in parallel with the main motor. This set consists of the Scherbius motor *b*, the flywheel *c* and a three-phase induction motor all on one shaft. A current transformer, P, in the mains is connected to a relay, *r*; *t* is an autotransformer, through which the motor *b* is excited. When the load becomes heavy, the relay *r* works a regulating device in the autotransformer, which strengthens the field of the shunt-wound commutator motor *b*. This motor is connected across the slip-rings of *a*, which starts to run slower owing to the

* British patent 21,580/08.

Digitized by Google

increased back E.M.F. The flywheel is made to give up some of its energy and drives *a* as an asynchronous generator, which supplies current to the mains. In order that this may happen, the E.M.F. of *b* must exceed that across the slip-rings of *a*. The field of *b* must be adjusted so that this happens at the required speed. *a* will act equally well as a generator whether it be running above or below synchronism. In this method by far the greater part of the energy is taken directly by the working motor, and only that which varies above or below the average goes through more than one machine, so the efficiency is good. The efficiency is not much affected however great the drop of speed. In the usual arrangement, when the flywheel is on the same shaft as the motor, through which the full average power must pass, it is not advisable to drop the speed by more than about 14 per cent. when the flywheel energy is to be utilised, as a drop of speed is accompanied by a reduction of the output of the motor and of its efficiency. Therefore only a small portion of the energy stored in the flywheel can be taken out. When the flywheel is on a separate shaft it does not matter how far the speed of this is lowered, the main motor continues to give the same power, and so the flywheel is made use of to a much greater extent than with the Ilgner system. The flywheel may, therefore, have 0·5 to 0·3 times the weight otherwise required. Another advantage of the method that sometimes is important is that one set may be used to equalise the load due to a number of different machines, and the same set may serve to improve the power factor. A different method of equalising the load by means of a flywheel, and that also employs a Scherbius motor, is at present under construction for the power station at Bardonnecchia. This station generates three-phase current at 50 ∼, and a part of the power is to be used by the electric locomotives on the Mont Cenis tunnel, which require current at 16 ∼. For transforming the frequency three 1,800 kw. motor-generator sets are to be put down, each having a flywheel on the same shaft to keep the load on the main generators steady. The motors are ordinary induction motors. A Scherbius motor is to be connected across the slip-rings, and the field of this will be strengthened by the help of a relay at moments of heavy load. The power factor is automatically kept equal to unity.

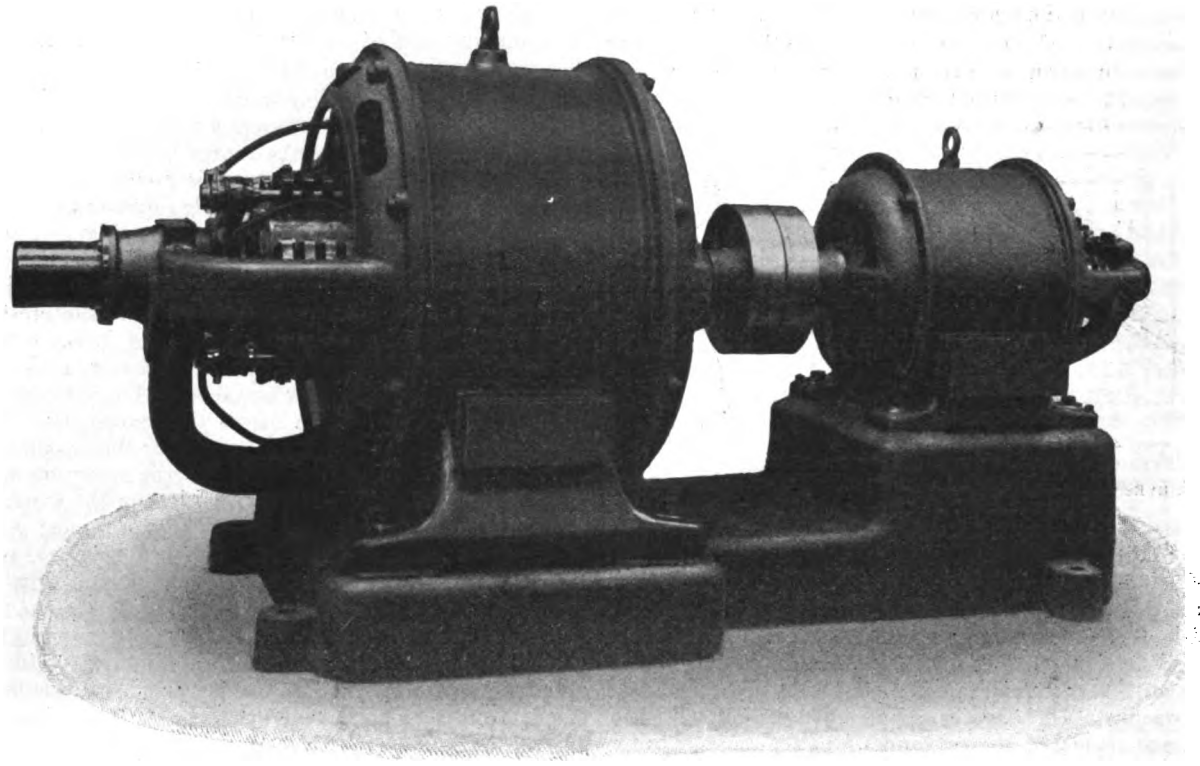

FIG. 10.—REGULATING SET FOR LES PETITS FILS DE WENDEL & CIE, KLEIN RÖSSELN, FOR A FAN MOTOR OF 300 H.P., 182 REVS. PER MIN., WITH 20 PER CENT. SPEED VARIATION.

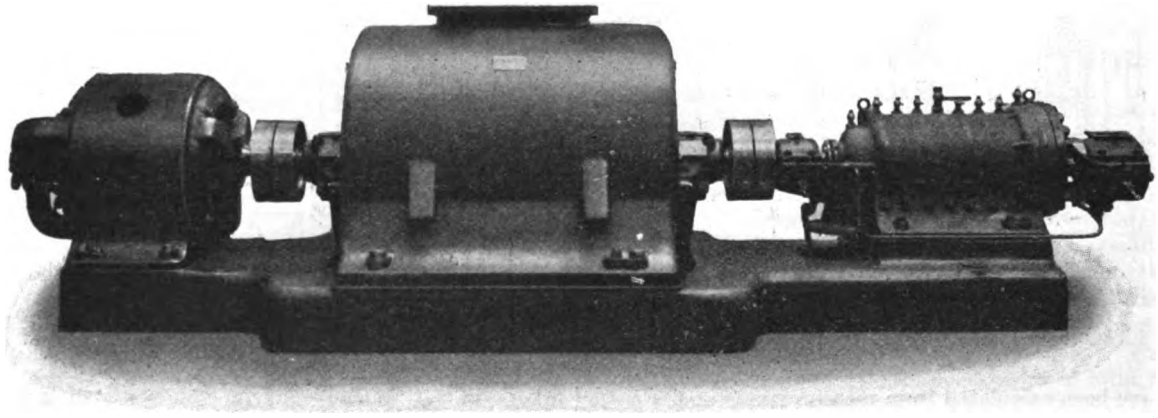

FIG. 11.—TURBO PUMPING SET FOR THE SOCIÉTÉ DES ACIÉRIES BOEL, LA LOUVIÈRE, BELGIUM, WITH COMMUTATOR MOTOR ON SAME SHAFT AS PUMP MOTOR, 225 H.P., 3,000 REVS. PER MIN., SPEED REGULATION 10 PER CENT.

What makes this system useful in the driving of turbo air compressors is the possibility of running above synchronous speed. At 50 ∼ a two-pole induction motor will run at $50 \times 60 = 3{,}000$ revs. per min. The most advantageous speed

for turbo air compressors is in many cases above 3,000 revs. per min., or between 1,500 and 3,000, so that it is too low for a two-pole and too high for a four-pole motor using current of 50 ∿. With a Scherbius motor working in cascade the set will run as well above synchronism as below, mechanical considerations alone limiting the speed, so that 3,000 revs. per min. at 50 ∿ can be considerably exceeded.

To make the induction motor run above synchronism it is necessary to impress on the rotor an E.M.F. equal to the vectorial sum of the ohmic drop and the induced E.M.F. due to the difference of speed of the rotating field and the rotor. Such a voltage can be supplied by a Scherbius motor working in cascade, as such a motor has a definite voltage, and supplies a direct current at synchronous speed, so that with a suitable method of excitation it is able to supply the current to the induction motor necessary for running at or above synchronous speed.

In conclusion, a table of equipments at the present moment either running or under construction, is appended which gives data of the induction motor and the commutator motor working in cascade with it for each case. Figs. 10 and 11 show two of the sets that have already been installed.

APPLICATION OF THE CRADLE-DYNAMOMETER TO THE TESTING OF ELECTRICAL MACHINERY.*

BY J. DAVIES AND F. SHAW.

Summary.—After referring to early applications of the cradle-dynamometer principle to the testing of electrical machines, the authors describe a dynamometer used at the Manchester School of Technology, the cradle being supported on ball bearings instead of the customary knife edges. Particulars of experiments with this machine are given, and also some results for the relation between hysteresis and eddy current loses and the flux density in the air-gap.

Introduction.—The essential part of a cradle-dynamometer is a steel framework provided at either end with an arrangement of knife edges, centres, or other suitable means for supporting it in such a manner that it is free to swing about a horizontal axis. The machine to be tested is mounted on a swinging platform, and the position of the machine is adjusted until the centre line of the shaft coincides with the line joining the points of suspension of the cradle. By means of counterweights moving along vertical standards the centre of gravity of the whole moving system, including the motor, may be raised or lowered at will. These weights are adjusted until the centre of gravity is slightly below the axis of suspension, and a third weight on the platform itself is adjusted until the moving system is in stable equilibrium with the platform horizontal. A pointer may be fixed to the frame in order to indicate the horizontal position.

When the machine is run as a dynamo the drag of the armature on the pole pieces, the friction of bearings and brushes, and also a portion of the wind friction, tend to rotate the entire moving system in the same direction as the armature is driven, the actual amount of deflection, *i.e.*, the sensitiveness, depending on the position of the centre of gravity and on the magnitude of the current in the armature and the losses in brush and bearing friction, &c. This rotational couple may be balanced by means of a calibrated spring balance or a sliding weight on a lever arm attached to the platform, and thus the pointer brought back to its zero position. When this condition is obtained, the sum of the unknown couples resisting the rotation of the armature is given by the reading of the balance or weight multiplied by the radius at which it is acting. It is then easy to calculate the total power spent in driving the dynamo if the speed is known, since horse-power $= 2\pi nT/33{,}000$, where n = revs. per min. and T = torque in pound-feet. The efficiency of the machine is obtained at various loads by measuring the output by means of suitable electrical instruments and dividing it by the input as obtained by the above method. If the machine being tested is a motor, and is loaded by causing it to drive another machine, the total input, including losses, is measured electrically and the dynamometer then gives the mechanical output. In either case the power generated may be supplied back to the mains, so that a complete heating and efficiency test can be performed without much waste of power.

Historical.—The first account of any tests being made on this principle appears to be in 1881, when the Rev. F. J. Smith tested the efficiency of some small direct-current dynamos by mounting their armature spindles between centres and then balancing the field system and frame by counterpoise weights. On driving the machine the magnet system was deflected and a weight applied to restore it to its original position. The machine thus became its own dynamometer.

Some time later, in the "Electrical World" (N.Y.), of January 5, 1884, Prof. C. F. Brackett, of Princetown, N.J., described a cradle-

* Paper read before the Manchester Students' Section of the Institution of Electrical Engineers; somewhat abbreviated.

Digitized by Google

dynamometer he had designed for testing electrical machines. The cradle was constructed of steel and was supported on knife edges. Machines as heavy as 4 tons were tested on this dynamometer. This form of apparatus has been called the "Brackett dynamometer," although Keith, in the "Electrical World" of January 19, 1884, claimed that a similar instrument was in use by the Fuller Electrical Co. (N.Y.) in the year 1879.

Dr. Drysdale, in an article on "The Testing of Electrical Generators and Motors," in "Engineering" of November, 24, 1905, after pointing out the inaccuracies in all indirect methods of measuring efficiencies and the disadvantages and waste of energy involved in the use of an absorption dynamometer, described a cradle dynamometer designed by him for the laboratories of the Northampton Institute. This dynamometer, with the machine in position, is shown in Fig. 1. In this arrangement the machine under test M is not mounted on the dynamometer, but is coupled up to another machine G, the frame of which is supported on ball bearings. In order to increase the sensitiveness the weight of the machine may be taken off the ball bearings by turning the hand wheel shown. The machine G is then supported on 10 knife edges, and Dr. Drysdale claims that this increases the sensitiveness many times.

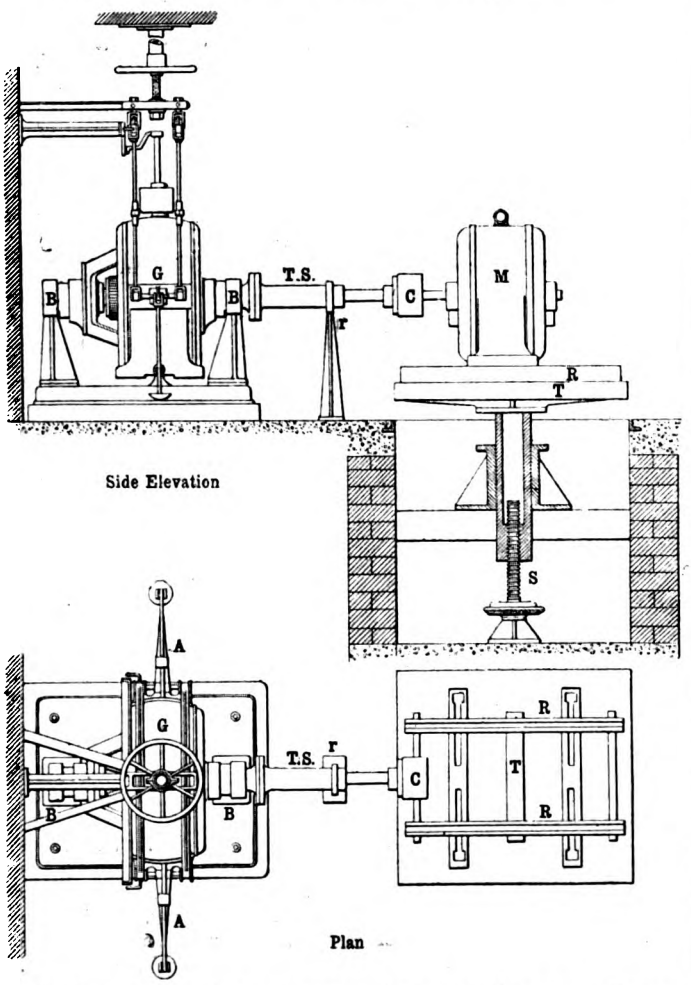

FIG. 1.—GENERAL ARRANGEMENT OF MOTOR AND GENERATOR TESTING PLANT IN THE ELECTRICAL ENGINEERING LABORATORY OF THE NORTHAMPTON INSTITUTE.

To determine the efficiency of a motor the machine G is driven as a generator, the power generated being supplied back to the mains. The dynamometer then gives the input to this machine, which is equal to the mechanical output of the motor. The load on the motor may be varied over a wide range by varying the excitation of the generator. The efficiency is obtained by dividing the mechanical output by the input measured electrically. In testing a dynamo the machine G is used as a motor, its mechanical output, which is now measured by the dynamometer, being equal to the input of the generator.

It appears to us that a cradle dynamometer supported on knife edges has the disadvantage of requiring the machines either to be direct-coupled or, if belt-driven, to have a vertical drive. These conditions are often inconvenient to attain in practice, and when to this is added the trouble due to wear and necessary adjustments when heavy moving masses are supported on knife edges, we are scarcely surprised that the cradle dynamometer, even with its great simplicity, has not achieved a larger measure of success.

In the dynamometer used by the authors, which was designed by Mr. A. E. Moore, of the Manchester School of Technology, the above mentioned difficulties have been done away with by supporting the cradle on ball bearings instead of knife edges. Figs. 2 and 3 show the dynamometer with a machine in position ready for test. The ball races BB are mounted on hollow steel cylinders $5\frac{1}{2}$ in. long and 2 in. in diameter, and contain steel balls $\frac{5}{16}$ in. in diameter. The object of having the ball races on hollow cylinders is to allow a shaft to pass through the end, so that, if occasion demand, a machine

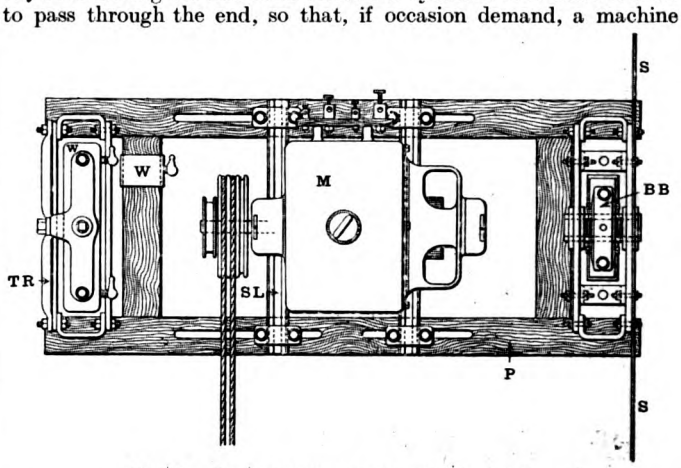

FIG. 2.—DYNAMOMETER USED BY AUTHORS.

under test may be direct-coupled to the driving or driven machine. The authors have found that, even with a tight belt drive, errors due to friction of the ball bearings can be made negligible (when the machine is running above 300 revs. per min.) when a torque of only 1 lb.-ft. is being measured. Fig. 4 illustrates the apparatus used.

Experimental.—Our first experiments were made with the object of finding out how the cradle method of determining the commercial efficiency of a machine compared with the other methods as regards accuracy and speed. We selected for this purpose a 3 kw. 200-volt enclosed machine made by the Electrical Co. The torque was measured by a Salter's spring balance, acting at a radius of 1 ft., and the speed by a direct reading tachometer driven from a small

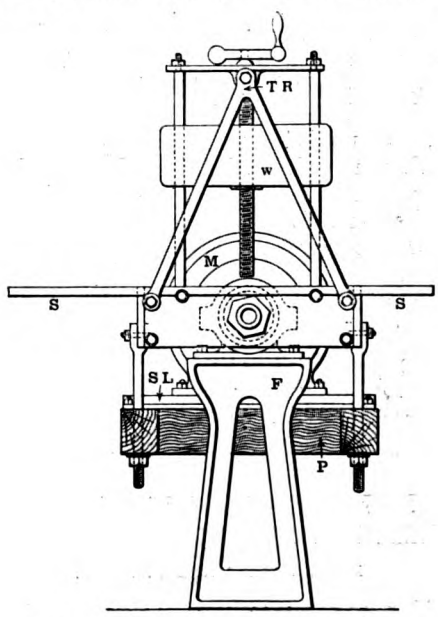

FIG. 3.—DYNAMOMETER USED BY AUTHORS.

pulley on the shaft. The results obtained are shown by the curves in Fig. 5 from which the efficiency, input and losses may be read for any output. The readings for these curves were obtained in about 15 minutes, and the authors have every reason to consider the dynamometer satisfactory for rapidly and accurately determining the efficiency of machines.

We were led to believe as the results of these tests that the cradle dynamometer might be employed for the purpose of making more refined measurements than those for which it has previously been used. As an example of its use for making delicate measurements we chose the problem of separating the various losses which occur

Digitized by Google

in a dynamo. Since the torque due to the losses was now only of the order of 1 lb.-ft. we abandoned the spring balance and used instead sliding weights on a lever 3 ft. long. The sensitiveness of the dynamometer was increased as much as possible by raising the counterweights, and in order to determine the horizontal position very accurately a small concave spherical mirror of 2 metres focus was fixed to the moving system, arrangements being made to form an image from this mirror on a vertical scale.

We first attempted to obtain the bearing friction loss by driving the machine without excitation and with brushes lifted. On comparing the results obtained in this manner over a wide range of speeds, it was found that there was no satisfactory agreement. It was thought this was due to the oil gumming, so the bearings were washed out and a better quality of oil was substituted. Various samples of oil were tried in this way, and the one which gave the best results finally adopted and used throughout in the subsequent work. Better agreement was now obtained although great care had still to be taken to have the temperature of the bearings constant while taking readings.

In order to separate the iron losses into their component parts, it is necessary to determine the total iron loss at various speeds. With this object in view the machine was driven for a long time at a particular speed and after about two hours, when the friction was constant, readings were taken of the torque produced when the machine was excited with a wide range of field currents. The torque due to iron losses was obtained by subtracting the frictional torque

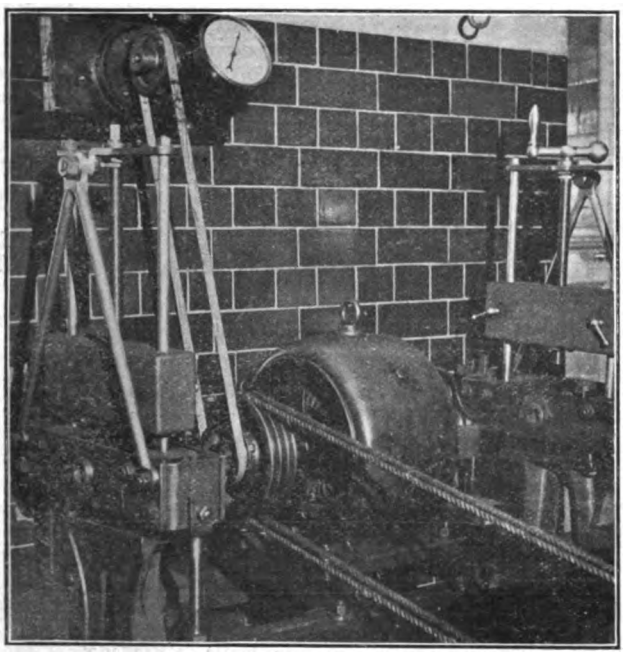

Fig. 4.—View showing Apparatus used.

from the total torque produced. This was repeated for a large number of speeds, readings being always taken for both directions of rotation. The mean of these readings, which did not greatly differ, was taken in order to eliminate errors due to imperfect centring and balancing. Another series of curves was plotted showing the relation between torque and speed for different values of the field current, but the results were far from satisfactory because theory clearly shows that there is a linear relation between torque and speed, whereas our curves show a tendency to bend downwards at low speeds. Much more reliable and consistent results, however, were obtained by reducing the end play of the armature of the machine tested, the readings so obtained lying very well on straight lines, as will be seen from Fig. 6.

It may be shown that the work done per revolution in overcoming hysteresis in the armature is, for a given flux density, independent of the rate at which the flux is being changed in direction. Thus, the torque due to hysteresis will, for given excitations, be constant and independent of the speed of rotation. If, therefore, the curves in Fig. 6 are produced to meet the axis of Y, the height of the point of intersection gives the torque due to hysteresis alone, because at zero speed the eddy current loss is nothing. It is also clear that for any speed and excitaiton the torque due to eddy currents will be equal to the difference between the height of the curve at that speed and the height at zero speed.

In order to obtain the relation between hysteresis loss and the flux density in the air-gap, the values of torque due to hysteresis were taken from Fig. 6 and values proportional to flux density were read off from the magnetisation curve. The law connecting these quantities was found by plotting log H against log B. It was found in this way that the hysteresis loss was proportional to $B^{1\cdot6}$ and the loss due to eddy currents proportional to $B^{2\cdot1}$. In connection with these results it is interesting to note that Mr. Dexheimer, in an investigation on "The Effect of Armature Teeth on Eddy Current Losses in Pole-shoes," found that the eddy current loss was proportional to $B^{2\cdot2}$ in the particular machine tested. Messrs. Wall and Smith in their Paper on the same subject (Proc., I.E.E., February 3, 1908) found the eddy current loss in pole-shoes to be proportional to $B^{2\cdot1}$.

Dr. Steinmetz has shown that the loss due to hysteresis in iron subjected to an alternating magnetomotive force—for example, in a

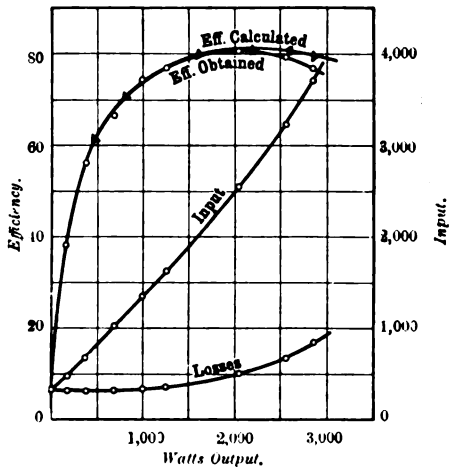

Fig. 5.—Curves connecting Output of Generator with Efficiency, &c.

transformer—is proportional to $B^{1\cdot6}$ between certain limits of B. The apparent discrepancy from this in our results may perhaps be explained in two ways. Firstly, the iron in a rotating armature is never de-magnetised as is the case with iron in an alternating field, but simply has its direction of magnetisation constantly changed. Secondly, the flux density in that part of the magnetic circuit where the loss actually occurs is much greater than the air-gap flux density and is probably very far from uniform. This second statement also explains why the index differs from 2 in the case of the eddy current loss, the fact that the divergence is less for eddy current loss than for hysteresis being probably due to the occurrence of a large part of the former loss in the pole-shoes, where the flux density is more like the flux density in the air-gap.

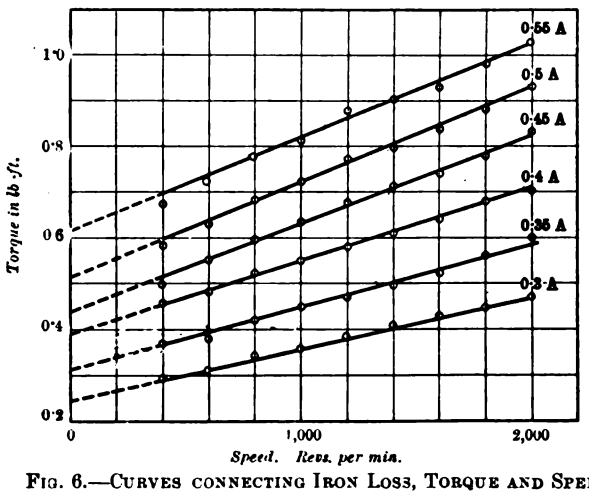

Fig. 6.—Curves connecting Iron Loss, Torque and Speed.

We do not wish to put forward the above as a complete explanation of the abnormally high value obtained for the hysteresis index, but we consider the unexpected result obtained rather suggests a suitable field for further investigation.

The torque due to brush friction was finally determined by measuring the torque produced by bearing and brush friction together, and subtracting that due to bearing friction. This was repeated for different speeds and the torque due to brush friction found to be practically constant over a wide range of speed. A remarkably good agreement was obtained between the observed efficiency and the efficiency calculated from the formula, output/(output + losses), the calculated value being slightly higher at high loads.

RAILLESS TRACTION.*

BY H. ENGLAND.

Summary.—The author first refers to the unsatisfactory financial results shown by the majority of tramways, and discusses the conditions under which a tramway running in a sparsely populated district can be made a profitable investment. At present railless traction seems to offer the only satisfactory method of extending operations. He then describes the various systems of railless traction in use and gives particulars of the working costs and cost of construction; and finally refers to the difficulty and expense in obtaining powers for the operation of railless schemes.

The qualified success of tramways and light railways laid in public streets has practically entirely stopped extensions into suburban districts. During the boom years, from 1897 to 1903, it was imagined that electric overhead trolley tramways and light railways would pay a substantial return upon the capital invested, even in suburban, inter-urban, and sparsely populated districts. Both municipalities and companies have been disillusionised, and when we glance at the Board of Trade Returns we find there overwhelming evidence of the fact that only in the larger cities and towns are tramways a profitable investment. In launching schemes for the construction of lines, neither municipalities nor company promoters have paid sufficient attention to the influence standing charges have upon tramway and light railway projects.

In my opinion, when first considering the prospects of a proposed undertaking, the first thing to be taken into account is the density of population to be served and the car mileage per mile of route the district will bear to return drawings at the generally accepted minimum figure of 10d. per mile. To illustrate the argument used in this Paper, I have taken throughout a route 4 miles in length, with a 16 hour car day, and 365 working days per annum. A tramway running in a sparsely populated district would be constructed with single track and passing places, and to bear a light service the cost of the cable would be small. I therefore estimate that such a tramway could be constructed for £40,000, or £10,000 per mile (not an extravagant sum). The interest and sinking fund repayments—calculating that the money would be borrowed by a local authority at 3½ per cent. per annum, and that the sinking fund repayments would be spread over a term of 15 years—would amount, to £5. 3s. 7¾d. per cent., and this on a capital of £40,000 would mean an annual payment of £2,072. 18s. 4d. I think it only reasonable to set aside for depreciation 5 per cent. on the capital employed; therefore the amount of capital account standing charges per annum would be £4,072. 18s. 4d. It may be argued that in the case of a company no amount would have to be set aside for sinking fund charges, but on the other hand, the shareholders would be entitled to some return upon their invested capital, and I think that £5. 3s. 7¾d. per cent. is not too much to earmark for this purpose.

The author shows in a table the standing charges per car-mile and the mileage per annum on the above basis for services from one minute up to 30 minutes. Thus, for a 10-minute service, the mileage per annum is 280,320, and the standing charges per car-mile 3·487d. This table clearly shows that with average working expenses of 6·504d. per car-mile it is absolutely necessary to run a minimum average 10 minutes' service, and that any less frequent service cannot possibly pay.

It may be said that a less frequent service, with a higher return per car-mile than 10d., would be profitable; and although better traffic drawings per car-mile would neutralise the higher standing charges, still I do not think it is sound policy, or good for the ultimate success of any undertaking to fail to increase the car service when the receipts amount to 10d. per car-mile.

It must be understood that I am now discussing a suburban car service, because in large cities and towns it is often quite impossible, and indeed inadvisable, to run a service to keep down receipts to the level mentioned; but generally speaking, the quicker the service the more people are encouraged to travel, and I am strongly of opinion that it is the wisest course to cater rather in advance of public requirements than to draw big receipts per car-mile.

I do not think it is necessary for me here to discuss the advantages of tramways over any other form of mechanical traction for normal traffic conditions. There is a consensus of opinion that where traffic warrants, tramways are pre-eminent in handling such traffic, but as the economic limit of tramways has been almost reached in the provinces, we are called upon to find some method of traction less costly in construction, and at the same time cheap to work and inexpensive to maintain. Many of the progressive corporations and companies have been looking for some method of extending their undertakings into the less-populated districts in the hope of encouraging and stimulating traffic on their existing lines.

Motor 'buses have been used for this purpose, and in many cases have been abandoned after exhaustive trials, on the ground that they were too expensive to operate and maintain. It is quite true that great improvements have been made in motor 'buses during the last three years, but even now, in London (where the road surfaces are probably the best in the world for mechanically propelled vehicles), motor 'buses are noisy, unreliable, costly to maintain and operate, and generally inefficient. There are a few successful provincial motor 'bus companies, and I may instance the Scottish Motor Traction Co., which operates in the suburbs of Edinburgh. Some years ago this company came to the conclusion that short-distance traffic with motor 'buses was quite unremunerative, and having realised this they extended their operations, and now I believe their average fare per passenger is approximately 5d., and they are giving a service at about two-hour intervals. They are operating over good macadamised surfaces, and are now paying their shareholders a reasonable dividend. This points to the fact that motor 'buses will pay, given long distance fares and suitable running conditions; but it has been many times demonstrated that such 'buses are not financially successful when dealing with short-distance traffic. Omnibuses driven by electric batteries, steam, and by petrol and paraffin internal combustion engines, have been tried with the same result, and I am therefore forced to the conclusion that we must look elsewhere for economic means of extending our operations further afield.

Some 12 years ago, a system of railless traction was installed in Paris, but did not gain much attention. Since that time great progress has been made, and we now find there are, on the Continent, three systems of railless cars working successfully, both in an engineering and commercial sense. Many of the leading officials in the tramway world have examined and reported upon various installations working under these systems, and in all cases, so far as I am aware, the reports have been distinctly favourable.

The "Filovia" system, in use in Italy, is already in operation over a total route mileage of upwards of 60 miles, and is installed in the following places:—

Pescara–Castellamare and Extension	2½	km. long.
Spezia–Fezzano (Portovenere) 7½ km. working	15	„
Aquila Railway Station—Aquila Town	5	„
Siena Town and Extension	7	„
Ivrea–Cuorgne (Piedmont)	26	„
Cuneo Railway Station—Cuneo Town	3	„
Valle Intelvi	8	„
Stresa (in construction)	15	„

The "Mercédès-Stoll" system, the invention of Herr Ludwig Stoll, of Vienna, is in use at Pötzleinsdorf-Salmannsdorf district of Vienna, Weidling (near Vienna), Gmünd (Lower Austria), Budweis, and Pressburg (Hungary) in course of construction.

The "Max Schiemann" system is in use at Grevenbruck-Westphalia (short mineral line, opened in 1903), Monheim–Langenfeld, near Cologne (mixed line, opened in 1904), Veischedethal–Westphalia (goods line opened in 1904), Wurzen–Saxony (goods line, opened in 1905), Grossbauchlitz–Saxony (mill produce, opened in 1905), Lyons–Charbonnieres, France (passenger line, opened in 1905), Neuenahr–Abrweiler, Germany (passenger line, opened in 1906), and Mulhausen, Germany (passenger line, opened in July, 1908).

Filovia System.—This system has undoubtedly been brought to a degree of simplicity and reliability. The chassis of the vehicle is built with pressed steel frame, with wheel base of 11 ft. 6 in., and wheel gauge of 5 ft. 8 in. The cast steel wheel centres run on ball bearings, and the rear wheels are shod with twin solid rubber tyres and the front wheels with single solid rubber tyres. The electric equipment consists of two 12 H.P. traction motors, mounted upon the chassis. The motors drive quite independently through spur reduction gear, through sprocket wheels and chair rack, to the road wheels. With this independent drive to each of the rear road wheels no differential is necessary, and it has been found in practice that curves of very sharp radii are negotiated in an entirely satisfactory manner. The controller of the series-parallel type is fitted with magnetic blow-out, and is provided with five forward contacts and reverse. There is an electric brake and two mechanical brakes: one operated by a pedal and braking on the motor counter shaft; the other controlled by a hand lever and braking on the inner rims of the driving wheels. The chassis is fitted with a single-deck body, seating 24 passengers, and weighing, with passengers, 53 cwt. A speed of 18½ miles per hour on level roads is obtained, and half that speed up a grade of 5 per cent.

* Abstract of a Paper read before the Tramways and Light Railways Association, at the Dublin Congress. A short account of the discussion which followed the reading of the paper was given in our issue of June 17th.

Digitized by Google

The trolley, built on the "Cantono" patent, consists of an ordinary trolley boom fixed to the car by a trolley base similar to the bases used in this country on single-deck and covered cars. The trolley-head consists of a four-wheeled truck, which is affixed to the trolley boom by means of a ball socket joint. This allows the trolley-head to move easily and adapt itself to any irregularities in the overhead line. The overhead work is, to all intents and purposes, similar to the overhead work for ordinary rail traction, with the difference, of course, that there are both positive and negative wires. This construction appears to answer admirably; the trolley showing no disposition to leave the wires at high speeds, or when the vehicle has to move laterally to pass other vehicles journeying in the same direction.

Mercédès-Stoll System.—This system, as installed in Vienna, is the invention of Herr Ludwig Stoll, a leading official in the Austrian Daimler Motor Co. In this case the chassis is made of pressed steel, fitted with steel wheels which are shod with solid rubber tyres. Motors of 20 H.P. each are fitted in the hubs of the rear driving wheels, so that the motors form an integral part of the driving wheels themselves. This arrangement does away with the necessity for any mechanical transmission, and it is claimed that very little lubrication is required, as all the wheels and motors are fitted with ball bearings. The cable is carried through the interior of the axle, and the armature of the motor is fixed by means of keys on the axle itself, and so acts as the nave of the wheel. The controller is designed for six forward positions; three series and three parallel, and three positions for reverse. Three brakes are fitted, an electric brake and two mechanical brakes; and the steering is irreversible. The body in use in Vienna is constructed to seat 12 passengers, and standing room is provided for 12 more, as is the case on all Continental tramway systems. The car complete weighs 2½ tons. The trolley consists of a frame or carriage fitted with four wheels. The wheels run on the tops of the wires, and the current-collecting device is attached to the car by means of flexible cables. A pendulum weight is attached to the centre of the trolley carriage to keep the carriage balanced and the wheels well pressed down on the wires. The conducting cable is wound round a small drum which is mounted upon the chassis, and about 12 yds. of spare cable is carried which can be played out to allow the car to run on the whole width of the road. Four wires are used in Vienna. In other places where only two wires (positive and negative) are erected, when two cars, running in opposite directions meet, the drivers interchange the trolleys by means of detachable cable contact boxes, and it is said the operation does not usually take more than a few seconds.

Max Schiemann System.—The chassis at Mulhausen is of the built-up composite type, with wooden wheels. The rear wheels, which are 4 ft. 6 in. in diameter, are shod with steel tyres, but the front wheels have solid rubber tyres. One 22 H.P. motor only is used, and this is suspended from the chassis immediately behind the front axle in a manner similar to the tramway motor suspension, and the drive is by means of a pinion and gear wheel which is keyed on to the front axle. Each car is provided with three brakes, viz., electric, Bowden, and driving wheel brakes. The body is seated for 13 passengers, but as many as can get on are allowed to stand, space being provided for this purpose. The weight of the car is stated to be 2 tons 16 cwts., and a speed of about 12 miles an hour is obtained on the level. The trolley is similar to that used on our tramways, with a boom from 14½ ft. to 16 ft. in length. The trolley is fitted with two sliding contacts, and an arrangement permits the car to deviate for distances of 10 ft. on either side of the wires. The overhead work is similar in all respects to ordinary tramway practice, except that four wires are used.

Railless Electric Traction Co.'s System.—This Company, who are stated to have acquired the patent rights of Messrs. Max Schiemann & Co. in Great Britain, in September last arranged a demonstration* at the Hendon depôt of the Metropolitan Tramways Co. In this case the chassis follows the design of the usual motor omnibus chassis, and wheels with single solid rubber tyres on the front, and twin tyres on the rear, are employed. Two 25 H.P. motors, mechanically independent, each motor driving one half of the counter shaft through bevel gears, are used. A controller of the series parallel type is fixed, and foot and hand brakes are provided for the driving wheels and counter shaft. A single-deck body, with seating capacity for 24 passengers, is used. The trolley of the double pole type is fitted with a head of new design. The Company state they are about to place on the market heads of different patterns; one head carrying three trolley wheels, the two outer wheels of which are connected, both making contact with positive wires, and the centre wheel with negative wire. Another design employs two trolley wheels, one for positive and one for negative wires.

Criticism of Systems.—The "Filovia" system undoubtedly works well, and the managers and engineers of tramways who have inspected it find little to criticise; but there is a feeling that the cars are not just what we require here. The chain drive may give trouble, so it is said, but anyone who has mechanically propelled vehicles with chain drives knows well that chains receiving reasonable attention are not troublesome, and I personally cannot see any better way of transmitting power to the road wheels.

The "Mercédès-Stoll" system obviates any necessity for a mechanical drive, and this, of course, is a great advantage. On the other hand, the motors forming part of the road wheels, are subject to all shocks from road inequalities, and it would seem to be better to have them spring borne. Again, the very low speed at which the motors must work does not conduce to electrical efficiency. The trolley necessitates special suspension of the trolley wires, and as the trolley carriage is not designed to be detached from the wires at the termini, loops are necessary at the termini where four wires are used. As the great majority of lines which may be equipped on the trackless trolley system in this country will probably be built and operated by corporations and companies already running tramways and light railways, as extensions to their existing systems, it would be an advantage to be able to run the trackless cars to the central repair depôt for periodical overhaul and repair. With an over-running trolley this would be impossible, and I think this is the strongest objection that can be raised against this type of trolley.

The "Schiemann" system was, I believe, orignially designed for use in agricultural districts for carrying both produce and passengers, and the cars used in Germany are not as suitable for passenger traffic as the cars employed in Austria and Italy. The motor being mounted upon the front axle makes the steering heavy and cumbersome, and it is generally agreed that the rear wheels of a vehicle of this kind should be called upon to do the driving.

The system evolved by the Railless Electric Traction Co. is more up to date, and the Company has attempted to avoid any risk of "live" cars by designing a three-wheeled trolley head mounted upon two connected trolley booms; the two outer wheels being for positive wires and the inner wheel for the negative wire, the idea being to connect the steel frame and metallic parts of the car through the trolley wheel to the negative wire. This construction necessitates the use of three wires instead of two, and six instead of four, which, I think we shall all agree, is expensive and objectionable. The Company has devised an alternative design employing a head with positive and negative trolley wheels, and using two wires only; and an arrangement is fixed to give audible warning should the polarity of the wires be through any cause reversed.

Cost of Construction.—It is estimated that a trackless trolley system can be fully equipped, provided current is purchased from a supply authority, at about £3,000 per mile of route, but, of course, much would depend upon the local conditions in each case. Considering again the 4-mile route mentioned at the beginning of the Paper, the cost of construction would probably be as follows:—

Railless Traction.

Overhead line and cables at £1,500 per mile	£6,000
Five motor cars at £600 each	3,000
Five trailer cars at £250 each	1,250
Land and depôt	800
Spare parts, tools, &c.	950
	£12,000

Tramway.

Permanent way at £7,000 per mile	£28,000
Overhead line and cables at £1,500 per mile	6,000
Five motor cars at £675 each	3,375
Land and depôt (including rails)	2,000
Spare parts, tools, &c.	625
	£40,000

There is no reason, so far as I can see, why wooden poles should not be used, and as the average service would be 20 minutes, with a maximum of 10 minutes at certain parts of the day, the cost of the necessary cables should be light. In the estimate I have provided for a car with trailer per mile of route, and 25 per cent. spare. With railless traction a cheap corrugated iron building sufficient to protect the cars and cleaners from the weather would be all that would be necessary, and I do not see any reason why such a building should not be erected for less than the sum I have allocated. A tramway depôt would necessarily be more costly, even if a building of a similar kind were used.

Cost of Operation.—The working expenses of the "Mercédès-Stoll" system in Vienna are stated to be 4·52d. per car mile, but no

* Particulars of the demonstration and of the equipment were given in THE ELECTRICIAN, October 1, 1909, p. 1002.

Digitized by Google

conductor is employed, the driver collecting fares in addition to his other duties. The particulars are as follows:—

Current	0·40d.
Tyres	1·33d.
Wages (driver only)	1·20d.
Depôt expenses	0·26d.
Taxes, management, insurance, &c.	0·80d.
Repairs and renewals	0·53d.
	4·52d.

The "Elovia" system at Specia is stated to cost 5·645d. per mile; the tyre renewals account for 2·160d. of this sum; but the road surfaces are always very bad. The costs are set out as follows:—

Electric energy	0·415d.
General expenses	0·594d.
Renewals of rubber tyres	2·160d.
Wages and salaries	1·400d.
Maintenance of vehicles and line	0·620d.
Repairs	0·456d.
	5·645d.

The "Schiemann" system at Mulhausen is stated to cost 6·95d. per car-mile, but as the system has not been working a complete year, no returns are available giving particulars of these costs. I am informed that the current consumption is 0·8 units per car-mile, and the cost of tyres 0·84d. per car-mile.

The best way of estimating the operating cost of trackless trolley cars in Great Britain is to take the standardised form of tramway accounts, and set out opposite each item the average working expenditure on tramways in this country, and place opposite the estimated expenditure for running a system of railless cars. The author sets out the expenses in this way in the Paper, and the total are as follows:—

	Tramway.	*Railless.*
Traffic expenses per car-mile	2·806d.	2·724d.
General expenses per car-mile	0·786d.	0·411d.
Repairs and maintenance per car-mile	0·902d.	1·779d.
Power expenses (at 1¼d. per unit) per car-mile	2·000d.	1·250d.
Totals	6·494d.	6·164d.

The difference under traffic expenses is entirely accounted for by cleaning, salting and sanding tramway track (0·082d. per car-mile). The difference of 0·375d. under general expenses, in favour of railless traction, is due to rates and taxes averaging 0·500d. per car-mile in the case of tramways, as against 0·125d. for railless traction.* The items under repairs and maintenance showing a difference between the two systems are: permanent way (0·201d., tramways only), electrical equipment of line (tramways 0·125d., railless 0·187d.), cars (0·527d. tramways, 1·543d. railless), miscellaneous equipment (0·021d. tramways, 0·001d. railless). The overhead line would probably be rather more costly to maintain in the case of railless traction, as four wires would generally be used instead of two, and 50 per cent. more for this purpose has therefore been allowed. The cars themselves should be cheaper to maintain, but rubber tyres are costly, and taking some credit for saving on steel tyres, gears, pinions, motor suspensions, &c., at least 1d. per car-mile more should be set aside for the maintenance of cars than in the case of a tramway.

In putting forward the above figures, the author does not wish it to be thought that railless cars cannot be worked at a less sum than 6·164d. per car mile.

He has not taken into account the question of contributions to the county authorities for road maintenance. In county boroughs, where railless cars are run entirely within the area of such county boroughs, this question will not arise, but an attempt will probably be made by county authorities to secure clauses in any Bills which may be promoted by companies or corporations, seeking to operate outside their own county boroughs, levying a contribution for road maintenance. A similar service of motor 'buses would have to contribute nothing to road maintenance, and he cannot see why railless cars should do so. But we must be prepared to deal with this point, and any one of us concerned in the promotion of a Bill should use every endeavour to prevent such a clause being inserted.

There is a very wide field for some cheap system of traction in our country districts for dealing with goods, produce and people, and I cannot see why two different types of vehicles should not be employed—one specially equipped for dealing with goods traffic, and the other for passengers. Many of us fondly imagined years ago that we were going to obtain a very large goods traffic on our tramways and light railways. I have made repeated attempts to secure such traffic, but I am sorry to say my time has been entirely wasted, as I have been quite unable to make satisfactory arrangements. I have many times approached consignees and consignors of goods and minerals, and after showing them that I could handle their material at a cheaper rate than it was then costing them, I have had to raise the question of payment for the necessary siding into their premises, or, as an alternative, a guaranteed tonnage over a term of years.

In this district, surrounded as we are by collieries on every side, manufacturers place their coal contracts with different collieries every year, and they would not, of course, entertain the idea of being bound to one colliery. With other goods different objections were raised. First, that although we could make arrangements at one end to load the goods, they were sent to so many different places that we could not deliver. One has to recognise the truth of these arguments, and because of this I am afraid there is little likelihood of cars running upon rails getting any large amount of such traffic, except under very special conditions.

With railless cars the expense of running two trolly wires into a mill is comparatively small, and I think there ought to be a considerable volume of business of this character. In inter-urban districts, with small towns a few miles apart, I think there are numerous possibilities for any system of traction which can be cheaply installed and worked at a low cost. Under such circumstances, goods could be conveyed at a cheap rate, much to the benefit of both producer and consumer, and it is common knowledge that to-day much agricultural produce is unremunerative to the grower simply because of the difficulty of getting it quickly and cheaply to the nearest market. This traffic does not, at present, touch the railways, so that no harm would be done to them; but, on the other hand, I think railways would benefit by reason of the enhanced prosperity of the district.

Unfortunately, powers to operate railless cars have to be obtained by Parliamentary Bill. This fact is a serious stumbling block to the development of railless traction. The cost of securing the consent of Parliament may cost as much as the equipment of a small system, and promoters will therefore hesitate before embarking upon any scheme. The Board of Trade seem to look sympathetically upon railless traction, and I had hopes that Parliament would authorise the Board of Trade to grant licences, but I am afraid we shall have to wait some time before we can make an application at a very small cost to enable us to instal railless cars.

* The assumption is that the poles and wires would be assessed at one fourth the total sum that would be charged were rails laid.

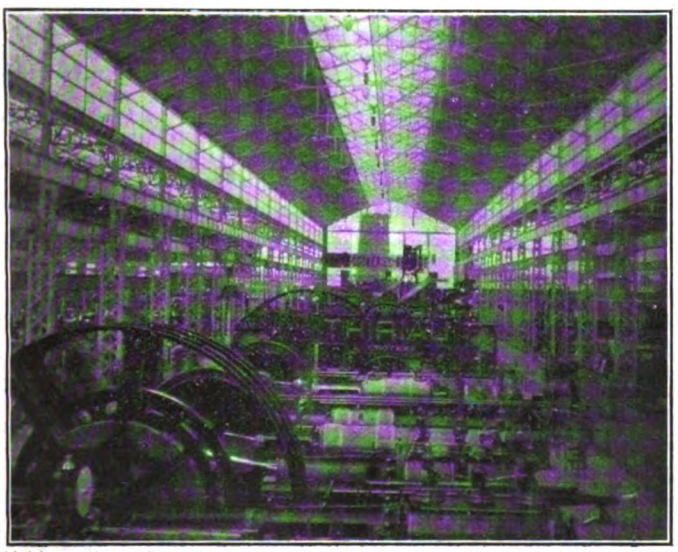
THE BRUSSELS INTERNATIONAL EXHIBITION.—III.

We have already published a summary of the principal objects of engineering and electrical interest at the Brussels Exhibition in our issues of May 27th and June 3rd. We were last week given an opportunity of visiting the Exhibition with a number of British journalists, who were the guests of the Belgian State Railways and the Commissioners of the Brussels International Exhibition. The party was officially welcomed in the British section of the Exhibition by the executive staff, at the head of which is the Commissioner-General, Mr. U. F. Wintour, who is assisted by Mr. N. S. Reyntiens. Sir Boverton Redwood, D.Sc., chairman of the Chemical Industries Committee, was also present, and personally escorted the party round the British chemical exhibits. Sir Boverton is well known in connection with British chemical industries, and his lucid explanation of the principal objects of interest in the section was greatly appreciated. There is nothing particularly electrical in this section, but it is noteworthy that the exhibit is the largest of its kind which has ever been got together. It even exceeds in size and general interest that of the St. Louis Exposition of 1905. British enterprise in this field appears to be holding its own against severe competition from foreign countries. This is particularly noticeable in the exhibit of the Burma Oil Co., whose business is based upon a world's trade in candles, and which has been developed into the supply of fuel, internal combustion engine and lubricating oils of every class. The Company operates a large fleet of steamers, and is the principal oil company operating under the British flag. While on the subject of oils, Sir Boverton Redwood directed special attention to the instruments exhibited by Messrs. Griffin & Sons, Townson & Mercer and Baird & Tatlock for testing oils as to uniformity of quality, viscosity, vaporising temperatures, flash points, &c. Upwards of 50 chemical and allied firms are represented in this exhibit, and a separate catalogue dealing specially with the exhibits has been prepared by the executive staff, under the supervision of a special editorial committee presided over by Sir Boverton Redwood. Compared with other nations, British chemical industries appear at their best, and too much attention cannot be directed to this fact, having regard to the many persistent attempts of the lay press to belittle the work of Great Britain in this important field of research.

Digitized by Google

The press visit was naturally marked by a number of functions which were arranged in honour of the delegates. The first of these was a luncheon given on June 29th by the British Executive Committee. This was presided over by the Commissioner-General, Mr. U. F. Wintour, who was supported by Sir Swire Smith, Vice-President of the Royal Commission, Sir Cecil Hertslet (British Consul-General for Belgium), the Earl of Granville, Baron Janssen (President of the Executive Committee), and a number of other officials. In the evening a dinner was given to the party, and Baron Janssen was in the chair. Much the same company sat down, but the Earl of Lytton, who is Chairman of the Executive Committee of the British section of the Brussels Exhibition, was present.

On Thursday, with their customary enterprise, the German section of the exhibition, which is presided over by Dr. Albert, entertained the delegates to luncheon in the Kaiser Hof. The object of this little function was to direct the attention of the press to the importance of the German exhibit and its outstanding excellence in the exhibition. Unfortunately, the time at disposal only permitted a cursory glance through the German section. The act of courtesy on the part of the German Commissioner was none the less appreciated, and, being as it was an isolated instance of the extension of hospitality on the part of the exhibiting nations, it was all the more noticeable. The Germans have not been satisfied at occupying an ordinary position amongst their international rivals at the Brussels Exhibition. They made a bold bid for prominence by taking a special piece of land and erecting upon it the whole of the buildings required for the different sections representative of German educa-



Electrician Photograph.

GENERAL VIEW OF ONE OF THE THREE BAYS IN THE INDUSTRIAL MACHINERY HALL, BRUSSELS EXHIBITION.

tion, art, science and industry. They are even independent of the exhibition authorities in the matter of power supply, their buildings including a special machinery hall, which contains running electrical generating plant of distinctive types to furnish energy for lighting and power throughout the German section. This example of German commercial enterprise is worthy of note at this point by British manufacturers, and should serve to impress upon them the necessity for supporting the exhibitions department of the Board of Trade to the utmost possible extent in its work in the organisation of representative British sections in these international exhibitions. We yield to none in the belief that British manufacturers, and more particularly British electrical and allied engineers, can produce an exhibit which will bear comparison with the best of any other country. At the same time, the Brussels Exhibition displays a singular lack of appreciation on the part of British engineering firms of the advertising value to the home country of a display which shall represent every phase of British activity in art and applied science. These sentiments were expressed by Lord Lytton in a speech which he made at the German luncheon. He dwelt upon the necessity for the maintenance of political peace between the two countries, but he regarded industrial and commercial rivalry as a species of warfare which, while constructive in its object, would unquestionably prove the merit of one or other of the nations to survive the effects of the struggle. He did not decry in any way the work which Great Britain was carrying on in every known sphere of human activity, but he was bound to confess that our country was deficient in matters of organisation, and also was lacking in the appreciation of the value of publicity which international exhibitions afford. He thought that this was proved by the amount of money which the German manufacturers had spent in the organising of their section, and also in the fact that the German Government contributed largely to the exhibition funds. The general opinion was that, though much money had been spent, a profitable return would be experienced from the outlay.

THE ELECTRICAL AND ENGINEERING EXHIBITS.

The majority of the British exhibits are placed under the cover of a large hall adjoining the Belgian industrial building, but the electrical and engineering exhibits have been assembled in the Industrial Machinery Hall, which is beyond the French and Italian sections, and is reached from the British hall by crossing the bridge over the Avenue du Solbosch. This sub-division of the exhibits is a little disappointing, because the result is not anything like so impressive as a collective display. We have already dealt with the principal British exhibits in the International Machinery Hall. These, from the electrical point of view, are mainly confined to a steam turbine exhibit by Messrs. C. A. Parsons & Co., and an exceptionally fine display of English machine tools, all of which are electrically driven. The latest triumph of British engineering, in the shape of the Humphrey gas pump, is given a prominent position at the top end of the hall, close to the main switchboard. This is the first public exhibit of this invention since Mr. Humphrey read his now historic Paper before the Institution of Mechanical Engineers some 18 months ago. The exhibit takes the form of a pumping plant which is designed to lift 250,000 gallons of water per hour to a height of 35 ft., the coal consumption being 1·06 lb. per pump horse-power-hour. Most of our readers will be familiar with the fact that this pump has no moving parts, such as piston, crank, flywheel, and is without non-return valve in the delivery pipe, and also has no glands. The only working parts are the water valves and the admission and exhaust valves.

The principal impression given by the exhibits in the International Machinery Hall is the preponderance of the steam turbine in modern electrical power stations. The principal French and Swiss manufacturing firms exhibit steam turbines which range in power from 3,000 kw. downwards. No particular novelties are shown, but it is interesting to observe how the various manufacturers deal with the problem of ventilation of the generator winding and the revolving field. Probably there has been no such representative collection of steam turbines since the development of the modern high-speed type with enclosed generators.

While on the subject of steam turbines, reference should be made to the Le Rond rotary engine, which is exhibited in the Machinery Hall, and which at the time of our visit was not complete. This machine is designed to develop from 700 H.P. to 900 H.P., and has one main and two subsidiary rotating pistons, which provide for five expansions of the steam. The speed is 400 revs. per min., and the working steam pressure 150 lb., with or without superheat. The machine operates in conjunction with a Westinghouse-Le Blanc condenser, and is coupled to a Lahmeyer three-phase generator. Evidently some doubts are entertained as to the smooth running of the engine, as a flexible coupling, such as is employed on most hydro-electric schemes, is placed between the rotary engine and the generator.

International Congress of Mathematicians.—The fifth meeting of the Congress, which is held every four years, will take place at Cambridge in 1912. An International Commission on Mathematical Teaching has been constituted in connection with one of the sections, and includes delegates appointed by the various governments interested in the Congress. A series of national sub-commissions has also been established to assist the International Commission. The President of the Board of Education has appointed Sir George Greenhill, M.A., F.R.S., Prof. W. W. Hobson, Sc.D., F.R.S., and Mr. C. Godfrey, M.A., to be the British delegates, and he has further appointed an advisory committee to assist the Commission in the collection of Reports and Papers on the teaching of mathematics, and this committee, which is to act also as the British Sub-Commission, has been constituted as follows :—Mr. C. E. Ashford, M.A., Sir G. H. Darwin, F.R.S., D.Sc., Mr. C. Godfrey, M.A., Sir George Greenhill, M.A., F.R.S., Mr. G. H. Hardy, M.A., F.R.S., Prof. W. W. Hobson, Sc.D., F.R.S., Mr. C. S. Jackson, M.A., Sir Joseph Larmor, D.Sc., F.R.S., Prof. A. E. H. Love, M.A., D.Sc., and Prof. G. A. Gibson, LL.D. Mr. C. S. Jackson is acting as honorary secretary to the Sub-Commission.

The Rates for Subscription to "THE ELECTRICIAN" are as under

	Year.	Half-Year.	Quarter.	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Canada	28s. 3d.	14s. 6d.	7s. 6d.	
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.	

New volumes of "THE ELECTRICIAN" commence in April and October.
(This charge includes all Supplements.)
Vols. I. to LXIV. can now be supplied. Price on application.

"THE ELECTRICIAN" SERIES OF STANDARD ELECTRICAL BOOKS

can be obtained of all Booksellers at Home, in the Colonies, and Abroad.

THE "ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. Published annually in February, corrected to mid-February. Established 1882. A very valuable advertising medium, covering the entire Industry. SUBSCRIPTION Price (which is received *in advance* up to Dec. 31st in each year for the next following edition) 8s. 6d. nett, postage 9d. extra. Published price 15s. nett, postage 9d. extra. Postage to British Colonies, 2s.; Europe, 2s.; U.S.A., 3s. 6d.; other countries, 2s. 6d. *Digest of Contents sent free on application.*

THE "G.T." GEOGRAPHICAL DIRECTORY OF THE U.K. (Electrical Section). Subscription 5s., post free.

"THE ELECTRICIAN" PRIMERS (81 Primers in all, and a GLOSSARY). Single Primers 3d. each post free. *New and Enlarged Edition in One Complete Vol. or Three separate Vols. now ready.* FULL PROSPECTUS FREE.

ELECTRIC TRACTION ON RAILWAYS. By Philip Dawson. Price 25s. nett. *Prospectus free.*

ALTERNATING-CURRENT MOTORS. By Dr. Rudolf Goldschmidt. Price 6s. 6d.

THE SHOT-FIRER'S GUIDE: A Practical Manual on Blasting and the Prevention of Blasting Accidents in Mines, Quarries, &c. By W. Maurice. Price 3s. 6d. nett.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson, M.I.E.E. *New Edition.* Now ready. Price 15s. nett.

ELECTRIC BLASTING APPARATUS AND EXPLOSIVES: With Special Reference to Colliery Practice. By W. Maurice. Price 8s. 6d. nett.

THE ELECTRIC FURNACE IN IRON AND STEEL PRODUCTION. By John B. C. Kershaw, F.I.C. Price 3s. 6d. nett.

BRAKES FOR TRAMWAY CARS. By H. M. Sayers. Price 3s. 6d. nett.

THE MECHANICAL DESIGN AND CONSTRUCTION OF COMMUTATORS. By R. Livingstone. Price 6s. nett.

THE ALTERNATE-CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. [abroad 13s.
VOL. I.—Price 12s. 6d. post free, abroad 13s. VOL. II.—Price 12s. 6d. post free,

HANDBOOK OF THE ELECTRICAL LABORATORY AND TESTING ROOM. Very fully illustrated. By Dr. J. A. Fleming. Vol. I., 12s. 6d. nett, Vol. II., 14s. nett.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming. 6s. nett.

ELECTRICAL LABORATORY NOTES AND FORMS. Arranged by Dr. J. A. Fleming, M.A., F.R.S. Single copies 4d. nett, or in dozens at 3s. 6d. nett. Complete Sets of 50 Notes and Forms, 12s. 6d. nett, or in strong portfolio, 14s. nett; or bound in strong cloth, 15s. nett. Spare Copies of Tabular Sheets, 1s. per dozen. Portfolios, 1s. 6d. each. Sectional paper, 1s. per dozen sheets. *Complete Prospectus post free on request.*

A SMALLER SET of only 40 Forms, bound strong cloth. Price 7s. 6d. nett.

CENTENARY OF THE ELECTRIC CURRENT—1799-1899. By Prof. J. A. Fleming, F.R.S. Price 1s.; strong cloth 2s. 6d.

ELECTRICITY METERS: THEIR CONSTRUCTION AND MANAGEMENT. By C. H. W. Gerhardi. Profusely illustrated. Price 9s. nett.

ELECTRICITY IN HORTICULTURE. By Prof. S. Lemstrom. Illustrated. 3s. 6d. nett.

RADIO-ACTIVITY: AN ELEMENTARY TREATISE, FROM THE STANDPOINT OF THE DISINTEGRATION THEORY. By Fredk. Soddy, M.A. Fully illustrated. Price 6s. 6d. nett.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d. Vol. II. Price 12s. 6d. *Vol. III. in the press.*

MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY. By E. Tremlett Carter, C.E., M.I.E.E. Revised by G. Thomas-Davies, A.M.I.E.E., F.C.S. Price 12s. 6d. nett.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, B.Sc., F.R.S., F.R.S.E. Price 10s. 6d.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson, M.I.E.E. Price 6s. 6d.

ELECTRIC MOTIVE POWER. By Albion T. Snell. Price 10s. 6d. nett.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Geipel and H. M. Kilgour. Price 7s. 6d. nett.

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young. Price 10s. 6d.

STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By H. K. C. Fisher and J. C. H. Darby. Price 7s. 6d. nett.

SIGNALLING ACROSS SPACE WITHOUT WIRES: THE WORK OF HERTZ AND HIS SUCCESSORS. With new Chapter on Tuning. By Dr. Sir Oliver J. Lodge. Price 5s. nett.

THE ART OF ELECTROLYTIC SEPARATION OF METALS. By Dr. G. Gore, LL.D., F.R.S. Price 10s. 6d.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s.

BEGINNER'S MANUAL OF SUBMARINE CABLE TESTING AND WORKING. By G. M. Baines. Price 7s. 6d. nett.

CARBON MAKING FOR ALL ELECTRICAL PURPOSES. By Francis Jehl. Price 10s. 6d.

"THE ELECTRICIAN" WIREMAN'S POCKET BOOK. Edited by F. C. Raphael. Price 5s. nett.

"THE ELECTRICIAN" HANDY WIRE TABLES FOR THE POCKET. By P. B. Down, Wh.Ex., A.M.I.Mech.E. Price 2s. 6d. nett.

THE RATING OF ELECTRIC LIGHTING, ELECTRIC TRAMWAY, AND SIMILAR UNDERTAKINGS. By W. G. Bond, M.I.E.E. Price 2s. 6d. nett.

DRUM ARMATURE WINDING AND COMMUTATORS. By F. M. Weymouth. 7s. 6d.

PRIMARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By W. R. Cooper. Price 10s. 6d. nett.

SECONDARY BATTERIES: THEIR CONSTRUCTION AND MANUFACTURE. By E. J. Wade. Price 10s. 6d. nett.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. Price 1s. 6d.

THE LOCALISATION OF FAULTS IN ELECTRIC LIGHT CABLES. By F. C. Raphael. 7s. 6d.

THE STEAM-ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont, M.I.C.E., M.I.M.E., &c. Price 6s. nett.

THE ELECTRIC ARC. By Mrs. Ayrton, M.I.E.E. Price 12s. 6d.

TRAMWAY TRACTIVE EFFORT AND POWER DIAGRAM. By Arnold G. Hansard, B.A., A.M.I.E.E. Price 4s. 6d. nett; in Tube, 5s.

THE BRITISH POST OFFICE TELEPHONE SERVICE. Fully illustrated.. Price 3s. 6d. nett.

INTERNATIONAL TELEGRAPH CONVENTION AND SERVICE REGULATIONS. Price 6s. nett. (LISBON REVISION, 1908.)

BOILER FEED WATER. By F. W. Anderson. Price 6s. nett.

(PRELIMINARY) WIRELESS TELEGRAPH CONFERENCE (BERLIN, 1903), PROCEEDINGS AT. Price 8s. 6d. nett.

INTERNATIONAL WIRELESS TELEGRAPH CONVENTION AND SERVICE REGULATIONS (BERLIN, 1906). With complete report of Proceedings. Price 21s. nett.

THE CLASSIFICATION OF ALTERNATE-CURRENT MOTORS. By V. A. A. Fynn, M.I.E.E. Price 3s. nett.

ELECTRIC CRANES AND HOISTS. By H. H. Broughton. *In Preparation.*

PRACTICAL TELEPHONY. By W. Aitken, M.I.E.E. *In Preparation.*

ELECTRIC MAINS AND DISTRIBUTING SYSTEMS. By J. R. Dick, B.Sc., and F. Fernie, A.M.Inst.C.E. *In Preparation.*

THE PRACTICAL WIRELESS SLIDE RULE. By Dr. H. R. Belcher-Hickman. Price 2s. 6d. nett. *Nearly Ready.*

THE MECHANICAL DESIGN AND CONSTRUCTION OF GENERATORS. By R. Livingstone. *In Preparation.*

LIGHT, RADIATION AND ILLUMINATION. From the German of Paul Högner, by Justus Eck. *In Preparation.*

"THE ELECTRICIAN" INDUSTRIAL SUPPLEMENT.

With "THE ELECTRICIAN" for Sept. 14, 1906, was issued the first of a series of "Industrial Supplements," to be published from time to time with "THE ELECTRICIAN." The fiftieth issue of the Supplement was published (Gratis) with the number of "THE ELECTRICIAN" for June 24.

The "INDUSTRIAL SUPPLEMENT" is a comprehensive record of developments in Electrical Plant, Machinery, Apparatus, Accessories, Sundries and Materials, and of their proved suitability for various Industrial purposes.

The "INDUSTRIAL SUPPLEMENT" is holed for filing or hanging, and filing covers can be supplied for holding 6 or 12 issues.

SPECIAL NOTICE.

NOW READY.—Vol. LXIV. of "THE ELECTRICIAN" (1,035 pages) bound in strong cloth. Price 17s. 6d.; post free, 18s. 6d. Now ready. Cases for Binding. Price 2s.; post free, 2s. 3d.

A complete set of "THE ELECTRICIAN" can be supplied. A number of odd volumes and some odd old back numbers, to help in making up complete sets, are also available.

STREET LIGHTING CONTRACTS.

At first sight it might be thought that the drawing up of a contract for street lighting was a simple matter. Given a type of lamp, number of hours of burning and the cost of energy, the total annual cost is at once obtainable, and therefore a suitable price may be deduced. On this basis all is well if there is no progress in the art of illumination. We live, however, in an age when conditions alter rapidly. A new lamp may be devised, or the cost of energy may fall considerably, and in any case there is ceaseless competition, so that the subject cannot be regarded as one in which the conditions are by any means fixed for any length of time.

The whole question was considered recently by Mr. JACQUES ABADY at considerable length in a Paper read before the Institution of Gas Engineers. In this Paper street lighting contracts were divided into three classes. Hitherto such contracts have taken either of two forms. The first type is a contract for the supply of energy with maintenance, the charge depending chiefly upon the amount of energy required. There are certain inherent difficulties in a contract of this kind. First of all, it rarely happens that the energy can be measured to any degree of accuracy. Approximation must be depended upon rather than measurement, as numerous meters are obviously out of the question.

Digitized by Google

The charge, therefore, generally takes the form of an annual sum per lamp, such sum including a certain proportion for the necessary maintenance. There is also some difficulty in ensuring that the condition of the lamps shall be satisfactory. As to whether this part of the contract is carried out properly or indifferently depends very much upon the conscientiousness of the supplier of the energy, as it is difficult to enforce any particular standard without taking elaborate measurements. Perhaps the chief objection, however, to this form of contract is the fact that it gives no inducement to the supplier of energy to put in newer types of lamp in place of the older types, though when a lump sum per annum is charged per lamp it may be thought worth while to put in a more efficient lamp in some cases. This, however, requires an expenditure of money, and more often than not it will be felt that the saving in energy does not justify the additional expenditure. Certainly there is no inducement to put in a lamp which gives greater illumination for the same consumption of energy. Similarly, supposing the municipal authority were to suggest a more efficient lamp taking less energy, the proposition would not be received very favourably by the supply undertaking. This state of things really amounts to a loss both to the public and to the supply authority. As a result, the public does not get the best light, and although the supplier of energy may seem for the moment to be in a satisfactory position, yet it is fairly obvious that if the light given is poor and not up to date it is a bad advertisement, and will tell against the supply authority in the long run. Instances of this kind are to be found in certain parts of London, where extremely antiquated forms of arc lighting are to be seen, but which, in accordance with the lighting contract, may still remain for many years as exceedingly bad advertisements of electric lighting.

The second type of contract is that in which the payment is for energy alone, the maintenance being undertaken by another contractor, or by the municipality itself. This form of contract is not much better than the one to which we have just referred. In some respects it is less desirable, for if the maintenance contractor neglects to keep the lamps in proper condition this may affect the supplier of energy very adversely. This is particularly the case owing to the keenness of the competition between gas and electricity for street lighting. We think it will be generally agreed that, as the maintenance of the lamps is of some importance to the supplier of the energy, it should be left in the hands of the latter. The only advantage of this second type of contract is that it enables the local authority to put in improved lamps without affecting the contract, provided the same amount of energy is taken; but it does not enable more economical lamps to be put in for the same amount of light, or permit the cost of public lighting to be reduced.

The form of contract advocated by Mr. ABADY, and with which our readers are already familiar through recent events, is that by which light is purchased instead of energy. There are certain advantages in a contract of this kind; the cost of energy has a smaller control in the problem, and thus full advantage can be taken of new types of lamp. In such cases it need scarcely be said that the maintenance is carried out by the supplier of the energy, and lamps will necessarily be maintained at such a standard as to ensure the supply of light being not less than a stipulated value. The only serious question that arises is whether the measurement of the light can form a satisfactory basis. Illumination is really what is required, but it is pretty obvious that this effect in itself would not be a suitable basis for such a contract, for the simple reason that the illumination produced by a lamp depends very much upon its surroundings. It therefore seems necessary that candle-power should be the quantity to be measured. Again, a single measurement of a lamp on a particular evening is not sufficient, as it is well known that considerable variations of a momentary character may occur. In the case of the Westminster contracts, not less than three and not more than six readings at regular intervals of not less than 30 or more than 60 seconds are to be made at each angle, and the average of the readings so obtained is to be taken. With regard to the angles, two have been selected—namely, 20 deg. and 50 deg. respectively from the horizontal. In all probability these angles will prove satisfactory. Whether the number of readings suggested will meet all requirements, it is more difficult to say. We note that the photometer may be placed at any position in azimuth, but doubtless such measurements would generally be taken along the length of the street. Certainly this ought to be the case, for the tendency is to make the lamps throw light, by means of reflectors, more particularly lengthways of the street than across it, and the measurements ought to be such as to encourage any development of this kind. Uniform illumination is what is desired, and this can only be approached either by having a large number of low-power sources, or by suitably altering the distribution curves of high-power sources so as to throw more light in dark places.

REVIEWS.

Electric Power Plant Engineering. By J. WEINGREEN. (London: Hill Publishing Co.) Pp. viii. + 451. 21s. net.

Compared with some recent works professing to deal with a similar subject emanating from the other side of the Herring Pond, this book is most disappointing. There does not appear to be any individuality or originality pointing to the author's personal experience of the matters or the subject on which he writes. The book consists mainly of descriptions of apparatus and central and sub-stations. There is nothing, so far as one can see, actually incorrect about it; but it could nearly all have been obtained from a couple of manufacturers' catalogues and the articles appearing in the technical Press describing power-plant equipments.

Even the information that *is* contained in the book is somewhat scrappy and incomplete. Although the book is supposed to deal with electric power plant engineering, there is hardly any mention of a turbo-generator, and the chapter dealing with direct-current generators does not mention any of the difficulties of operation, such as, for instance, carbon brushes on a high-speed turbine generator—in fact, it is not about generators at all. It deals mainly with auxiliary switchgear and equalising bars.

Digitized by Google

Some of the subjects dealt with are split up; for instance, in the case of converters one has to look at one end of the book for one part and the other end for the other.

Although minute instructions for starting and stopping various electrical machines are given (which work is usually done by a workman, and not by men who would read a book of this kind), matters of vital importance as regards the efficiency and cost and management of the plant itself, and the applications of the various apparatus for various purposes are barely touched upon. We should not refer to this omission had it not been that the author takes particular care to describe the comparatively unimportant part of the operation of the plant.

There is a chapter on relays which gives useful information, and also an interesting chapter on the valuable but comparatively little used alternating-current feeder potential regulator. After 23 chapters on apparatus, the author turns to central stations, and the introductory chapter, No. XXIV., gives rise to hope for better things to come; but proceeding to Chapter XXV. we are doomed to disappointment, as the descriptions of central stations are in the usual stereotyped form in which they appear in the technical Press from time to time.

The title is altogether too comprehensive, considering the contents of the book. Even as a description of electrical power plant engineering the book is quite incomplete, and, without knowing anything of the author's position or career, one is led to assume that he is treating the subject, not from a point of view of live experience but from a purely academic standpoint. In our opinion the book is dear at a guinea.

A. Hugh Seabrook.

Fire Insurance Handbook By W. S. Coles and H. S. Bell. (London: C. & E. Layton.) 15s. nett.

This book is stated in the preface to be a Fire Insurance Handbook, written for the insurance profession. It is an up-to-date compendium of the general practice and customs governing the complex subject of fire insurance, the settlement of losses alone excepted. The contents are arranged in alphabetical order, so that no index is needed. The book will no doubt be found in every fire insurance office, as well as in the office of every fire insurance broker and surveyor, as a first reference book for the classification of risks and preliminary information in the numerous points which affect the premium rates. The fire surveyor will also find the technical hints given for preparing "specifications" of no little use, as "risks" are daily becoming more and more complicated owing to the exacting requirements of the modern factory, mill and warehouse. Apart from special articles, which are for members of the insurance profession, there is a wealth of information for the engineer and architect, as well as for the commercial manager, on fire resisting construction for buildings, heating by steam and water, fire alarms, sprinklers, fire extinguishing appliances, oil, gas and electricity. The layman will also find useful articles on "Average," "Floating Insurances," "Warranty," "Insurable Interest" and other often but little appreciated points which may affect his policies more than perhaps he realises—until a loss occurs. The electrical engineer will note that electric lighting appears to be viewed most favourably by fire insurance offices; indeed, its use is insisted on in some special risks.

The wiring rules of the Institution of Electrical Engineers are printed at length, and it is stated that "they are adopted by almost all fire insurance companies." The fatal fire at Messrs. Arding & Hobbs may suggest to the offices some modification of their requirements on the lines of the older and more conservative Phœnix Rules. We have looked up a number of subjects at random in this handbook and find much special information clearly and tersely stated; but some of the technical matter necessarily already appears to require additions or amendments to bring it up to date.

The success of the book depends entirely on the reception given it by the fire insurance profession. We believe it will supply a want, and we expect a second edition will be called for very shortly.

THE PROPORTIONING OF ELECTRODES FOR FURNACES.*

BY CARL HERING.

(*Concluded from page 484.*)

Summary.—The author describes an investigation (analytical and experimental) of the principles underlying the proper proportioning of the electrodes for electric furnaces. The author's conclusions differ very considerably from former practice.

Experimental.

The need for heat conductivities being felt, the writer undertook a determination of them for graphite, carbon, iron and copper. The method used was the one suggested in his recent Paper on "A New Method of Measuring Mean Thermal and Electrical Conductivities of Furnace Electrodes."† It is based on the same fundamental principles and formulæ as those of this analysis. Briefly, it consists in operating a pair of electrodes under conditions approximating as nearly as possible those under which they should (according to this analysis) be operated in practice—namely, that the heat gradient at the furnace end shall be zero, represented by a horizontal temperature line, in which case there will be no flow of heat into or out of the furnace through the hot end of the electrode. While thus operating, the current, voltage and cold temperatures are carefully measured for various furnace temperatures. The constants given by this test are the mean values for the electrode as a whole and when operating under the proper conditions. The values are peculiar to operating electrodes, and their relations to the end values or to the mean of the values at equally spaced distances, are different for different materials. For this reason the writer has proposed the term "electrode mean" to designate them. The details of the determination of these constants are described in a Paper to be read before the American Electrochemical Society at its spring meeting. The purpose here is to compare and discuss the results, and to endeavour to point out what they teach us.

The full lines in the accompanying diagrams (Figs. 1 to 6) represent the ranges over which the results were actually measured; the dotted lines are exterpolated, and therefore are only probable values. The exterpolated values were checked at 2,000°C. and 1,400°C. by the fixed relations. Although all the electrodes were very nearly $\frac{5}{8}$ in. in diameter, they differed slightly, hence, for comparing them more correctly with each other, the results have all been reduced to an exact diameter of $\frac{5}{8}$ in. For the same reason they have also all been reduced to a constant cold terminal temperature of 100°C. As the current-densities in some of these runs were extraordinarily high, it may be of interest to mention that the electrodes behaved very well.

The experimental results are given in Figs. 1 to 6.

Carbon (Fig. 1).—As the current curve rises nearly in proportion to the temperature, variations in current affect the losses considerably, and a current considerably greater than the normal for which the lectrode was designed will tend greatly to overheat the electrode within the walls. The electrical resistivity diminishes, at first more rapidly, then less so, tending to become more nearly constant. A decreasing resistivity means that as the current heats the electrode the heat generated per inch will become less and less at the hot end and greater and greater at the cold end than it was before; hence the colder half will be heated more rapidly. This in turn signifies that the heat gradient will tend to approach a horizontal line from the hot end to near the cold one, and will then drop suddenly. This seems to be one of the causes of the burning of the furnace wall in high-temperature furnaces in which carbon electrodes are used. A falling resistivity is therefore an undesirable quality for electrodes. A rapidly rising one would be far better; this is the case with iron.

The thermal conductivity increases (it does not decrease as has been claimed by others) at first more rapidly, then less so, also tending to become more nearly constant. A rising thermal conductivity is an undesirable feature for electrode materials, as it tends to force the higher temperatures nearer to the colder end. Carbon, unfortunately, combines this feature with a falling resistivity, both of which conduce to the same undesirable result. The curves for carbon, furthermore, show that the electrode voltage, which is a true measure of the power loss, also increases with the temperature, but the rate is slower and slower, tending to constancy. The chief conclusion, as far as our present knowledge goes, is that probably no great error would be made by assuming this important quality to be practically a constant—namely, about 0·065 volt. The specific section, which is a true measure of the size of an electrode, decreases rapidly at first

* Abstract of a Paper read before the American Institute of Electrical Engineers.

† "Trans." Amer. Electrochem. Soc., Vol. XVI., p. 317.

Digitized by Google

and then more slowly, showing that carbon electrodes become relatively smaller for the higher temperatures. This is a good feature, and especially so for carbon, because such electrodes are much larger than those of other materials.

Graphite (Fig. 2).—The current curve rises more rapidly at first

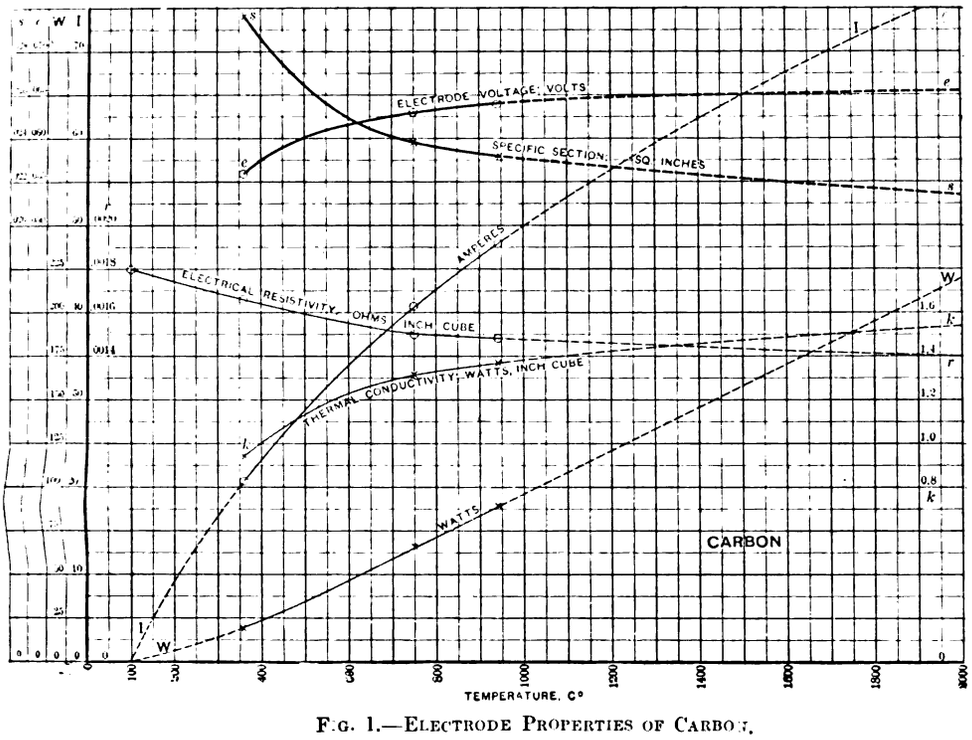

FIG. 1.—ELECTRODE PROPERTIES OF CARBON.

than for carbon, and in this respect graphite apparently possesses properties more like those of the metals. Also it would appear that a graphite electrode is more sensitive to changes of current than is one of carbon. Graphite may be placed among the metals in the desirable quality of forcing the heat back to the hot end.

In thermal conductivity graphite differs decidedly from carbon (for which this curve rises), and is like the metals. The electrode voltage falls slightly, but seems to tend to what for all practical purposes may be assumed to be constant at about 0·040 to 0·045 volts. As this is a measure of the loss, it follows that the loss per degree diminishes slightly with the temperature, instead of increasing, as it does with carbon. Graphite, therefore, is relatively to the temperature more economical of power at higher temperatures than it is at the lower ones. The specific section may be assumed to be constant at 0·007 sq. in. This means that the size of the electrode relatively to the temperature is practically the same at high and low temperatures, and does not decrease per degree, as with carbon.

Iron (Fig. 3).—The current curve shows a marked peculiarity in that it is practically a horizontal line. This is due, no doubt, to the very rapidly rising resistivity. As the hot end becomes hotter the resistance rises so rapidly that it cuts down the current again. Such an electrode is, therefore, nearly self-regulating for a constant current. In the exterpolated (dotted) parts of these curves it has been assumed that the laws of variations continue to be about the same, but it is not unlikely that with materials which melt, like metals, as distinguished from carbon and graphite, there may be decided changes of these physical properties at the melting point.

The rapidly increasing resistivity is a very desirable feature, and forces the heat back to the hot end. The thermal conductivity falls, also a desirable feature. The mean thermal conductivity is less than for graphite. This does not agree with usual comparisons, but is due to the fact that the heat is forced to the hot end more in iron than in graphite. The electrode voltage rises quite decidedly. This means that iron electrodes are relatively less economical in power at the higher than at the lower temperatures. The specific section also rises at about the same rate, showing that the size also becomes less favourable at the higher temperatures. The test bars were cold rolled mild steel.

Copper (Fig. 4).—These tests were the best of the series. The current curve rises extremely rapidly at first and then apparently tends rapidly toward the horizontal; it seems to be similar in shape to the one for iron at lower temperatures. It therefore appears that this shape may perhaps be characteristic of the metals. The electrical resistivity rises very rapidly and in virtually a straight line. The heat will again be forced to the hot end. The thermal conductivity also falls, as in the case of iron, only to a greater degree. This and the rising resistivity should make copper a very suitable electrode material for the temperatures for which it could be used. The electrode voltage rises in almost a straight line proportion. So does the specific section. It is therefore like iron in these respects.

Comparisons.—In the Paper the author plots the above curves to the same scale in order to compare the different materials with each other quantitatively. This shows, for example, that at about 1,500°C. a graphite electrode will carry over three times as much current as will one of carbon of the same size; iron will carry nearly seven times as much as carbon, whilst copper is enormously better than any of the others, its current capacity being about 45 times that of carbon. The relative inclinations of the curves of electrical resistivity make it appear as if they tended to meet at some very high temperature in a common point somewhat below graphite, at which point they would all have the same resistivity. At 1,400°C. the

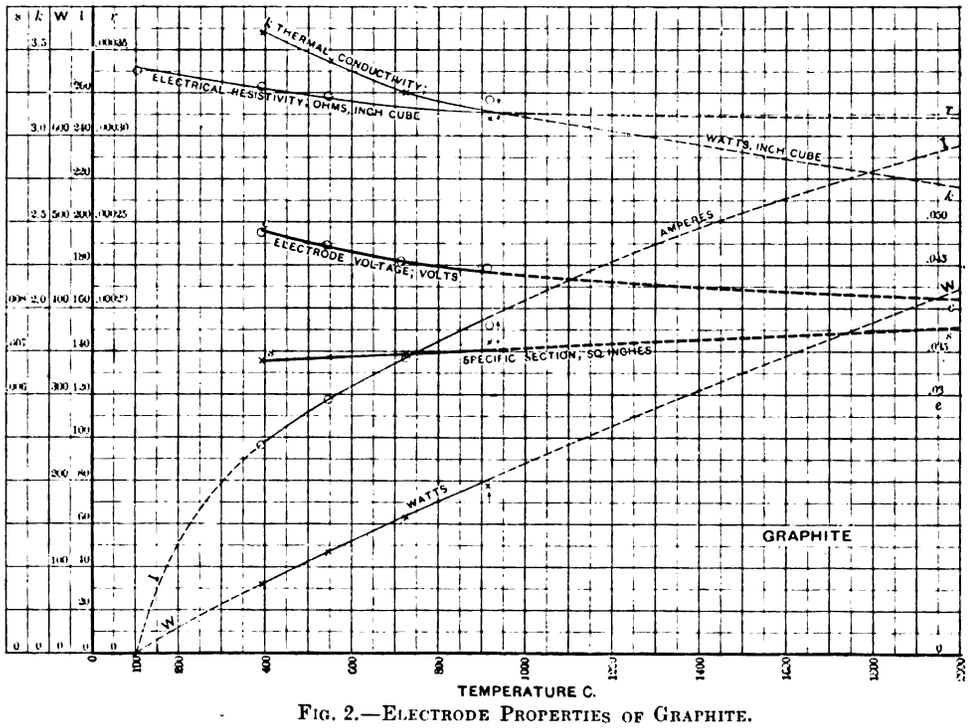

FIG. 2.—ELECTRODE PROPERTIES OF GRAPHITE.

relative values are about: Copper 1, iron 10, graphite 72, carbon 340. The thermal conductivities differ far less than the electrical resistivities; moreover, the usual order is here reversed, graphite being now next to copper. They again all seem to tend to meet in a point, this time iron being the more central one. The relative values at 1,400°C. are about: Copper 1, graphite 0·34, iron 0·22, carbon 0·17.

Digitized by Google

It may be repeated that a falling thermal conductivity is a good feature and a rising one is a bad one; also that a high thermal conductivity reduces the size of an electrode but increases the loss; hence it is a good or a bad quality depending upon which of the two economies one desires.

The curves of electrode voltage all show a tendency to rise, except for graphite, which alone possesses the good property of a falling curve. The relative values at 1,400°C. are about: Copper 1, iron 1·5, graphite 5, carbon 7·5. Specific section is a true measure of the size of an electrode when properly proportioned. For 1,400°C. the relative values are about: Copper 1, iron 6·6, graphite 14·6, carbon 45.

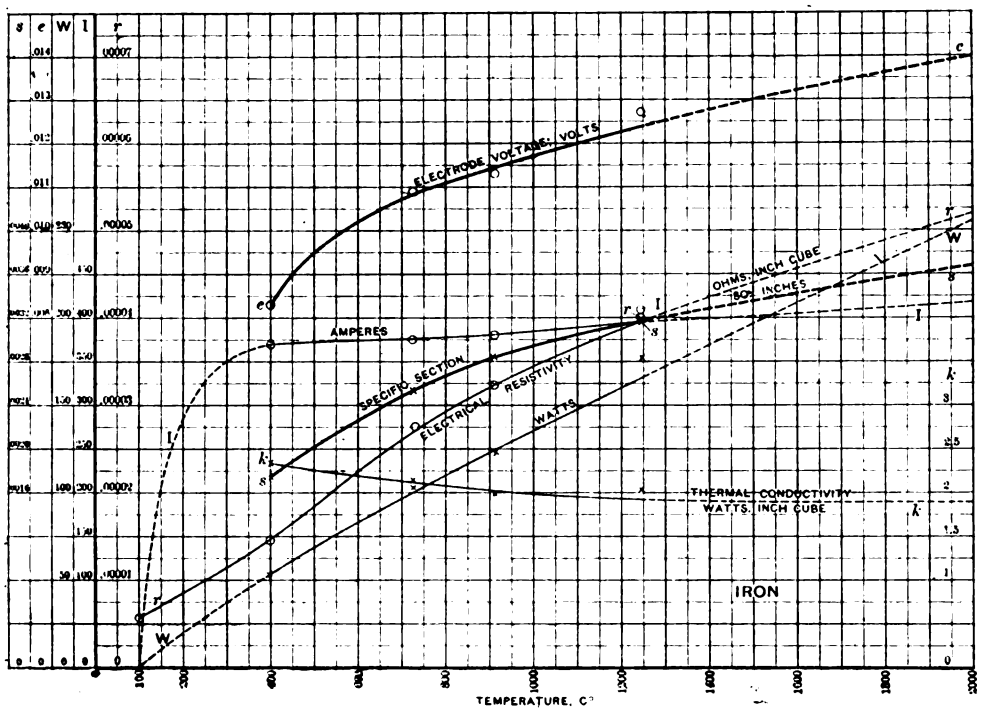

FIG. 3.—ELECTRODE PROPERTIES OF IRON.

Actual Losses and Sizes.—The electrode voltage and the specific section are the two physical constants which the writer suggests using instead of those formerly employed. Like most other physical constants, they vary somewhat with the temperature, though some of them only very slightly; but they nevertheless belong correctly under the heading of physical constants, which can for many calculations be assumed to be constant, or have the differences allowed for, just as is done with resistivities. The usually required calculations may be considerably simplified and reduced to a mere simple multiplication by using instead a tabulated set of numbers. These values are given in Figs. 5 and 6. The watts per ampere are merely the voltage between the two ends of an electrode when operating under the conditions in which there is no loss of furnace heat. Hence these are not deduced figures, but are actually measured during the test, while the figures for the sections per ampere per inch length are merely the cross-sections of the test rods divided by the length of the electrode and by the current. It will be seen, therefore, that it is not at all necessary to determine or even to consider either the electrical or the thermal conductivity in electrode problems if these simple data are at hand. In Fig. 5 the curves have been drawn to different scales, so that they are nearly superimposed, thus enabling their relative inclinations or percentage values to be compared better with each other, while in Fig. 6 they have all been drawn to the same scale, so that they may be compared quantitatively. The loss for carbon is seen to be 1·55 times that for graphite, This is interesting in view of the statements that graphite is much more wasteful of power than is carbon Also it will be seen that graphite is better than carbon in both loss and size, especially in size. Copper is best in both and carbon worse in both, while iron is closer to copper in both than it is to graphite.

This final comparison is shown in a practical way in Fig. 7, in which the sizes and losses in electrodes of the different materials are drawn to scale for a given case, in which the current is assumed to be 10,000 amperes and the end temperatures 1,400°C. and 100°C

In the first set, to the left, the length is made the same for all, namely, 10 in.—hence the sections will be different, and in the proportions of 1, 6·6, 14·5 and 45, the same as above given. The actual sizes in square inches are: Copper 1·38, iron 9·16, graphite 20·1, carbon 62. It will be seen that the proportions for carbon are practically impossible. In the second set, to the right, the cross-section is made the same, the lengths being then different. They are, in inches: 10, 1·51, 0·69, 0·22, dividing which by 10 gives their relative values based on copper. That for carbon is again impossible, as are also those for graphite, and perhaps iron. The losses in kilowatts per electrode are indicated by the lengths of the heavy black lines, which of course apply equally well to either of the two sizes for the same materials. They are, in kilowatts, about: 23·6, 15·2, 4·6 and 3·1, or in the ratio of 7·5, 5·0, 1·5 and 1. When the ratio of the section to the length is a constant, as in this case, the length increases more rapidly than the diameter. Hence, to give the carbon electrode a suitable shape for handling, it must be made still larger, and considerably so. In comparing practical electrodes this feature should be considered, and it will increase still more the difference between the sizes of the carbon and the others. It is evidently not proper to lengthen the carbon electrode of the section shown, so as to give it a better shape and to think that this merely means a small sacrifice in efficiency. Such a lengthening will evidently result in developing a high temperature within the walls, perhaps much higher even than the furnace temperature. This would be likely to burn out the furnace wall, which would be fatal to successful operation. If it is made smaller and shorter the proportions will be still worse, as is seen in the upper

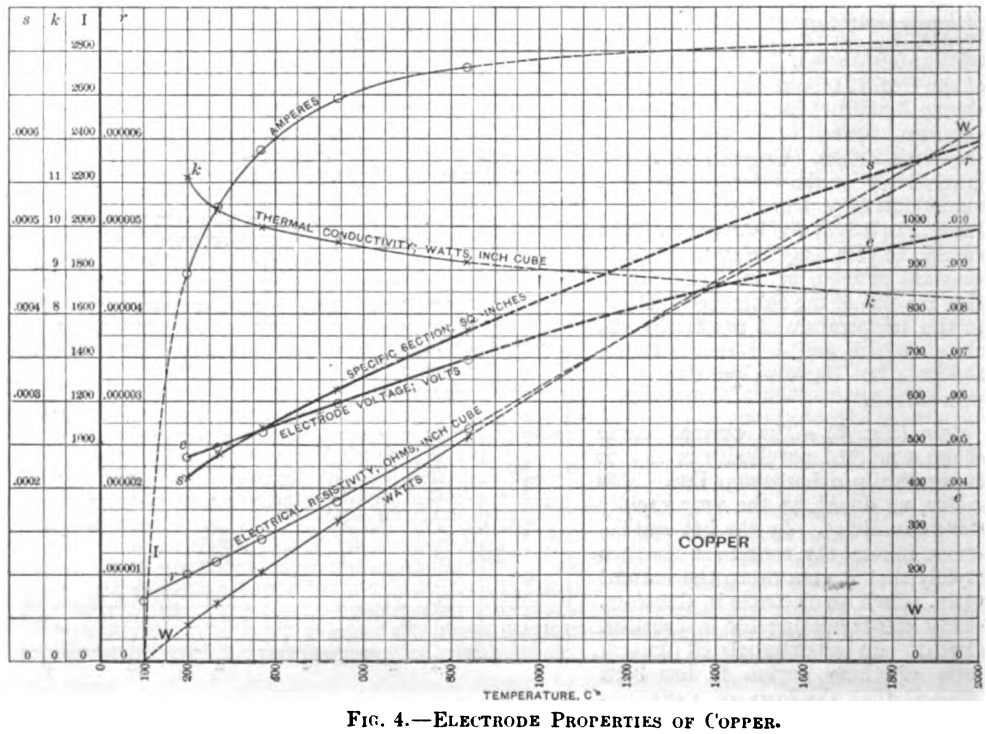

FIG. 4.—ELECTRODE PROPERTIES OF COPPER.

Digitized by Google

right-hand illustration. Consequently, there seems nothing left to do but to make it much larger and longer.

This brings out another wrong deduction which has been made by others, based on our former incorrect rules. Suppose the carbon electrode in Fig. 7 had been made with the same section but 20 in. long; it is evident that a high temperature point, higher than that of the furnace, and probably very much so, would develop at a point somewhere between the furnace, and a point 10 in. from the cold end, because 10 in. is the correct length for that section. This would burn out the walls. The conclusion drawn from our former ideas was that the current-density was too high, when the fact is that the electrode was too long for that section. The current-density had nothing to do with the failure, because if the electrode had been made half as long instead of as long again it would have been too cold and would have chilled the furnace, although the current-density was the same. Furthermore, if the electrode had been made half the section and length shown in Fig. 7, it would have operated properly even though the current-density had thereby been doubled. The current-density,

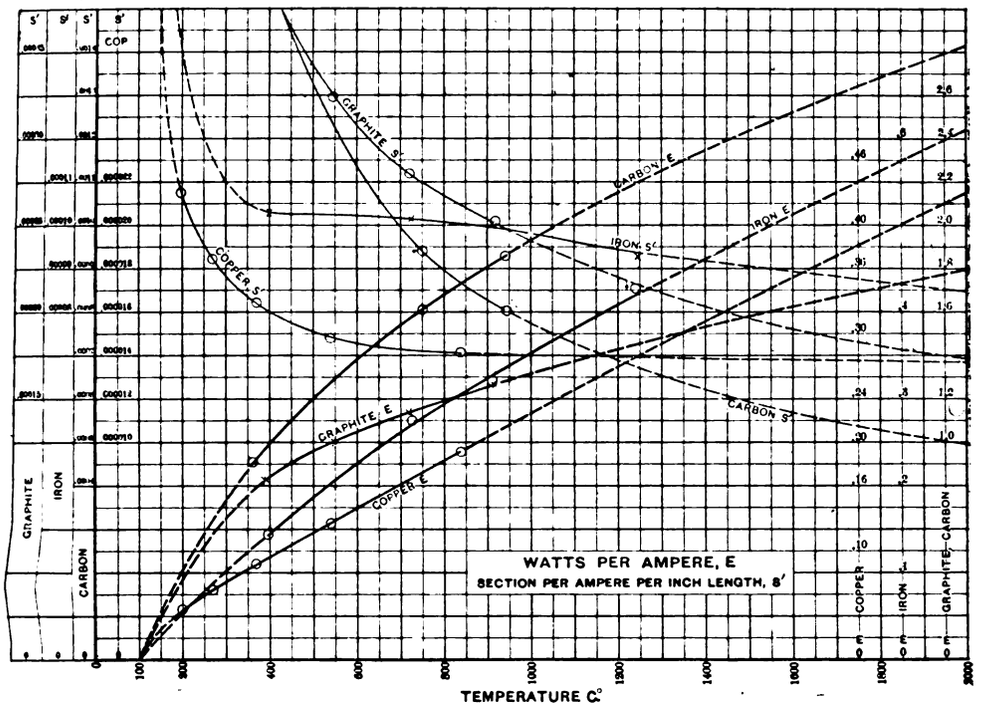

FIG. 5.—LOSSES AND SIZES. Superimposed.

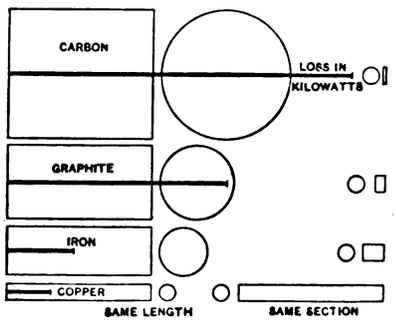

FIG. 7.—COMPARISON OF SIZES AND LOSSES.

therefore, was not the cause of failure; it has often been made responsible for faults which were really due entirely to errors in the length.

Summary of Previous Discussions.—The description of this new way of attacking the problem of the proportioning of electrodes, given by the writer briefly in May, 1909, and more in detail in October, 1909, has given rise to long discussions and attacks. An important part was an ingenious graphical method devised by Dr. A. E. Kennelly,* for representing and studying the relations of the quantities involved. Concerning the temperature correction, Dr. Kennelly has shown in a very able Paper† that under certain approximate premises (including a uniform fall of temperature in the electrode) this correction factor is zero when the electrical resistivity varies according to a straight line law. The correct mean value then is the arithmetic mean between the two extreme values at the two end temperatures. Also that the same is true when the thermal resistivity alone varies in this way. Also that when both vary in this way the total loss is least when half of the heat flow at the cold end is joulean heat and the other half is conducted from the furnace.

Dr. E. F. Roeber* has attempted the complicated mathematical solution of the case when both conductivities vary according to a straight line law, and has carried it up to, but not including, the integration. Although this unfinished formula is probably too complicated for use in practice by engineers, it shows that for given materials at stated temperatures the correction factor is merely the numerical coefficient, and that the relations between the variable factors remain the same. Dr. Roeber also finds that when the electrical conductivity is constant and the thermal conductivity alone varies by a straight line law, this complicated formula reduces to the simple original one in the writer's Paper. Dr. H. C. Richards† gives a very interesting solution of the integration for the complete case when both conductivities vary by straight line laws, and gives the first two terms of the series of coefficients. This enables the correction factors to be determined when the conductivities and their variation with temperature are known.

CORRESPONDENCE.

A TELEPHONE RELAY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. S. G. Brown has discovered quite a new field relating to telephone relays and microphones. I can only congratulate him, with the greatest enthusiasm, so much the more as he had reached his eminent success with the hardest work, probably without the modern aids, without using any barretter measurements or oscillogram records. As I am working on the trans-European (especially London–Constantinople) telephone transmission, permit me to point out some questions relating to long-distance telephony.

GÁTI'S MICROPHONE. DECKERT'S MICROPHONE.

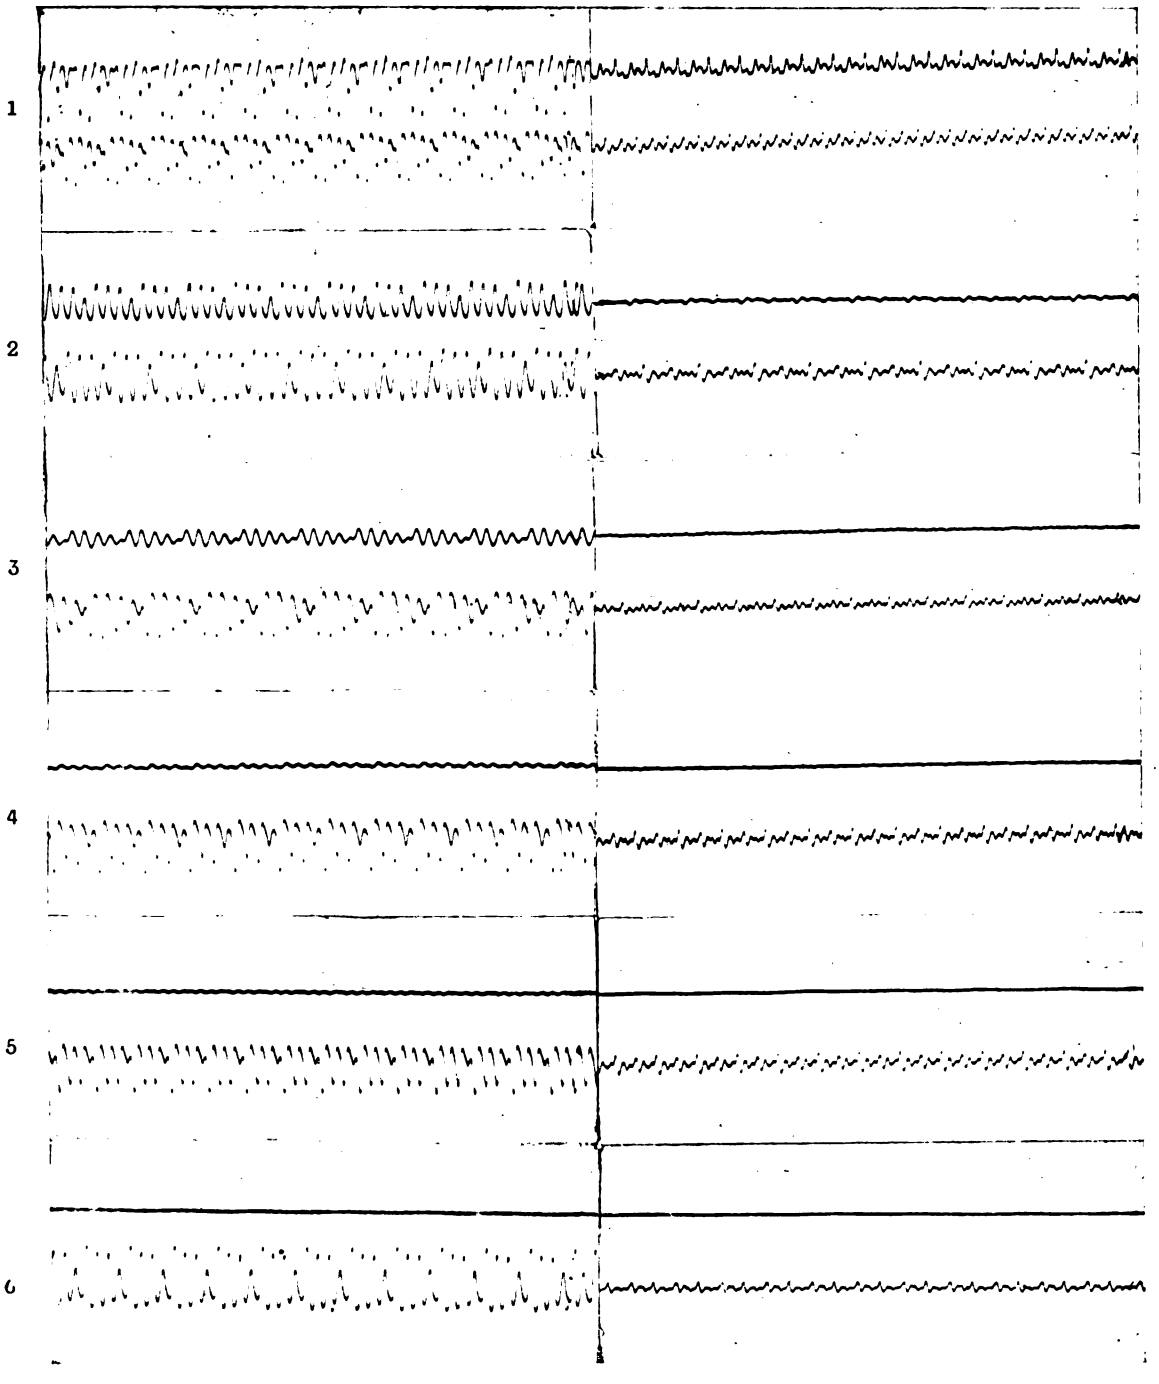

FIG. 1.—MICROPHONE RECORDS.

Table I.

Gáti's microphone.	Deckert's microphone.
The letter *a* (Hungarian).	
In the single oscillograms the upper one is the in-coming current, the lower one is the out-going current.	
1. 404 km. line: 8 km. paper cable and 4 mm. diameter bronze wire aerial.	
2,364 microamperes were received from 16,625 microamperes outgoing current with aid of Gáti's microphone.	878 / 6,125 the same relation with aid of Deckert microphone (comparison).
2. 922 km. = 8 km. cable, 4 mm. aerial.	
1,484 / 17,500 microamperes;	297 / 7,000.
3. 1,188 km. = 8 km. cable, 4 mm. aerial.	
721 / 15,750 microamperes;	191 / 5,250.
4. 1,592 km. = 16 km. cable, 4 mm. aerial.	
265 / 18,025 microamperes;	127 / 7,000
5. 2,110 km. = 24 km. cable, 4 mm. aerial.	
159 / 16,625 microamperes; the incoming current is not measurable.	
6. 2,514 km. = 30 km. cable, 4 mm. aerial.	
50 / 21,875 microamperes. Good acoustic result with Gáti's microphone.	Nothing to be heard from Deckert's microphone.

Digitized by Google

The impression of Mr. S. G. Brown, "that the carbon transmitter has been developed to its full extent," seems to be incorrect. I will not mention Messrs. Egner and Holmström, but my microphones, which are water-cooled, work with 1 ampere and speak to a distance of 2,500 km. on a 4 mm. diameter bronze wire circuit. The records are shown in Fig. 1 and Table I.

A 2,500 km. 4 mm. circuit corresponds to $\beta L = 10\,4$. instead of 3-3·5; the resistance of this circuit ($w = 10\,4$) is 15,000,000 ohms, instead of 15,000 ohms with the former microphones. That is, the new microphones overcome a line resistance which is 1,000 times more than before.

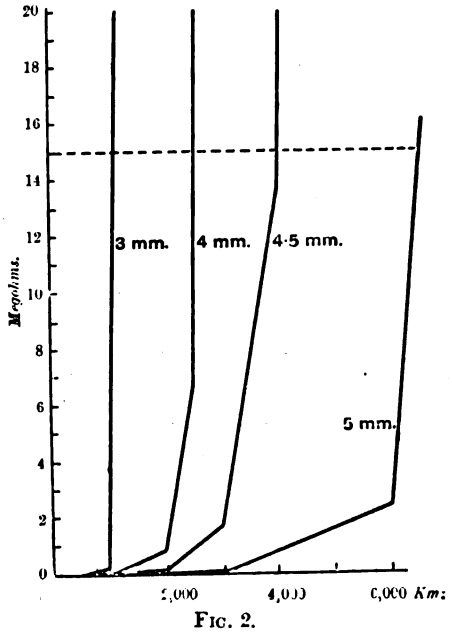

FIG. 2.

According to Fig. 2, 15,000,000 ohms resistance represents 4,030 km. 4·5 mm., or 6,500 km. 5 mm. circuit.

I am not yet satisfied with these results. It is true "that ceaseless efforts have been directed to this end by the engineers of the large telephone companies," but without success, the English National Telephone Co. excepted. But these companies were always shy regarding quantitative measurements, and the greater number of them work still with values of direct-current resistance and number of turns of the coils, instead of high-frequency resistance and self-inductivity.

I show in Fig. 3 and Table II. some records of disturbing currents which occur on the best Hungarian lines, measured with alternating current and inspected from time to time at regular intervals. What strange, disturbing currents can run over lines which are never examined from this standpoint. Over 1,000 km. (4 mm. wires) these disturbing currents have a greater value than the talking currents themselves. What does a telephone relay do now? It strengthens the disturbing currents and produces at the end of the circuit a terrible noise, in which the speech is not to be understood.

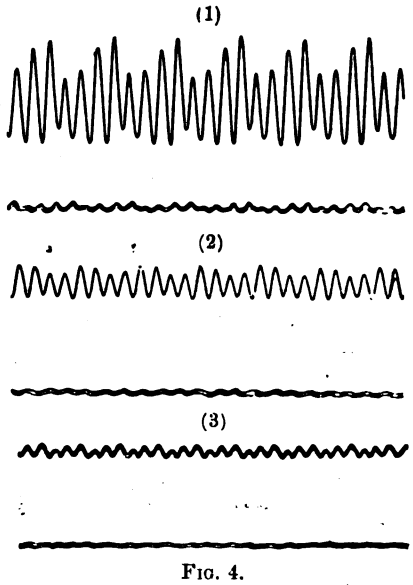

FIG. 4.

Table III.—*Records of the Letter a (Hungarian) over Lines with aid of Gáti's Telephone Repeater Relays (upper ones) and without Relays (the lower ones).*

1. 1,300 km. line (4 mm.).
2. 1,700 km. line (4 mm.).
3. 2,100 km. line (4 mm.).

The relay was connected after 900 km. Gáti's microphones were used.

Therefore the Americans use telephone relays which are actuated from the *strong* talking currents. I have also constructed some types of this relay. Fig. 4 and Table III. are the records.

My opinion is that the relay of Mr. S. G. Brown (his Fig. 4) for this purpose is not yet applicable.

The new microphones will hold very good services. I should be very glad to have some measured data for comparison. If they work over 15 megohms it would be very useful to apply them to the London-Constantinople line. I should be pleased to try them over a 3,000 km. line.

For alternating (high-frequency)-telegraphy I find the

(1)

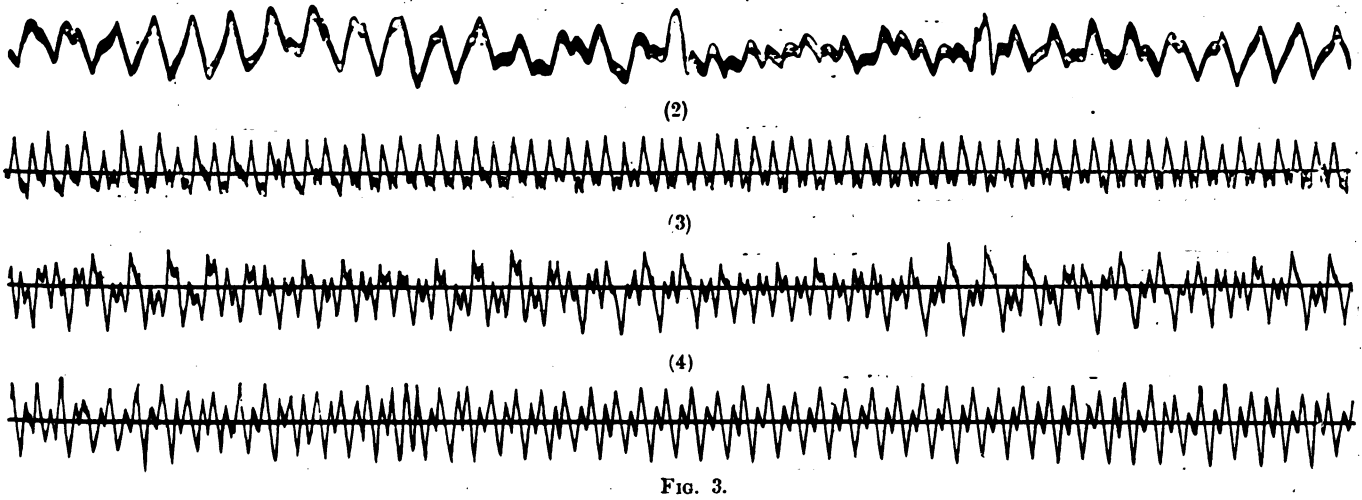

FIG. 3.

Table II.—*Disturbing Currents on Various Telephone Circuits.*

1. 10 mm. = 126 microamperes. 2. 10 mm. = 360 microamperes. 3. 10 mm. = 360 microamperes. 4. 10 mm. = 36 microamperes.

Digitized by Google

relays of Mr. S. G. Brown a wonderful help. Working on modern (highly self-inductive) cables, the resonating effect shuts out entirely the disturbing currents; in this case, with aid of the relay, it is possible to actuate, for instance, a Siemens-Halske or Creed rapid-printing set. What it all means I presume it is not necessary to explain more elaborately.—I am, &c.,

Budapest, VI. Hajós u. 33-35, June 25. BÉLA GÁTI.

LEAKANCE IN LOADED TELEPHONE CABLES, AND THE ATTENUATION COEFFICIENT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Dr. Ebeling, in a recent communication to the "Electrotechnischer Verein,"* has drawn attention to the effect of leakance on the value of the attenuation coefficient β, as especially evident in circuits where conductors of large section are adopted, and the following treatment of the subject, which has been for some considerable time on the tapis at Messrs. Siemens Bros. & Co.'s cable works, may not be inopportune at the present moment. Let the electrical values of the cable per unit length, determined at the periodicity and current strength which are assumed to represent the equivalent of the complex telephonic currents, be—

R = the loop resistance of the conductor in ohms,
r = the loop resistance of the loadance in ohms,
K = the wire to wire capacity in microfarads.
S = the leakance, wire to wire, in micromhos,
L = the inductance of the loop in henrys, which is that of the cores plus that of the loadance,
$p = 2\pi n$, where n is the frequency (750 ~ is that adopted by the British P.O.).

Then if pL and pK are large compared with R and S respectively, the formula for the attenuation coefficient becomes

$$\beta \cdot 10^3 = \frac{R+r}{2}\sqrt{\frac{K}{L}} + \frac{S}{2}\sqrt{\frac{L}{K}}.$$

As the loading coil is usually of a given size, its time constant, or its reciprocal r/L, may be taken as a constant, the inductance of the core being negligible in comparison with that of the loadance. It has also been found by actual testing that for any given material the ratio of leakance to capacity at any given frequency, or S/K, is also a constant; and converting the above formula we find

$$\beta \cdot 10^3 = \tfrac{1}{2}\sqrt{\frac{K}{L}} \cdot \left[R + \left(\frac{r}{L} + \frac{S}{K}\right) \cdot L\right].$$

Differentiating with respect to L, and equating to zero, the minimum value is shown to occur when $L = R \Big/ \left(\frac{r}{L} + \frac{S}{K}\right)$, in which special case

$$\beta \cdot 10^3 = R\sqrt{\frac{K}{L}}.$$

Inspection of these formulæ shows directly that there is a definite limit to the improvement obtainable by loading and how important it is, especially when R is small, to make the values of r/L and S/K as small as possible.

In the Channel telephone cable recently laid by Messrs. Siemens Bros. & Co., r/L was 55, while S K for ordinary G.P. cores is about 115. S K has been determined for numerous cores at 750 ~, of which the following are instances:—

G.P. cores of various dimensions	111 to 120
A special dielectric	17 to 30
Solid paper under lead	11
Paper and air with tinfoil under I.R.	6
Vulcanised indiarubber core, new	132
Vulcanised indiarubber core, about five years old	240

These values were obtained by a bridge method, which I find, from a recent conversation with Mr. Campbell, of the National Physical Laboratory, was described by M. Wien in "Ann. d. Physik u. Chemie," 1891, XLIV., p. 705, and is that given in Mr. Campbell's communication to THE ELECTRICIAN for December 10, 1909.—I am, &c.,

Woolwich, June 30. F. JACOB.

ATMOSPHERIC POTENTIALS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your article on "Electricity in Agriculture," in your issue of June 10, experiments are described in which kites were used to collect atmospheric electricity. Dr. Höstermann, in referring to these experiments, estimates the potential at a height of 800 ft. at a value of 25,000 volts and bases this figure on tests made at smaller heights with instruments reading up to a maximum value of 5,000 volts.

Dr. Höstermann is probably overestimating the potential at these heights as it is shown in experiments recently carried out by us, and published this year,* that the potential gradient is considerably greater near the surface of the earth than at great heights, and that on this account estimates of the value of the potential at any height based on the values of the potential gradient measured at lower levels and assuming proportionality between the potential and height from the ground would give values of the potential exceeding those actually existing.

Our tests showed that the potential at 800 ft. was about 15,000 volts and that values of 25,000 volts were reached at heights of 1,500 ft. to 1,800 ft. The greatest potential recorded by us was 40,000 volts at about 3,000 ft.

Our experiments are being continued, and we hope to publish further results shortly.—We are, &c.,

W. MAKOWER.

FISCAL POLICY AND THE ELECTRICAL INDUSTRY,

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have seen the letters in THE ELECTRICIAN in reply to mine. No one has taken up my challenge, as I knew from a long experience of such correspondence no one would. It is impossible for any one who realises that imports of goods can only be paid for by export of goods; and consequently that if, by a duty, you stop goods from coming in, you will stop the goods that used to pay for them from going out; that is to say that the employment you give with one hand you take away with the other—I say it is impossible for anyone who realises this to show that Tariff Reform would increase employment. I have shown how it would diminish it, and till someone shows how it would increase it that proposition stands. Protection would make the present unemployment worse. I ask your readers to observe that no one has taken up my challenge, and to draw their own conclusions.—I am &c.,

Birmingham, July 3. GEORGE HOOKHAM.

BOOKS RECEIVED.

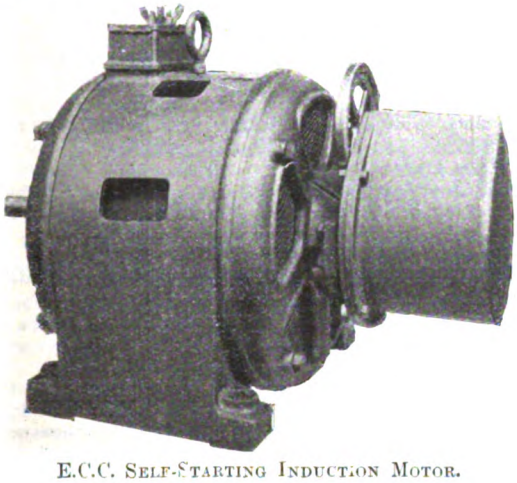
LIBRARY OF THE UNIVERSITY OF

A NEW SELF-STARTING INDUCTION MOTOR.

The Electric Construction Co., of London and Wolverhampton, have been experimenting for some time past with a new type of three-phase motor, the principal points of which are the absence of brushes, slip-rings, rotor cables or outside starter, and which, it is claimed, possesses all the well-known good characteristics of the wound rotor type without its drawbacks. The peculiar features of this new machine (which has been designed and patented by N. Pensabene-Perez) are the method of fixing the resistances to the rotor and the arrangement for cutting them out while the machine speeds up at starting. When the machine works at full speed there are no rubbing contacts whatever, so that no lifting or short-circuiting plugs or similar complicated arrangements are necessary. The revolving resistances are very compact, of strong mechanical construction, are totally enclosed in a cast-iron case, and are cut out either by hand or automatically. An important feature of the machine is that, being started through a large number of steps (from 20 to 30 per phase), there is no sudden fluctuation of the current at



E.C.C. Self-Starting Induction Motor.

starting, but a gradual variation by small steps from the starting to the running value. The automatic type, considering the simplicity of its construction, is an important step forward in the development of induction motors.

A long-distance control, as found necessary in the many applications of electrical drive, is in this way accomplished at small expense, and with the most reliable means, by the simple operation of closing the stator main switch. The automatic type, being controlled by the speed, lends itself to a simple solution of the problem of preventing a rush of current during the starting period. In fact, by a rational choice of spring-tension, frictional resistance and value of centrifugal forces, it is possible to keep the current approximately constant while the machine is speeding up, thus accomplishing what many complicated devices, in the case of hand control, are supposed to do. This motor is, from these various causes, less expensive than the ordinary slip-ring type, and, moreover, no starter or rotor cables are necessary. These merits point to the success of the new type.

BOROID, A SUBSTITUTE FOR CELLULOID.

On Saturday last a demonstration to press representatives was given of the properties of a new substance which is intended to take the place of celluloid, particularly for cinematograph shows. This has been dubbed "Boroid" and is being exploited in Great Britain by the Benobor Synd. Various thicknesses of the new material were subjected to tests which, while productive of fire in the case of celluloid samples, proved the complete non-inflammability of "Boroid." Lighted matches, cigarettes, cigars placed against the substance produced no more than a black smoke, there being no sign of flare or flame. The material also withstood successfully the exceptionally severe test of the heat rays from the condenser in the lantern; the film was clamped in "the gate," and while stationary, the full rays of the lamp were turned on to it. In ordinary cinematograph work the film is kept constantly moving, and the shutter before the condenser is never raised until the film is in motion; similarly it is lowered before the film is stopped. The "Boroid" specimen withstood the concentrated rays of a 60 ampere arc light for 10 minutes, and when examined showed no sign of burning, blistering or discolouration of any kind. The celluloid specimen subjected to the same test fired in 2 seconds. The positive carbon, while red hot, was also held against the same piece of film, which merely melted and gave off a thin white smoke. The material has been produced mainly with the idea of its taking the place of ordinary celluloid in cinematograph films, but we understand that it can be moulded into any desired shape. Samples of the material stamped out in rectangular plates about $\frac{1}{8}$ in. thick to act as a substitute for window glass were shown. The material is stated to be a good insulator, and steps will be taken to produce imitation ivory and porcelain specimens for electrical accessories.

SOUTH AFRICAN ELECTRIC LIGHTING AND POWER REGULATIONS.

On the advice of the Executive Council, the Government of Cape Colony has made additional regulations under the Electric Lighting and Power Act of 1905 for securing the safety of the public, and also certain alterations to existing regulations. The added and altered regulations, which are set out below, came into force on May 1st:—

Additional Regulations (for Motormen).

1. No person under 21 years of age, and no person who is not physically fit, and has not had actual experience in driving as learner, and instruction in the working of all appliances under the driver's control over a period lengthy enough to ensure his complete familiarity with their functions and use, shall be employed as a motorman or be permitted to operate an electric tramcar.

2. If it shall appear, after inquiry made, that any accident has occurred through the default of a motorman, the Government may call upon the undertakers to dismiss such motorman from their service as motorman, in which case he shall not be re-employed as a motorman, except with the consent of the Government first obtained.

3. The Government Electrical Inspector, or any person authorised by him in writing under his hand, may from time to time take such steps as he may deem necessary to assure himself that any motorman is properly qualified for the performance of his duties by requiring such motorman to operate one or more of the appliances on an electric tramcar, or otherwise to test his fitness as a motorman within the requirements of the regulations, and if the motorman is found to be unfit for such duties, the undertakers shall thereupon be prohibited from again employing him as motorman until he is properly qualified.

Alterations to Regulations.

Section 2, sub-section (3).—Where the supply is for incandescent lamps in series:—

(*a*) The consumer's wires forming the connections to the incandescent lamps, or otherwise, in connection with the supply, shall be completely enclosed in strong metal casing, and this casing, together with the switches and lampholders, if metallic, shall be efficiently connected with earth.

(*b*) Switches, efficient fuses or other automatic cut-outs to protect the circuits from excess of current shall be provided, and all switches and cut-outs shall be so enclosed and protected that there shall be no danger of any shock being obtained in the ordinary handling thereof, or of any fire being caused by their normal or abnormal action.

Where the supply is for any special purpose other than those above-mentioned or where the pressure of the supply exceeds the limits of medium pressure, it shall be subject to such other regulations as the Governor may from time to time prescribe.

4. An extra high-pressure supply shall not be given to any consumer's premises other than a factory, a workshop, a mine, a quarry, electric traction works, water works or sewerage or drainage works, and no such supply shall be given except with the consent of the Government and subject to such regulations as the Governor may prescribe.

16. Every support for an overhead line shall be of durable material and shall be properly stayed against forces due to wind pressure, change of direction of the line, or unequal lengths of span. The factor of safety shall be for overhead lines at least 5 and for iron or steel structures at least 6, taking the maximum possible wind pressure at 30 lb. per square foot.

27. Application for permission to employ any overhead line for high pressure or extra high pressure must be made to the Government, and, if approved, such special regulations shall be prescribed by the Governor as he may consider necessary or desirable in each case.

34. Sub-stations shall be established in suitable places, and shall be in the sole occupation and charge of the undertakers. Sub-stations shall be erected above ground wherever possible, but where necessarily underground due provision shall be made for ventilation and drainage.

45. If any consumer is dissatisfied with the action of the undertakers in refusing to give, or in discontinuing, or in not recommencing the supply of energy to his premises, the wires and fittings of the consumer shall, on his application, and on payment of the prescribed fee, be tested for the existence of leakage by the Government electrical inspector; and if the inspector's report is favourable the supply shall not be withheld by the undertakers by reason of supposed leakage. This regulation shall be endorsed on every notice given under the provisions of either of the two last preceding regulations.

48. Where the pressure of a supply between the adjacent conductors of a three-wire system of mains exceeds 125 volts, the intermediate con-

Digitized by Google

ductor shall be connected with earth, in accordance with the following conditions :—

(*a*) The connection with earth of the intermediate conductor shall be made at one point only on each distinct circuit, namely, at the generating station, sub-station or transformer, and the insulation of the circuit shall be efficiently maintained at all other parts.

(*b*) The current from the intermediate conductor to earth shall be continuously recorded, and if it at any time exceed one thousandth part of the maximum supply current, steps shall be immediately taken to improve the insulation of the system.

ELECTRIC FOUNTAINS.

Illuminated electric fountains are now no novelty, and many have found their way into the houses of the wealthy and into restaurants in most great cities. An electrically operated fountain appears, however, to be something new, and the idea of utilising a small motor-operated pump to circulate water round and round an ornamental basin via a number of jets should appeal to many. The Electric Fountain Co. have introduced a fountain which employs a vertical spindle motor and a valveless rotary pump for throwing water upwards from a number of jets grouped in a pleasing fashion.

Electric Fountain.

The same water is kept constantly on the move, and the fountain is therefore independent of the supply mains. The power consumption is about 60 watts and either alternating-current or direct-current motors can be used. The adjoining illustration shows that the fountain is compact and ornamental in appearance.

PARLIAMENTARY INTELLIGENCE.

P.O. TELEGRAPHS AND TELEPHONES.

In the House of Commons on Friday a discussion arose on the three reports of the Public Accounts Committee, and in reply to some criticism of the Post Office accounts,

The Postmaster-General (Mr. H. Samuel) said that when the telegraphs were taken over from the companies by the State in 1870 Parliament voted £10,000,000 for the purchase and development of the system, and that sum, having been voted from borrowed moneys, had been regarded as capital expenditure. It should have been repaid year by year out of the profits of the telegraphs, but as they had not yielded a profit the £10,000,000 stands as capital liability. As soon as the purchase was complete, and large extensions had been made, the telegraphs reverted to the normal system of the Post Office, and all the future extensions of the system were paid for out of the annual vote. Therefore, no addition was made to the original capital account. There was no concealment as to the loss on the telegraphs. The total deficiency at Dec. 31 last was £1,046,757. The relation of the Post Office to the telephones were at the moment much the same as to the telegraphs when they were taken over by the State. Vast sums were being expended on the creation of a Post Office telephone system, and other vast sums would be required in the next two or three years to pay the National Telephone Co. what is determined to be the value of their plant. So long as that immense capital expenditure was being made it was obviously impossible that it should be defrayed out of the annual vote, and, therefore, it was essential that there should be a capital account to start the P.O. telephone system. While a capital account was created for the telephones, whereas it did not exist for the present extension of the telegraphs, complication was created, as it was difficult to decide in any given case how much expenditure on an underground cable used by both telegraph and telephone should be treated as being for the telegraph, and so paid out of the annual vote, and how much for the telephone, and so provided for out of the telephone capital account. The matter could not be treated as a whole and put into capital. If that was done it would mean the re-creation of the capital account which Parliament dispensed with 40 years ago. If they put it all to annual expenditure they would be giving a false impression of what was the actual cost of creating the Post Office telephone service. They must discriminate. As soon as the National Telephone Co.'s system had been purchased by the Post Office, and the initial capital expenditure had come to an end, then, as in the case of the telegraphs, a sinking fund would be created, and the telephones, as the telegraphs, would revert to the normal system of finance, and annual expenditure, whether for permanent or for temporary purposes, would be met out of the annual votes of Parliament. In the matter of submarine telegraphs the Post Office acted as agent for the cable companies and paid over to them the amounts received, less Post Office charges.

POST OFFICE AND NATIONAL TELEPHONE CO.

In the House of Commons on Tuesday the Postmaster-General stated, in reply to a question, that the general conditions of the purchase of the National Telephone Co.'s plant were settled by the agreement of Feb. 2, 1905. The purchase will take effect from Dec. 31, 1911. Arrangements were being made to ensure the transfer on or as soon as possible after the date of purchase. The preparation of an inventory of the company's plant had been discussed with the company, and it was hoped that it would shortly be put in hand, and that it would be found possible for the Post Office check on the inventory to proceed concurrently with its preparation.

LONDON ELECTRIC RAILWAYS AMALGAMATION.
